Dr. Petch of Ceylon, surely one of the most voluminous writers on mycological topics, continues his monumental series of studies in entomogenous fungi, dealing in the present paper with *Aegerita Webberi*. The same author also contributes an interesting paper on Matula. Dr. Petch's line-drawings are models of what such illustrations should be.

Miss Lorrain-Smith's note on lichen-dyes will be of use to the many people nowadays who are interested in the home-dyeing of hand-woven fabrics. From time to time, controversy has arisen as to the possible harmful effects of feeding bunted grain to stock, and as the result of thorough trials, Mr. Dobson is able to show that, from the point of view of the practical stock feeder, the danger is negligible.

The introduction of any new fungus pest is of importance, more particularly when, as in the present case of the downy mildew of the hop (*Pseudoperonospora Humuli*), every stage of its invasion of England is known. Mr. Ware has discovered the interesting fact that this fungus can overwinter in the rootstock, and from that region invades developing shoots in early spring. An interesting paper by Mr. Maxwell and Dr. Wallace deals with the classical disease of black rust of cereals, *Puccinia graminis*, which was one of the first species of fungus in which strains specialised to particular hosts were described, and five of these (sp. f. Tritici, Secalis, Avenæ, Agrostidis, Phlei-pratensis) are now recorded for Scotland. The obligate relation of the fungus to the barberry plant is also confirmed. Mr. Dowson describes an interesting core-rot and premature fall of apples associated with the fungus *Sclerotinia fructigena*, and Mrs. Alcock discusses the important and somewhat neglected phenomenon of successional disease in plants. She shows clearly how *Cryptomyces maximus*, which is a parasite, weakens *Salix fragilis* so that *Scleroderris fuliginosum*, a semi-parasite, can attack it. This in turn so weakens the tree that such a fungus as *Myxosporium scutellatum*, which is mostly a saprophyte, can then invade the tissues.

This issue of the Transactions opens with a fine portrait of Mr. Cheeseman, the president elect of the Society in 1926. Mr. Cheeseman was the type of amateur field-naturalist to which botanical science in England owes so much. Such men are now, unfortunately, all too rare, and Mr. Cheeseman's untimely death removes one who can little be spared in mycology. Many of us will remember him, in addition, as a very fine type of English gentleman. W. B. B.

Forest Administration in British Honduras.

BEFORE the War, forestry administration in many British smaller colonies and dependencies remained a dead letter. The governors were either men trained to diplomacy or distinguished soldiers. If consideration was given to the matter, it was dismissed with the argument that forestry would not pay. That the argument was fallacious can already be demonstrated by practical examples. For many years British Honduras has been noted for its mahogany, which was extracted on the principles that have destroyed so many forests in the world. Four years ago, the first attempt at introducing a forest administration into the country was made—not without many doubts as to the wisdom of the projected step, both at home and in the colony. A two years' trial was to be made, and three Forest Officers were appointed.

The fourth annual forest report on this new departure has just been issued. From its pages it is easy to see that the young department has already made good. So far, the work has been mainly devoted to assisting the several lumbering companies at work in the forests on government leases. In some respects the operations are proceeding on lines similar to the working of the Burmese forests by the British forest officers of earlier days. Already, however, the work of exploring the government forests, collecting topographical and other details, has been commenced (the superior staff now amounting to six), and it is hoped to be able to carry out the exploration of the practically unknown territory of the Western Highlands. The following remark in the report illustrates how fascinating and valuable this work will prove:

"At the time of writing a reliable base-line has been established between Vaca and the Rio Grande and a good general idea of the forests of this region obtained. The investigation has brought to light the presence of tree species hitherto unknown to occur in the Colony, and types of forest which, though mentioned in the narrative of Fowler and Sapper, have never been closely studied or described." The small staff have already commenced to study the sylviculture of some of the more important species such as mahogany and sapodilla, both at the successful and promising Botanic Station and elsewhere.

It may come as a surprise to many to realise that the forest produce of British Honduras is exported to the United Kingdom, Canada, and Bermuda, in the British Empire, and to the United States, France, Guatemala, Honduras, and Mexico. "The indications," says the Conservator of Forests, "of a developing trade in forest produce with Canada in the form of mahogany lumber, and with the neighbouring republics in the form of pine lumber, are satisfactory features. The general swing of the pendulum from foreign to British markets is governed by movements in mahogany: one would like to regard it as a permanent gain for British trade, but this would not be justifiable." It seems almost incredible that in view of the fact that four-fifths of the Colony's wealth is derived from its forests, the forest officer was only introduced four years ago, and that opposition should still exist to expenditure on the proper conservation and management of the forests; for this work, to be successful, will require a far larger staff than at present exists.

In the interests of the Empire it would be of value if the leaders responsible for the coal strike would give consideration to the following remark in the report: "The effects of the Coal Strike are at least in part responsible for a set-back in the price of mahogany." The report displays unmistakably the great possibilities of development in front of this Colony. The Conservator's attention may be directed to the oft-reiterated suggestion that vernacular names of trees, without their scientific ones, and also local vernacular terms untranslated, detract from the value of such reports outside the Colonies for which they are written.

University and Educational Intelligence.

Cambridge.—The late Prof. E. G. Browne has bequeathed to the University the sum of £2000 for the promotion of the study of the languages, literature, history, and religion of the Arabs, Persians, Turks, or other cognate Asiatic peoples.

The Gordon Wigan Prize for research in chemistry has been awarded to W. A. Waters, Gonville and Caius College, for an investigation on "Substitution in the Diphenyl Series." E. J. H. Corner, Sidney Sussex College, has been nominated to occupy the University table at the laboratory of the Marine Biological Association at Plymouth in March next.

Proposed regulations for the new professorship in political science have been published. Amongst points of interest are the proposals that the professor shall be excused residence in the University for one term in each year, if his absence is for the purpose of studying the working of political institutions or the development of political theory, and that grants may be made from the income of the endowment of the chair to the professor towards his travelling expenses or to students for purposes of travel or research.

Edinburgh.—Dr. F. G. Banting, professor of medical research in the University of Toronto, has been awarded the Cameron Prize in recognition of his investigations on insulin and on the treatment of diabetes. This prize, which was founded in 1878, "may be awarded annually to a person who, in the course of the five years immediately preceding, has made a highly important and valuable addition to Practical Therapeutics."

London.—The title of professor of psychology in the University has been conferred on Dr. Beatrice Edgell, in respect of the post held by her at Bedford College. The title of reader in psychology was conferred on her in Feb. 1913. She is the author of "Theories of Memory" (1924), "Mental Life" (1926), and numerous papers in the *Proceedings of the Aristotelian Society*, *Mind*, and similar publications.

Three further courses of free public lectures are announced, namely, "Allergic Diseases caused by Factors of Climate," by Prof. W. Storm van Leeuwen (University of Leyden), at the Sherrington School of Physiology, St. Thomas's Hospital, at 5 o'clock on Feb. 14, 15, and 16; "The Ostracoderms, their Organisation and Relationships," by Prof. E. A. Stensio (of the Royal State Museum of Natural History, Stockholm), at University College, at 5.30 on Feb. 17, 18, 22, and 24; "Trigonometrical Series," by Prof. G. H. Hardy, at the Imperial College of Science and Technology, at 5.30 on Feb. 17, 24, and Mar. 3.

Oxford.—The first professors of Oxford to receive the title 'emeritus' under a new statute are two former occupants of the Linacre and Sherardian chairs Dr. Gilbert Bourne and Dr. Sydney Vines. The qualification is an automatic and a curious one, namely, "at least 15 years' service as professor." Under this clause of the new statute, Dr. Bourne's great predecessor, Sir Ray Lankester, would appear not to be eligible for the new title, whereas nearly one-half of Oxford's professors of botany are easily, if posthumously, emeritus, their years of service having been: Bobart, 36 years; Humphrey Sibthorp, 37 years; Williams, 38 years; Daubeny, 33 years; Vines, 31 years.

In the Regulations for the Memorial Prize founded in memory of Prof. Rolleston and open to members of the Universities of Oxford and Cambridge, the title of the subject has been redefined as for zoology and comparative anatomy instead of for human and comparative anatomy.

Tate scholarships at the Battersea Polytechnic in engineering, science, and domestic science, ranging in value from £20 to £30 a year, with free tuition and tenable for three years, will shortly be awarded. The examinations for the scholarships will begin on June 14. The latest date of entry is April 23.

The Sir John Cass Technical Institute, Jewry Street, Aldgate, London, E.C.3, is celebrating its twenty-fifth anniversary on Feb. 21, when the Institute will be open for inspection. A number of exhibits and demonstrations has been arranged in the laboratories by students and by manufacturers of scientific and other apparatus.

Ranging from Feb. 21 to April 1 inclusive, a series of twelve free public Swiney lectures on geology will be given by Dr. W. T. Gordon in the lecture theatre of the Imperial College of Science, South Kensington, under the title of "The Origin and Structure of Rocks." The lectures will be delivered at 5.30 on Mondays and Fridays. No tickets will be required.

The Council of the Royal Statistical Society will this year award the Frances Wood Memorial Prize, value £30, for the best investigation, on statistical lines, of any problem affecting the economic or social conditions of the wage-earning classes. Particulars can be obtained from the honorary secretaries of the Society, 9 Adelphi Terrace, W.C.2, not later than Oct. 31.

The University of London Animal Welfare Society, which has been formed to arouse interest in the welfare of animals among university students and teachers, has arranged a series of four public lectures by Major R. F. Wall on the care of domestic animals. The lectures are being delivered at Birkbeck College, London, on Feb. 9, 16, and 23, and Mar. 2, at 5.45 P.M. On Feb. 25, at 5.30 P.M., a discussion on the humane slaughtering of animals will be opened by Prof. G. H. Wooldridge, at King's College. By the rules of the Society it is precluded from taking part in controversies relating to vivisection. The honorary secretary is Capt. C. W. Hume, 14 The Hawthorns, Finchley, London, N.3.

The West of Scotland Agricultural College annual report for 1925–26 records an increase in enrolment in central classes at Glasgow from 265 to 334, while the number of students in central classes at Kilmarnock (chiefly dairy and poultry schools) decreased from 292 to 277. The extension work included lectures and demonstrations with 35,661 attendances and 11,297 visits to farms, etc., by members of the College staff. Attention is directed to an important bequest by Mr. Colin Thomson for research work in connexion with the College and, in particular, with its dairy school at Kilmarnock. A first allocation proposed to be assigned under the bequest by the trustees amounted to £20,000, which is as much as two-thirds of the annual income of the College. A list of appointments gained by students during the year includes several in distant parts of the Empire: Canada, British West Indies, East and West Africa, the Sudan, the Federated Malay States, and Hong Kong. The report of the North of Scotland College of Agriculture records an attendance of 72 students at central classes, while extension work included lectures and demonstrations with 45,557 attendances, 14,135 visits to farms, etc., and 34,735 attendances at systematic and continuation classes.

Calendar of Discovery and Invention.

February 14, 1748.—The two great discoveries of Bradley were those of aberration and nutation. Both resulted from his attempt to determine the parallax of the stars. Aberration was discovered in 1727; he recognised nutation twenty years later, his discovery being made known in a letter dated Feb. 14, 1748, addressed to the Earl of Macclesfield. Bradley at that time was Astronomer-Royal, having succeeded Halley in 1742.

February 14, 1876.—In his attempts to transmit musical sounds by electricity, Alexander Graham Bell in 1875 devised a harmonic telegraph, in which reeds at the receiving end were set in motion by electro-magnets. It was an irregularity in the working of this which led Bell to the invention of the telephone. Elisha Gray had also been working at a telephone, and on Feb. 14, 1876, both filed applications for patents with the American Patent Office. It was found, however, that Bell's application had been received first, and a patent was granted him.

February 15, 1615.—Among the early works of interest to the engineer is "Les Raisons des forces mouvantes avec diverses machines . . ." of Salomon de Caus, the French architect. The author dedicated his work to Louis XI. on Feb. 15, 1615. It is in this work that he enunciated the theorem of the expansion and condensation of steam and his application of steam for raising water.

February 16, 1889.—Formally opened in March 1851, Owens College, Manchester, was referred to in 1858 by the *Manchester Guardian* as "a mortifying failure." Its later success was largely due to Roscoe, who had been appointed to the chair of chemistry in 1857. Thirty years later he retired, and in an address dated Feb. 16, 1889, presented to him by his former students, it was said: "For upwards of thirty years you have had the control and direction of the chemical department of the Owens College. You leave it the best-organised and best-equipped school of chemistry in the kingdom, numbering its students by hundreds, and the acknowledged model of the many similar institutions which the success of your own school has called into existence." Roscoe, like Playfair in after life, entered Parliament and was one of the recognised spokesmen for science in Great Britain.

February 17, 1753.—Stephen Gray, a pensioner of the Charterhouse, Dufay, a French military officer, the Abbé Nollet, and Sir William Watson, all transmitted electricity along wires, but the earliest distinct proposal for an electric telegraph is that contained in a letter signed "C. M." in the *Scots Magazine* for Feb. 17, 1753. By some "C. M." is believed to stand for Charles Morrison; by others for Charles Marshall; both of whom lived at Renfrew. The suggested telegraph had an insulated wire for each symbol; the receiver noted the attraction by a ball attached to the wire of a strip of paper about ⅛ inch below it, on which was the symbol.

February 19, 1878.—During the summer of 1877, while engaged in the invention of a telegraph repeater for increasing the speed of sending telegrams, Edison used a metal disc with paper on it on which an embossing point worked by an electro-magnet indented dots and dashes. By reversing the operations and revolving the disc rapidly, musical notes were obtained. This suggested to Edison a means of recording and reproducing the sounds of the human voice, the first sketch of the phonograph being made on Aug. 12, 1877, and a patent being obtained on Feb. 19, 1878. E. C. S.

Societies and Academies.

LONDON.

Royal Society, Feb. 3.—**W. A. Bone, R. P. Fraser**, and **D. A. Winter**: The initial stages of gaseous explosions. Part 1—Flame speeds during the initial 'uniform movement.' A gaseous explosive mixture is ignited at the *open* end of a horizontal tube 2·5 cm. in diameter. So long as the initial flame speed does not exceed about 4000 cm. per sec., there is a definite initial 'uniform movement,' the speed of which, under standard conditions of experiment, was nearly always fairly constant. But with initial flame speeds exceeding such limits, in ethylene-oxygen and acetylene-oxygen mixtures, the flame speed was continuously accelerated *ab initio* until detonation is set up, just as though the explosive mixture had been fired near the *closed* end of the tube. In hydrogen-oxygen mixtures, whilst the uniformity of the initial movement was still maintained, its speed tended to vary. In certain circumstances, a slow 'uniform movement' of flame can be developed in an explosive mixture after an initial period of continuous acceleration. Thus the speed at which a slow uniform flame movement can travel through an explosive mixture cannot be regarded as a physical constant of it, in the same sense as its rate of explosion (that is, detonation).

W. A. Bone, R. P. Fraser, and **D. A. Winter**: The initial stages of gaseous explosions. Part 2—An examination of the supposed law of flame speeds. The mixtures used for the tests have included several complex hydrocarbon and hydrogen-oxygen mixtures, in which the hydrocarbon has been either acetylene, ethylene, or methane; also a series of complex methane-hydrogen-air mixtures, all containing excess of combustible gas, have been examined. When ethylene, or methane was the hydrocarbon used, and the primary mixtures both contained excess of combustible gas, the effect of successive additions of the primary hydrogen-oxygen mixture to the primary hydrocarbon-oxygen mixture (both having the same initial uniform flame speed) is progressively to depress the initial uniform flame speed of the resulting complex mixture, until it refuses any longer to propagate flame. It therefore follows that Payman and Wheeler's 'law of flame speeds' is not generally applicable to gaseous explosions.

A. Egerton and **S. F. Gates**: On detonation of gaseous mixtures of acetylene and of pentane (1). The conditions for detonation to occur in the same place in a tube of certain dimensions have been investigated for acetylene and for pentane mixtures of definite composition. Detonation appears to take place slightly ahead of the combustion front. The 'anti-knock' compounds, lead tetraethyl and diethylselenide, did not affect the position of detonation at ordinary initial pressures and temperatures.

A. Egerton and **S. F. Gates**: On detonation of gaseous mixtures at high initial pressures and temperatures (2). Detonation in acetylene and in pentane mixtures at high initial temperatures (230° C.) and pressures (10 atmospheres) has been investigated photographically, using a steel tube fitted with glass windows. Increase of initial pressure engenders earlier detonation up to a certain limit, when further increase makes very little difference. At a given initial pressure, rise of initial temperature appears to render detonation slightly later. Lead tetraethyl does not affect the position of detonation at high pressure either at normal initial temperature or at 23° C.

W. A. Bone and **A. Forshaw**: Studies upon catalytic combustion. Part 5.—The union of carbonic oxide and other gases with oxygen in contact with a fireclay surface at 500° C. The surface catalyses the combination of (moist) carbonic oxide and oxygen much in the same way as it does that of hydrogen and oxygen at the same temperature, though in a less degree. With a moist mixture of the carbonic oxide and oxygen in their combining proportions, the rate of combination is always directly proportional to the pressure of the dry mixture, provided that the surface is in a 'normal' condition, and the reaction product quickly removed from the system. The catalysing power of the surface can be greatly stimulated, but not permanently, by previous exposure at the reaction temperature to the combustible gas. When the carbonic oxide and oxygen are present in other than their combining proportions, their rate of combination is proportional to the partial pressure of the carbonic oxide. Of hydrogen, carbonic oxide, and methane, the first-named is the most, and the last-named the least, amenable to the catalytic combustion.

M. W. Garrett: Experiments to test the possibility of transmutation by electronic bombardment. An attempt to transmute tin into indium, in a quartz apparatus similar to that used by Smits, proved a failure, in spite of the employment of high current densities and the extraordinary sensitiveness of the spectroscopic method. Indium was detected in all the samples of 'pure' tin examined. The 4102 line was found to be the most persistent in the spectrum of this element (de Gramont lists 4511). Attempts were made to prepare scandium from titanium, using electrons of sufficient speed to be certain of penetrating the *K* ring of this element. Titanium was bombarded with 12,000-volt electrons from a hot filament in an evacuated bulb, but no evidence of any transmutation was obtained.

R. G. J. Fraser: The effective cross-section of the oriented hydrogen atom. Search for a change in the collision area of the hydrogen atom following space quantisation yields a negative result. The hydrogen atom in the normal (1*s*) state is thus isotropic. Spherical symmetry for an *s*-state follows as a necessary consequence of the Schrodinger atom theory; hence the present result, and also the absence of double refraction in space quantised sodium vapour (Schütz), are satisfactorily explained.

L. Pauling: The theoretical prediction of the physical properties of many electron atoms and ions: Mole refraction, diamagnetic susceptibility, and extension in space. The general method followed is capable of refinements which should make possible the accurate prediction of the properties of any atom or ion. The most obvious one is the use of the wave mechanics in determining the state of an electron under the influence of a positive nucleus and several idealised electron shells. Explicit expressions for the properties of an electron in such a state may then be derived, eliminating the necessity of the more or less inaccurate adaptation of the equations obtained for hydrogen-like atoms. Further progress may also be made in approximating an electron shell more closely than is possible with a spherical surface charge. All of these refinements will greatly complicate the treatment.

B. F. J. Schonland and J. Craib: The electric fields of South African thunderstorms. A station for measurements in electrical meteorology has been established at Somerset East, Cape Province, South Africa. Observations have been made of the electric fields and field changes associated with 18 distant and 5 near thunderstorms. The sudden changes of field due to distant lightning discharges (>8 km.) were predominately negative in sign, those due to near discharges (<6 km.) predominately positive. The relative frequencies of positive and negative changes were 1 : 5 in the former case and 4·3 : 1 in the latter. The steady electric fields below the five near storms were all strongly negative. These results indicate that the thunderclouds were bipolar in nature and that the polarity was generally, if not always, positive, the upper pole being positive and the lower pole negative. It is doubtful if any active storms of opposite polarity were observed at all. The mean value of the electric moments of the charges removed by 82 lightning discharges is 94 coulomb-kilometres.

Royal Microscopical Society, Dec. 15.—**Stanley Hirst**: Note on the development of *Allothrombium fuliginosum* Hermann. The six post-embryonal stages are: (1) ovum; (2) prelarval stage; (3) larval form; (4) resting stage of larval form; (5) nymph; (6) adult. The insects are parasitic on aphids both in the immature and adult stages. The adults suck the juices generally of the inert stages of the aphis. They also feed on freshly-killed flies and their maggots. Two species of aphids, *Macrosiphum gei* Koch. and *Myzus persicae* Sulzer, both occurring on the common dock, were used as food for both larval and adult *A. fuliginosum*.—**A. Kefalas**: A method of staining sections in acetone. Two staining solutions are used: (1) Liq. ferri sesquichlor (double B.P. strength), 3 c.c.; pure strong hydrochloric acid, 1 drop; 1 per cent. solution of ripe hæmatoxylin in good acetone, 100 c.c.; (2) is a saturated solution of Biebrich scarlet (Grübler) in acetone. The slides are passed through six stoppered cylinders of the old type containing xylol, acetone, solution (1), solution (2), acetone, and xylol. In solution (1) they are allowed to over-stain slightly. They are mounted in balsam. The method is cheap, rapid, and easy, well suited for routine work, and over-staining does not easily occur. The slides, moreover, are kept in a fixative solution all the time and are subjected to little change in osmotic tensions.—**J. Ramsbottom and E. H. Ellis**: Seedling structure of cultivated orchids. Fungal mycelium occurs in the roots of orchids, and in order to germinate the seeds, they must generally be infected by the same fungus. Germination can also be brought about by sterilising the seeds and supplying them with a nutrient solution containing some kind of sugar. Photomicrographs of numerous orchid seedlings and mature roots, the roots being of native British plants growing wild and of horticultural varieties, were examined. The seedlings showed fungal infection, distribution of the fungus, and 'clumping' of hyphæ in closely parallel series. Some of these seedlings (bi-generic hybrids, etc.) had been artificially inoculated by using cultures of one of the orchid fungi, whereas others had become infected when grown in the ordinary horticultural way. Seedlings of wild British orchids show the same sequence of events, and as the fungus is always the same for one species of orchid, it would appear that the process is an adaptative one and not merely chance parasitism.

Linnean Society, Jan. 6.—**C. Norman**: Pimpinellas of tropical Africa. This Umbelliferous genus is well represented in tropical Africa by about 25 species. It occurs in all parts of the tropical region, usually in open country at an elevation of not less than about 3000 ft., ascending to 10,000 ft. on the mountains. With one exception all the species belong to the subgenus Eu-pimpinella, and they are nearly always found growing amongst grasses in open country. Only one species seems to occur in tropical and southern Africa, and that is the common *P. caffra*, which reappears unexpectedly in Abyssinia.

Mineralogical Society, Jan. 18.—**A. Brammall and H. F. Harwood**: The temperature-range of formation for tourmaline, rutile, brookite, and anatase in the

Dartmoor granite. Applying Wright and Larsen's conclusions concerning rock types in which quartz originated in the *a*- or the *β*-phase, the authors adduce petrological evidence to support the following approximations: The range for tourmaline extends from magma-temperatures *circa* 800° downwards through an optimum range *circa* 600°-300° into an unfavourable range with an undetermined lower limit. The range for rutile is at least co-extensive with that for tourmaline. The range for anatase extends downwards from temperatures connoted by crystallisations from small residual pools of borosilicate flux accumulating at a late stage in the consolidation of the granite ground mass, to temperatures at which simple hydrolysis of biotite occurs. The range for brookite lies within that for anatase. For each species, extension of the range downwards may be necessary to cover cases of suspected authigenic growth in sediments.—**A. Russell**: Notice of an occurrence of niccolite and ullmannite at the Settlingstones Mine, Fourstones, Northumberland; of stichtite at the Island of Unst, Shetlands; and of serpierite at Ross Island Mine, Killarney, Co. Kerry, Ireland. In working a body of galena in the witherite vein of Settlingstones mine, a small quantity of very rich niccolite intimately associated with ullmannite, blende, galena, and witherite, was met with. Polished sections of the ore show the niccolite in roughly spherical to botryoidal forms, often surrounded by fringes of ullmannite and associated with brown blende and white witherite. Minute cubes of ullmannite occur in the witherite. Stichtite occurs in characteristic fibrous lilac-coloured specimens associated with kämmererite and chromite in serpentine at the "Kämmererite Quarry," Nikka Vord, Balta Sound, Island of Unst, Shetlands. The rare mineral serpierite occurs in cavities in cellular calamine ($ZnCO_3$) on the old dumps at Ross Island Mine, Killarney, Co. Kerry, Ireland. It forms small greenish-blue spherical aggregates composed of minute crystals flattened parallel to *c*(001) and elongated in the direction of the *a* axis.

Geological Society, Jan. 19.—**L. J. Chubb**: The geology of the Austral or Tubuai Islands (Southern Pacific). This group is situated about 350 miles south of Tahiti, and 1800 miles north-east of New Zealand. It includes seven islands, of which four are here described. Rapa is a crateriform island, the slopes of which have been deeply dissected by radial streams, while the ends of the spurs between the valleys have been strongly cliffed by the sea. After one of the radial streams had captured the drainage of the crater, the island was submerged, with the result that the river-valleys were embayed, and the crater flooded. Afterwards slight elevation occurred. Marotiri consists of a number of needle-like stacks rising out of the sea, and situated roughly on the circumference of a circle. Probably it represents the last stage of an island of the type of Rapa which has subsided. Rurutu is without the sharp peaks and serrated ridges characteristic of Rapa, and the valley-mouths are not embayed. The history of the island appears to be one of frequently-renewed, intermittent elevation, stationary periods being indicated by raised plateaux, and the different degrees of weathering of the rocks at different levels. In the later stages a fringing-reef came into existence, which was finally uplifted. A narrow fringing-reef has developed around the island in recent time. Rimatara is surrounded by a coral-reef about 2 miles wide. The outer edge of the central island is occupied by an elevated reef, which faces the sea in a line of cliffs 20 or 30 feet high. The islands are arranged along lines having a general west-north-westerly and east-south-easterly trend; their movements of elevation and subsidence may be due to their being situated on a submerged anticlinal fold, the crest of which has moved northwards.—**W. Campbell Smith** and **L. J. Chubb**: The petrography of the Austral or Tubuai Islands (South Pacific), with chemical analyses by **E. D. Mountain**. Except for a few small local occurrences of pyroclastic rocks, the volcanic rocks of Rapa consist of phonolitic and basaltic lavas invaded by many dykes and other small intrusions. Of the latter, the most interesting probably forms the plug in the vent of the main volcano. It is an extremely melanocratic olivine-theralite. The basic porphyritic basalts are the predominant lavas: they resemble the picritic basalts of Hawaii and the ankaramites (ultrabasic basalts) of Tahiti. All the acid and basic lavas compare very closely with rocks from Tahiti, while rocks comparable with the trachybasalt and the basic andesine-andesite have been described from Hawaii. In Rurutu occurs an olivine-bearing nepheline-tephrite, which resembles a rock described from Franklin Island (Antarctica). Otherwise the basic lavas found in this island are similar to those of Rapa.

EDINBURGH.

Royal Physical Society, Jan. 17.—**A. C. Stephen**: A short list of mollusca collected off Franz Joseph Land and Spitsbergen by the British (Algarson) Arctic Expedition, 1925.—**A. W. Greenwood**: Pterylosis in the 'hackleless' fowl. A study of the distribution and development of plumage in the 'hackleless' fowl does not support the view that this is an example of the inheritance of an acquired pathological condition. The condition appears to be genetic in origin and is due to the complete absence of feather follicles in certain areas of the body.—**Miss J. S. S. Blyth**: The Manoilov reaction for the identification of sex and its application to the case of the sexually abnormal fowl. It can be shown that the Manoilov test is not an all-or-none reaction but a quantitative one. The intersexual individual gives a reaction intermediate between that of the normal male and the normal female, and varying with the degree and type of sexual abnormality.

MANCHESTER.

Literary and Philosophical Society, Jan. 11.—**W. H. Lang** and **Isabel C. Cookson**: Some early palæozoic plants from Victoria, with comparative remarks. These specimens have been brought from the collections of the Geological Survey of Victoria and the National Museum, Melbourne, for comparison with British pre-carboniferous plants. They were found in rocks of the Wallhalla syncline in the Gippsland region that are usually regarded as of Yeringian (Upper Silurian) Age. On palæontological grounds the chief plant-containing beds are, however, believed by Mr. F. Chapman to belong to a higher series, which he terms Tanjilian; the Geological Survey on stratigraphical grounds places these beds at a lower level in the Yeringian. While the geological age of the beds must largely depend on their animal fossils, it has been rightly pointed out by Chapman that the plant-remains would support an age considerably later than the Silurian. They include stems of uncertain affinity with crowded, long, simple leaves; shoots with small leaves or spines which have been described and figured as Arthrostigma, but appear more closely comparable with the Middle Devonian plant Thursophyton; smooth-branched axes that resemble those from the Middle Devonian which are known as *Hostimella sp.*, and sometimes even agree with these in the presence of a 'bud-like' structure in the axil of the branch; and fragments that may be of such plants, though the possibility of the occurrence of Nematophyton must be kept in mind. The flora, as represented by these specimens, on the whole suggests comparison with that of the Middle Devonian or Middle Old Red Sandstone of the northern hemisphere. Its occurrence in rocks along with a Silurian fauna raises interesting problems.—**E. J. Williams**: The passage of α- and β-particles through matter. Experimental results for the number of ions per unit length of track produced by β-rays (velocity about 5×10^9 cm./sec.) in hydrogen, nitrogen, and oxygen are given. The theoretical values, according to Sir J. J. Thomson's theory, account for only about one-half of the observed ionisation. New calculations are given in which the motion of the atomic electrons is taken into account. The necessary data for the calculation of the theoretical values are most certain for hydrogen, and in this case the new theoretical value is within experimental error of the observed value. In discussing stopping powers, values for β-rays recently obtained by Mr. Nuttall and the author are used. These are free from errors arising from scattering. The relation between the atomic stopping powers for α-rays and those for β-rays are discussed. Bohr's theory does not represent the facts. Allowance for the motion of the atomic electrons decreases the discrepancy between Henderson's theory and the observations, about 80 per cent. of the stopping power being thus accounted for. The residual discrepancy is probably real and it may be greater for α-rays than for β-rays.

Paris.

Academy of Sciences, Jan. 4.—**Gaston Julia**: The means of the moduli of analytical functions.—**Jean Thibaud**: The various crystalline forms of long-chain organic compounds and the difficulties of interpretation of their X-ray spectra. The interstice *d* of an organic substance capable of orientation, taken as an analytical character, is subject to variation, depending on its origin, mode of preparation, and its degree of purity. When the substance to be analysed is a mixture of similar substances with nearly the same number of carbon atoms in the molecules, the use of the interstice loses part of its analytical value.—**A. Henne** and **G. L. Clark**: The spectrography of flames in an explosion motor. Photographs were taken of the complete explosion and also of the four quarters of the explosion separately, with special reference to the phenomenon of knocking. The influence of the addition of such antidetonants as lead tetra-ethyl is to regularise the explosion in such a manner that the amount of energy liberated per unit of time varies only slightly throughout the course of the explosion.—**Nicolas Perrakis**: The specific heats of a sufficiently cooled non condensed phase. J. Perrin, from Eucken's experiments, arrived at the conclusion that all gases sufficiently cooled take the same molecular heat as the monatomic gases. The same conclusion is now obtained from simple theoretical considerations.—**Mme. Ramart-Lucas** and **Mlle. Amagat**: Molecular transpositions. The preparation and dehydration of some α-alkyl-α-phenylethanols.—**G. Darzens** and **A. Heinz**: *p*-Xylylallylacetic acid and its conversion into cyclic tetrahydronaphthalene derivatives. The preparation of a new dimethyl-naphthalene. This synthesis is carried out in the following stages: ethyl *p*-xylylmalonate, ethyl *p*-xylyl-allyl-malonate, dimethyltetrahydronaphthalene carboxylic acid, dimethylnaphthalene carboxylic acid, dimethyl-naphthalene.—**Itizo Kasiwagi**: The action of nitromethane and its homologues on benzil.—**G. Kempp**: The modification of a frequency curve brought about by the superposition of a sinusoidal variation with accidental variability. A mathematical discussion of the temperature variations at Spitsbergen.—**Pierre Lesage**: The persistence of precocious character (in plants) at different periods of the year.—**Henri Humbert**: Two types of unifacial structure of the leaf in Madagascan Senecio.—**G. Guittonneau**: The microbial oxidation of sulphur in the course of ammonia production from peptone.—**J. Sabrazes**: The spirochæte of yaws (*Spirochæta pertenuis*): its coloration.

Copenhagen.

Royal Danish Academy of Science and Letters, Nov. 11.—**O. B. Bøggild**: The meteoric iron block from Savik at Cape York. Occurrence and history; form and surface; composition of the interior; researches of the structure of the octahedrites.

Dec. 17.—**Niels Bohr**: Atomic theory and wave mechanics. The quantum theory of atomic constitution contains an essential element of discontinuity contrasting with the classical theories of mechanics and electrodynamics. In view of the recent promising results of the modification of classical mechanics known as the wave mechanics, the problem has arisen as to the possibility of avoiding any element of discontinuity in the description of atoms. This possibility, however, would seem excluded in the present state of science, where we meet with difficulties regarding fundamental concepts common for the classical theories and wave mechanics.

Geneva.

Physical and Natural History Society, Dec. 16.—**E. Briner**, **G. Lunge**, and **A. Mirimanoff**: The reaction of nitrogen peroxide with sulphurous anhydride. The reaction is $2SO_2 + 3NO_2 = S_2N_2O_9 + NO$. The substance $S_2N_2O_9$ was obtained by La Provostaye, who, however, supposed it to be formed by another process.—**E. Briner** and **O. Agathon**: On the combinations of the phenols with ammonia, and the formation of higher ammoniates. Besides the monoammoniates formed by the addition of one molecule of ammonia to the phenols, the authors found, in operating with higher pressures, a production of ammoniates containing several molecules of ammonia.—**A. Jayet**: The Albian of the Reposoir (Haute-Savoie).—**L. W. Collet** and **R. Perret**: A supplement to the geology of the Col d'Anterne and the Cirque des Fonts.—**E. Bujard**: Action of repeated injections of ovalbumin upon the testicle of the white rat. Lesions are produced similar to those produced by alcohol and iodine.—**E. Cherbuliez** and **R. Wahl**: The hydrofluoric hydrolysis of the proteids. This does not eliminate the formation of humic substances any more than does hydrochloric or sulphuric hydrolysis.—**A. Pictet**: Synthesis of lactose. Glucose is transformed into glucosane, and this into diglucosane. The latter is condensed with β-galactose, giving a lactose anhydride, which is then hydrolysed.—**E. Paréjas**: Bone deposit of the Doldenhorn. The fragments can be with certainty ascribed to a reptile.—**E. Paréjas**: New observations on the base of Mont Joly (Haute-Savoie). A correction of tectonic interpretation; the coal strata are triassic and not carboniferous.

Sydney.

Linnean Society of New South Wales, Nov. 24.—**Miss Lesley D. Hall**: The physiography and geography of the Hawkesbury River between Windsor and Wiseman's Ferry. A detailed description is given of the physiography of the main river and the lower portions of its tributaries. Man's dependence on physiographic factors is traced from the beginnings of settlement to the present day.—G. H. Hardy: A reclassification of the Australian robberflies of the Cerdistus-Neoitamus complex (Diptera-Asilidæ). The status of several genera, for which no scheme of classification hitherto evolved has met with general acceptance, is discussed. The generic name Cerdistus is adopted for the group, and under it Neoitamus, Cerdistus, and Stilpnogaster are ranked as subgenera, each of which is well represented in Australia.—A. H. S. Lucas: Notes on Australian marine algæ. (iii.) The Australian species of the genus Nitophyllum. *N. erosum* extends on the west coast so far north as the Houtman's Abrolhos, and *N. sinuosum* up to Port Stephens on the east coast, but the genus is only abundantly represented in the south, with its headquarters in Bass Straits, where multifarious forms occur which may be regarded as varieties or species.—M. Aurousseau: Analyses of three Australian rocks. Analyses are presented (*a*) of the well-known rock from One Tree Point, Sandy Bay, Hobart, Tasmania, a supposed fayalite basalt or melilite basalt, but actually a nephelite basanite; (*b*) of a micrographic granite from Ashford, N.S.W., that shows complicated graphic intergrowth; (*c*) of a peculiar amphibolite from Bunker Bay, Cape Naturaliste, W.A.—G. H. Cunningham: Gasteromycetes of Australasia. (vi.) The genus Lycoperdon. A critical revision of the members of the genus in Australia and New Zealand.

Origin of Mankind: being a Catalogue of Books relating to Anthropology, Folklore, Ethnography, Archaeology, Occult, Heathenism, Witchcraft, Native Races, Mythology, Magic and sundry other Subjects concerning Man. (No. 491.) Pp. 68. (London: Francis Edwards.)

Neue Bücher. Januar. Pp. 47. (Berlin: Julius Springer)

Diary of Societies.

SATURDAY, February 12.

Royal Institution of Great Britain, at 3.—W. de la Mare: 'Atmosphere' in Fiction.

Mining Institute of Scotland (at Edinburgh)

MONDAY, February 14.

Royal College of Surgeons of England, at 4.—Sir Berkeley Moynihan, Bart.: Hunterian Oration.

Royal Irish Academy, at 4.15.

Royal Society of Edinburgh, at 4.30.—Dr R. T Gunther: Certain Early Astronomical Instruments and their Makers, illustrated by the Exhibition of Instruments in the possession of the University of St. Andrews and by lantern slides (Address).—Sir J. R Findlay: Exhibition and Description of certain Instruments from his Private Collection.

Royal Geographical Society (at Lowther Lodge), at 5.—Lt.-Comdr. R. Gould: The Landfall of Columbus.

Institution of Automobile Engineers (Birmingham Centre) (at Chamber of Commerce, Birmingham), at 7.—H. W. Sisman: The Straight-Eight Engine.

Institution of Electrical Engineers (North-Eastern Centre) (at Sopwith's Café, Newcastle-upon-Tyne), at 7.—Informal Discussion on The Problem of Rural Supplies.

Institution of Electrical Engineers (Western Centre) (at South Wales Institute of Engineers, Cardiff), at 7.—W. M. Selvey: Power Stations and their Equipment (Lecture).

Institute of Metals (Scottish Local Section) (at 39 Elmbank Crescent, Glasgow), at 7.30.—D. R. Tullis: Notes on Aluminium Alloys.

Aristotelian Society (at University of London Club), at 8.—Prof. R. F. A. Hoernle: Problems and Methods of Metaphysics.

Royal Society of Arts, at 8.—Prof. E. G. Coker: Photo-elastic Measurements of Stress Distribution (Cantor Lectures) (1).

Institute of Chemistry (Edinburgh and East of Scotland Section) (jointly with Society of Chemistry, Edinburgh and East of Scotland Section) (at 36 York Place, Edinburgh), at 8.—B. D. W. Luff: The Use of the Microscope in Qualitative Analysis.

British Psychological Society (Education Section) (at London Day Training College), at 6.—Dr. Cloudesley Brereton: The Philosophical Basis of the Teaching of Literary Appreciation.

Cambridge Philosophical Society (in Botany School, Cambridge), at 4.45.—Prof. H. L. Hawkins: Some Problems in the Evolution of the Echinoidea.

Institute of Chemistry (Manchester and District Section).—Prof. R. Robinson: Electronic Theories of Valency in Organic Chemistry.

TUESDAY, February 15.

Electrical Association for Women (at King's College for Women (Household and Social Science Department), Campden Hill Road), at 5.15.—Mrs. C. Frederick: How the American Housewife solves her Household Difficulties.

Royal Statistical Society (at Royal Society of Arts), at 5.15.—G. H. Wood: An Examination of some Statistics relating to the Wool Textile Industry.

Royal Society of Medicine, at 5.30.—General Meeting.

Royal Sanitary Institute, at 5.30.—Dr. W. Robertson and others: Discussion on Immunisation against Diphtheria.

Royal Aeronautical Society, at 6.—W. H. Dyson and others: Informal Discussion on Materials, with special reference to Corrosion.

Child-Study Society (at Caxton Hall), at 6.—Hon. Bertrand Russell: Nursery Schools

London Natural History Society (at Winchester House, E.C.), at 6.30.—H. Spooner: The Natural Regeneration of Woodlands.—R. W. Hale: The Little Owl.

Society of Chemical Industry (Glasgow Section) (jointly with Institution of the Rubber Industry) (at 39 Elmbank Crescent, Glasgow), at 7.—R. D. Porritt: The Milling of Rubber.—T. R. Dawson: The Hardness Testing of Vulcanised Rubber.—J. T. Strachan: Demonstration of a New Piezo-micrometer.

Royal Photographic Society of Great Britain, at 7.—J. C. Dollman: Good Taste, Bad Taste, and No Taste at all.

Institution of Automobile Engineers (Wolverhampton Centre) (at Engineering and Scientific Club, Birmingham), at 7.30.—A. H. R. Fedden: The Supercharging of Aircraft and Motor Vehicle Engines.

British Institute of Philosophical Studies.—Prof. J. S. Huxley and Dr. M. Ginsberg: The Claims of Eugenics.

WEDNESDAY, February 16.

Society of Glass Technology (jointly with Yorkshire Section of Society of Chemical Industry) (at Sheffield University), at 2.30.—General Discussion on Silicate Analysis:—W. H. Withey: A Critical Survey of Methods for the Analysis of the Simpler Glasses.—Violet Dimbleby: Notes on Methods Used in the Analysis of Glasses.—W. J. Rees: The Analysis of Refractories.—T. P. Colclough: Notes on the Analysis of Silicate Slags.

Royal Society of Medicine (History of Medicine Section), at 5.—Prof. J. F. Dobson: Erasistratus.—W. R. Dawson: Contribution to the History of Mummification.—Dr. C. Singer: An Example of the Egyptian God Bes Exhibiting Symptoms of Spina Bifida.

Royal College of Surgeons of England, at 5.—Prof. E. M. Cowell: Recent Advances in the Surgery of Hernia.

Royal Institution of Great Britain, at 5.15.—Prof. J. S. Huxley: Problems of Animal Growth and Development (3).

Institution of Civil Engineers (Students' Meeting), at 6.30.—R. F. Legget: Some Considerations of our Power Resources.

Institution of Automobile Engineers (Manchester Centre) (at Engineers' Club, Manchester), at 7.—E. W. Sisman: The Straight-Eight Engine.

Institution of Electrical Engineers (Mersey and North Wales (Liverpool) Centre) (jointly with Liverpool Engineering Society) (at The Temple, Dale Street, Liverpool), at 7.

Institution of Electrical Engineers (South Midland Centre) (at Birmingham University), at 7.—P. Dunsheath: 33,000-Volt Cables with Metal-Sheathed Cores, with special reference to the S. L. Type.

North-East Coast Institution of Engineers and Shipbuilders (Graduate Section) (at Bolbec Hall, Newcastle-upon-Tyne), at 7.15.—E. Hinchliffe: The Experiment Tank in Ship Design.

Institution of Electrical Engineers (Sheffield Sub-Centre) (jointly with Institute of Metals—Sheffield Local Section) (at Sheffield University), at 7.30.—Dr. V. E. Pullin: The Application of X-Rays to the Examination of Metals (Lecture).

Eugenics Society (at Hotel Rembrandt), at 7.30.—Dr. A. F. Tredgold: Mental Disorder in relation to Eugenics (Galton Lecture).

Merseyside Aquarium Society (at Liverpool Museum), at 7.30.

Royal Meteorological Society, at 7.30.—Dr. J. Glasspoole: The Variability of Average Monthly Rainfall throughout the Year.—Dr. L. F. Richardson and D. Proctor: Diffusion over Distances ranging from 3 km. to 86 km.

Royal Society of Arts, at 8.—C. C. Paterson: Some Studies in Electric Lamps and Valves.

Folk-Lore Society (Annual Meeting) (at University College), at 8.—Presidential Address.

Royal Microscopical Society, at 8.—Dr. W. E. Cooke: The Life History of the Neutrophil Polymorphonuclear Leucocyte.—Dr. A. S. Parkes, Dr. F. W. R. Brambell, and F. Melville: The Effect of X-Ray Sterilisation on the Development of the Accessory Organs of Reproduction in the Mouse.

Institute of Chemistry (London Section).

Royal Medico-Psychological Association (at Cheshire County Mental Hospital, Parkside, Macclesfield).—Prof. T. H. Pear: Recent Investigations on Visual Imagery, with special reference to Hallucinations.

THURSDAY, February 17.

Royal Society, at 4.30.—G. U. Yule: Wolfer's Sunspot Numbers considered as a Disturbed Periodic Series.—Dr. G. M. B. Dobson and D. N. Harrison: Measurements of Ozone in the Earth's Atmosphere and its Relations to other Geophysical Conditions—Part II.—H. Horrocks: Meteorological Perturbations of Tides and Currents in an Unlimited Channel Rotating with the Earth.—*To be read in title only:*—Prof. H. Levy and A. G. Forsdyke: The Stability of the Vortex System in the Rear of a Moving Body.—A. Fage: The Flow of Air and of an Inviscid Fluid around an Elliptic Cylinder and an Aerofoil of Infinite Span.

Royal Institution of Great Britain, at 5.15.—Sir William Bragg: Acoustical Problems treated by Lord Rayleigh (3): Bells.

Child-Study Society (at Royal Sanitary Institute), at 6.—S. Marks: The Educational Aspect of the Model Theatre.

Institution of Electrical Engineers, at 6.—F. H. Clough: The Stability of Large Power Systems.

Royal Aeronautical Society (at Royal Society of Arts), at 6.30.—Major R. H. Mayo: The Design and Operation of Commercial Aircraft.

Chemical Society, at 8.—H. O. Askew: The Production of Fog in the Neutralisation of Alkali with Hydrogen Halides.—F. H. McDowell: Constituents of Myoporum Laetum Forst. (The "Ngaio.") Part II. Hydrogenation of Ngaione and Ngaiol, and Dehydration of Ngaiol.

Royal Society of Tropical Medicine and Hygiene (at 11 Chandos Street, W.), at 8.15.—Lt.-Col. W. P. MacArthur: Old-Time Typhus in Britain.

Institution of Mechanical Engineers (Manchester Meeting).

Institution of the Rubber Industry (Manchester Section) (at Liverpool).—H. C. Young: Production Methods in a Rubber Factory.

FRIDAY, February 18.

Geological Society of London, at 3.—Annual General Meeting.

Royal Astronomical Society (Geophysical Discussion), at 5.—Dr. Vaughan Cornish: The Propulsion of Waves in Granular Material by Winds and Currents. Other speakers, Dr. T. E. Stanton, Dr. H. Jeffreys. Chairman, Sir Frank Dyson.

Royal College of Surgeons of England, at 5.—Prof. A. H. Southam: The Pathology and Treatment of the Retained Testis in Childhood.

Society of Chemical Industry (Liverpool Section) (at Liverpool University), at 6.—Col. Sir Frederick L. Nathan: Fuels for Internal Combustion Engines.

Institution of Mechanical Engineers, at 6.—Annual General Meeting.

Society of Chemical Industry (Glasgow Section) (at 39 Elmbank Crescent, Glasgow), at 7.—Fuel Lecture.

Electrical Association for Women (at E.L.M.A. Lighting Service Bureau, Strand), at 7.—Mrs. C. Frederick: Household Engineering and Efficiency Tests.

Photomicrographic Society (at 4 Fetter Lane), at 7.—Members' Evening.

Royal Photographic Society of Great Britain (Pictorial Group), at 7.—A. L. Eavestaff: The Graphic Eye and the Photographic Eye.

Junior Institution of Engineers, at 7.30.—L. Turner: Modern Concrete Construction: A Review of Recent Progress and Problems.

Royal Institution of Great Britain, at 9.—Sir Josiah C. Stamp: The Laws of Monetary Science.

SATURDAY, February 19.

North of England Institute of Mining and Mechanical Engineers, at 2.30.

Royal Institution of Great Britain, at 3.—W. de la Mare: The Supernatural in Fiction.

Oxford University Junior Scientific Club (Exhibition Meeting), at 8.15.

Physiological Society (at St. Thomas's Hospital).

PUBLIC LECTURES.

SATURDAY, February 12.

Horniman Museum (Forest Hill), at 3.30.—Miss M. Edith Durham: Some Old Montenegrin Customs.

SUNDAY, February 13.

Guildhouse (Eccleston Square), at 3.30.—N. C. Sen: Brahmo Somaj.

MONDAY, February 14.

London School of Economics, at 5.—Prof. P. Geyl: Dutch Society and Dutch Politics in Spinoza's Time.

St. Thomas's Hospital (Sherrington School of Physiology), at 5.—Prof. W. Storm van Leeuwen: Allergic Diseases caused by Factors of Climate. (Succeeding Lectures on February 15 and 16.)

King's College for Women (Household and Social Science Department), at 5.15.—Prof. J. Garstang: The Songs of Birds.

TUESDAY, February 15.

Bedford College for Women, at 5.15.—Sir Frank W. Dyson: Conceptions of the Cosmos from the Times of Copernicus to Galileo.

King's College, at 5.30.—C. E. M. Joad: Vitalism and Theory of Knowledge.

WEDNESDAY, February 16.

Birkbeck College, at 5.45.—Major R. F. Wall: The Care of Domestic Animals. (Succeeding Lectures on February 23 and March 2.)

THURSDAY, February 17.

Imperial College of Science and Technology, at 5.30.—Prof. G. H. Hardy: Trigonometrical Series. (Succeeding Lectures on February 24 and March 3.)

King's College, at 5.30.—Rev. Dr. W. R. Matthews: The Mind: Philosophy.

University College, at 5.30.—Dr. E. Deller: 'The University Idea' in the United States.—Prof. E. A. Stensiö: The Ostracoderms, their Organisation and Relationships. (Succeeding Lectures on February 18, 22, and 24.)

Northampton Polytechnic Institute, at 7.—R. Genders: Steel and its Thermal Treatment (6): Cast and Malleable Cast Iron.

SATURDAY, February 19.

Horniman Museum (Forest Hill), at 3.30.—Dr. W. T. Calman: The Shipworm, a Pest of the Seas.

SUNDAY, February 20.

Guildhouse (Eccleston Square), at 3.30.—C. Bailey: The Religious Experiences of Ancient Rome.

SATURDAY, FEBRUARY 19, 1927.

The Preservation of Nature.

PUBLIC opinion is inclined to look upon the scenery and great natural monuments of a country as of the order that lasts for aye, and to imagine that their survival through many millennia betokens an infinite future. It little realises that in this and other civilised countries, human progress is constantly nibbling at the works of Nature, and that greatly as the rate of consumption has grown in recent years, the threat will undoubtedly be magnified in the years to come. The need of water-supplies for the centres of population has altered lakes and swamped valleys; the demands of industry have changed rivers and harnessed waterfalls; the vast requirements of the modern metalling of roads are cutting into the 'everlasting' hills; and the desire for speedy transport has driven and threatened to drive bleak roads through some of the select scenery of the land.

With all this there has been, of course, immense economic gain, but there has also been loss. There has been a loss of beauty, a destruction of things of æsthetic and artistic appeal; and who knows what unconscious influence these may have [illegible] had upon the minds of men? But there has also been a loss to science, sometimes material, more often of those historic-sentimental records, which, linking the achievements of the past with present-day knowledge, stir the imagination and stimulate the broad view. The haunts of a dwindling native flora and fauna are being disturbed: the driving of a road (abetted by the importunities of collectors) banished the Artaxerxes butterfly from its first discovered site in the King's Park, Edinburgh, which had "stocked the cabinets of Europe." Just as in Italy the Barma Cave, the richest and most interesting of the Grimaldi caves, which have added so greatly to the knowledge of palæolithic man, has been exploited for building stone, so the M'Arthur Cave at Oban, the first recognised habitation of Azilian man and, until the discoveries of last summer, the oldest known human dwelling in Scotland, has been entirely quarried away. The historic rock on Blackford Hill within Edinburgh, on the smoothed surface of which Agassiz first detected indubitable traces of an ice age, is threatened by the road-metal excavations of Midlothian County Council, and similar operations in Haddingtonshire will eat into Traprain Law, the site of extensive Celtic settlements and of the discovery of a unique silver hoard belonging to an early century of our era.

Here is a clash between 'business' on one hand

and æsthetics and science on the other. Obviously so disintegrating a warfare ought to be stopped, but how? Not by a simple attitude of protest, for the claims of 'business' cannot be lightly brushed aside, and the county council 'steam-roller' has an effective way of overriding objections. A burst of local effort endeavours to meet each new aggression, and occasionally a treasure is saved. Stybarrow and Glencoin Woods in Ullswater have thus been rescued within the last few weeks, and the *Times* of Feb. 5 announced that negotiations were understood to have reached a successful issue "whereby the land on the west side of the Borrowdale road, from Peterfield to the entrance to Stable Hills Farm, will be saved from all possibility of being built on, and the uninterrupted view over Derwent Water into the famous 'jaws' of Borrowdale and across to Cat Bells will be preserved intact for all time." In both cases appeal is made for public subscriptions of considerable amounts, necessary if successful negotiations are to be converted into the full goal of permanent preservation.

More often, however, the 'steam-roller,' if checked at all, is only temporarily checked and soon returns to complete its work. A year or two ago the danger seemed to have been turned from Traprain Law, but now preparations for extensive quarrying on part of the hill are in full swing. On the whole, local effort is too little organised, too spasmodic, too late in getting into action, too lacking in persistence and in authority to deal efficiently with such emergencies.

The needs of industrial progress are clamant and cannot be gainsaid by a point-blank negative, but is there no room for compromise? Compromise implies give and take on both sides; what has the æsthetic and scientific side to bargain with? As the law of Britain stands, it has nothing; for though more than twenty years ago France passed its first law towards the protection of 'sites pittoresques,' in Great Britain public opinion remains the only support. The matter seems to rest upon the nature of property in land; does purchase or possession imply for the possessor an absolute right to deal anyhow with the land he possesses? We act as if possession held this absolute right, and as if only by special appeal or through special favour may the right be waived; but ideas are changing and have changed. The absolute right no longer holds in the great cities, where an owner may not build upon his land except in accordance with the interests of the community as expressed by the Dean of Guild Court or some similar body.

The time will come when a natural monumen whether its message be æsthetic, historic, scientific, will be reckoned of as much value a garage, and its preservation or destruction matter not for the individual but for the nation.

Other countries, recognising their value in th national life, have moved or are moving toward a general conservation of the natural sites an monuments of artistic, scientific, historic, an legendary interest. A vast body of evidence i this sense was submitted to the "Congrès inter national pour la Protection de la Nature" held i Paris in the summer of 1923, and appears i the "Rapports, vœux et réalisations" of th Congress published in 1925. In 1906 the *lo Beauquier*, which provided for the classification o picturesque sites, particularly forest areas, by special commission in each department, and for th safeguarding of these places, set the ball rolling i France. Since then various measures of preservation have been applied to the colonies of France b decrees of the colonial minister. In Switzerland Spain, Poland, Jugoslavia, Hungary, and Russi the movement is strongly supported. In Grea Britain spasmodic efforts have become crystallise in the Royal Society for the Promotion of Natur Reserves in the British Isles, and it has alread done good work. We trust, however, that the lac of faith in the efficacy of parliaments and governments as protectors of the beautiful and interesting expressed at the Paris conference by the president Viscount Ullswater, does not mean that this influential society will refrain from impressing upo the government of the day the desirability of safeguarding natural monuments, until parliamentar recognition gives a national sanction far mor effective than that of any private organisatio could be.

If, as we assume, a method of compromis between industrial needs and the demand for th picturesque or significant will ultimately replac the spasmodic and point-blank opposition of th present, who is to arrange the compromise? It must be a body with authority, with knowledge, and with sympathies broad enough to gain the confidence of both sides. Local authorities are already sufficiently burdened with duties, and their very proximity may be apt to obscure the broad view.

In France the Government appointed a special commission for the precise purpose, and this would seem to be the most satisfactory method. We need a Nature Monuments Commission, an advisory body attached to one of the great departments o

State, with the needful statutory backing. This body, with such local help as could be obtained, might draw up lists of Nature monuments and haunts of rare animals and plants deserving of preservation, but a chief function would be to receive from recognised local bodies complaints of threatened destruction, and to decide whether the particular needs of economic development were such as to demand the sacrifice of a national asset, or whether some adjustment might be arranged so that whole or part of the threatened natural monument might be preserved.

Until recent years the handiworks of prehistoric man and his successors existed in Great Britain unprotected from the elements or from the despoiler (except where private ownership bestirred itself), and, as a consequence, hundreds of stone circles of the bronze age and prehistoric sepulchral cairns, as well as buildings of Roman or later times, have been demolished and converted into stone dykes and insignificant barns, byres, and cottages. But the creation by government of an Ancient Monuments Commission has saved the situation, and invaluable work has been done by this body in scheduling and protecting the irreplaceable relics of the former inhabitants of Britain. Here is a precedent for the creation of a Nature Monuments Commission, and here in many ways is a model for its labours.

James Ritchie.

The Chemistry of Rhythmic Actions.

The Problem of Physico-Chemical Periodicity. By Dr. E. S. Hedges and Dr. J. E. Myers. Pp. 95+2 plates. (London: Edward Arnold and Co., 1926.) 7*s.* 6*d.* net.

The normal chemist is so well used to seeing his reagents pass away in a decently continuous fashion, that when he finds them attacking each other in a succession of recurrent spasms, he is a little apt to shy off. The thing is, perhaps, too nearly suggestive of heart-beats, of vital processes, and of human activities: domains into which chemists are warier of intruding than formerly, and which they prefer to leave to their bolder brethren, the physiologists and the historians. At all events, rhythmic, pulsating, or periodic reactions have seldom been systematically followed up in any general way by chemists. There have been, it is true, such detailed inquiries as Ostwald's on the periodic dissolution of a specimen of chromium in acid, as Bredig's on the pulsating decomposition of hydrogen peroxide by mercury, and as the numerous studies of the Liesegang effect in jellies; but Dr. Hedges and Dr. Myers have now worked their way to a more comprehensive survey than these, which they have summarised in a small monograph. The broad plan of this is, first to classify periodicities of various sorts, then to set forth the experimental factors that operate in each class, and to give in the end an indication of the views which the authors—themselves notable experimenters in the field—have formed as to underlying causes. The full and important bibliographic index contains about 300 references, of which about one-third centre in the Liesegang phenomenon. About twenty fall outside the last thirty years.

The kinds of periodicity discussed are shown by the authors' definition of the word: "the recurrence of some property or accentuation of a property at regular intervals of time, distance, or other quantity." The sub-atomic recurrences that give rise to periodicities such as Mendeléeff's are intentionally excluded. Three main classes may be distinguished. In one, the speed of a chemical reaction shows pulsations, time being here the variable; in another are the reactions or properties in which space is the variable, so that fixed space-patterns are formed, like the layers in an agate; and in another class the variable to which the pulses in properties are referred is not obviously time or space, but some adjustable condition such as degree of dilution or extent of mechanical stress.

One example of the third class is Holker's effect, in which a row of tubes of a colloid solution show alternating groups of 'thick and clear' when each tube is given a stronger dose of electrolyte than its left-hand neighbour had. Another example placed in this category (labelled "static periodicity") is found in the waxings and wanings of the mechanical and other qualities of some metals when subjected to continued cold-working.

The second class includes all the phenomena first studied thirty years ago by Liesegang: the stratification caused by the advance of a reagent into a jelly containing a second reagent. The valuable critical survey of the work in this class shows that although stratification is favoured by the presence of jellies, these are not essential to it. It can, for example, occur by the slow merging of gaseous ammonia and hydrogen chloride; yet even here it is to be noted that the smoke produced is a colloid, and so are the glass reaction-tubes. It is obvious, in all cases, that a prime necessity is that diffusion must be going on, and to that extent time-rates must come into the affair; but the authors say that there is nothing to suggest that the reaction-time curve itself is periodic. They are inclined to correlate the formation of Liesegang striæ with Holker's effect, already mentioned. Though much diverse work has been done, there is evidently much still to do before a full understanding is reached of the Liesegang phenomenon and, with it, of many structures that concern mineralogists and biochemists. The authors' survey will be very helpful to workers in this field.

The account of the work on periodic reaction-speeds, together with that on pulsating electrode-potentials, covers very interesting ground. Here the authors, in their own investigations, met what they call "the bugbear of work on periodic phenomena"; namely, the operation of essential but unidentified factors. This has led many other workers into puzzles and controversy; but Drs. Hedges and Myers' happy gift of devising crucial experiments has often enabled them to exclude irrelevant factors and to study the phenomenon at its simplest. For example, aluminium dissolving in alkali gives off hydrogen in pulses; is this merely due to the formation and subsequent discharge of supersaturated solutions of the gas, either in the metal or in the liquid? They make the aluminium one electrode of a cell containing the alkali; when it is made the anode, it dissolves and the hydrogen comes off in pulses—but at the other electrode; and when the aluminium is made the cathode, so that it does not dissolve, hydrogen is evolved from it—but smoothly. Hence the question is negatived. Again, it was found that certain cases of dissolution owed their periodicity to something in the glass walls of the containing vessel; and when the glass eventually 'tired,' periodicity could be restored by minute traces of various colloids. Eventually, the very important conclusion next mentioned was reached.

The core of the book is this: the authors show fairly conclusively that intermittent pulsations in a reaction $A+B$ are due to the presence of some substance, C, which must be in a certain special physical condition. This substance may be foreign to the net reaction; for example, metallic mercury will cause the spasmodic decomposition of hydrogen peroxide; but alternatively it may be one of the reagents themselves, appropriately treated beforehand. To mention one case, the dissolution of copper in a suitable acid goes by pulses if certain freshly made colloids are present, or alternatively if the copper itself has first been submitted to mechanical stress. The soft crystalline metals like lead and tin are not able to be activated for periodicity by being strained; the authors connect this with the faculty for self-annealing. With metals which have been only mildly strained, the property is apt to fade. Liquid mercury needs no special treatment; it is active without it.

What clearly emerges is that the seat of pulsation in a heterogeneous action is at an interface. Further, there are good reasons for suspecting that, despite some seemingly contrary evidence, no pulsating reaction is other than heterogeneous.

Drs. Hedges and Myers accordingly seek to go further; and, tentatively but suggestively, they refer rhythmic reactions, and rhythmic structures also, to effects of varying surface tension. There is evidence that this property, which itself affects reaction-speeds in a solution, can be a periodic function of the strength of a solution; and a valuable step forward will have been made if pulses in surface tension can be correlated with reaction pulses on one hand and with the Holker effect (and through it with the Liesegang phenomenon) on the other.

It still remains to explain why periodicity of any sort should occur at these surfaces. The evident connexion with catalytic action is commented on by the authors; but they seem to think that rhythmic movements of energy may be intrinsic in 'metastable' surfaces. It is quite possible, they say, that all catalysis is periodic in character, though only rarely measurably so. Many readers will probably argue that the factors which must, in that event, be invoked to explain the suppression of rhythm in innumerable observed cases, might just as well be used instead to explain its presence in a few. That is, we would make rhythm a result of superposed velocities, rather than stop short at a 'principle of periodicity.' Thus the reaction velocity in a volume of dilute reagents subject to catalysis at fixed surfaces in it will show pulsations, provided that the catalytic activity of the surface gradually increases until it causes a local 'explosion,' *i.e.* a reaction speed that outstrips the rate at which reagents reach the catalysing surface. An example is seen in the lecture experiment, wherein a heated platinum wire is hung above warm ammonia solution through which oxygen passes; the rhythm of accelerating catalysis culminating in explosion, with local exhaustion of the reagents and the renewal of the cycle, can be watched recurring for a long time. The molecular film-patch mechanism of surface catalysis, worked out by Langmuir and others, seems capable of describing conditions for such cases.

At the same time it is attractive to look upon a pulse inductor as a kind of bank of energy, as the fly-wheel of an engine; for it does behave as if it stored up energy gained from the reaction, delivering it again so as to stimulate the adjacent reaction when this would otherwise have slowed down. In this light we may survey Drs. Hedges and Myers' conclusions as to the physical texture needful in a pulse inductor. Collating their facts as to cold-worked metals and colloids, they believe that a metastable, amorphous form is essential. They do not clearly differentiate metastability from amorphism; definitely crystalline, but metastable, allotropic forms of metals do not happen to be mentioned as pulse inductors; but the case of liquid mercury acting in this way shows that the potential energy, which characterises a metastable variety, need not have been implanted in the substance by previous treatment, but may be gained from the reagents into which it is put. The factor common to pulse inductors might be crudely described as the ability to produce atoms the valency-bonds of which stick out of the substance. Thus it can be said that a pulse inductor deals out to the adjacent molecules some of its internal energy, derived from external sources and set free by the return of its own atoms to a more stable orientation.

An illuminating example of this 'relaxation' is quoted on p. 65; cold-worked copper spontaneously 'breathes' oxygen in and out for a long time; whereas stable copper under the same conditions scarcely takes up oxygen at all. One may perhaps be allowed to picture this, however imperfectly, as a slow union of oxygen with areas of active or abnormal atoms of the copper; when the film of oxide molecules has spread to the edge of a patch of normal copper atoms, the transition sets in rapidly at the boundary, which thus quickly invades the oxide film and causes the expiration of oxygen, demanded by the smaller affinity between oxygen and normal copper. A moderately quick renewal, from within the copper, of areas of active atoms would then make the cycle set in again; such renewal requires that energy shall be supplied to the copper from outside, either by previous cold-working, or else by the storage of energy evolved from the stoppage and fixation of gaseous oxygen upon the active atoms. A fairly good analogue is that of a sink, filled by a slow tap and intermittently emptied by a quick-acting siphon; gravitational energy here takes the place of chemical energy. (It would be interesting to know whether the oxygen expired in pulses from copper is chemically active, as hydrogen escaping from palladium, and other molecules newly released from combination, appear to be.)

The storage of energy here ascribed to pulse inductors, as it were in a delay-action fuze, may be compared with the similar storage of radiated energy that is seen within silica or fluorite when these are heated after being exposed to high-frequency rays; or, a better parallel here, in the photographic plate between exposure and development. (In passing, the 'reversed image' of a photographic plate suggests a periodic action.) Thus the time of relaxation can be long in a solid aggregate of molecules while no reagent is attacking the aggregate. In homogeneous systems, on the other hand, it is known from fluorescence measurements that the time of relaxation of the isolated molecules is extremely short; they do not appreciably store up energy, and accordingly, as has been mentioned, measurably pulsating reactions in truly homogeneous systems are suspected by Drs. Hedges and Myers not to occur.

These reflections are offered merely as a footnote to a work which gives an admirable experimental survey and classification of facts, new and old, that were in much need of being marshalled and brought to our notice. The book is bound to meet with a well-deserved success; and not among chemists only; the authors remind their readers that periodic phenomena are of high importance biologically. Physiologists, no less than physical chemists, will find here much to think about, even though the book describes no biochemical or biophysical researches; for a good deal in the rhythmic behaviour of the fibres of living tissue is surely connected with the factors that Dr. Hedges and Dr. Myers have found significant in their studies of unorganised materials.

Irvine Masson.

The Physiology of Growth.

The Fundamentals of School Health. By Dr. James Kerr. Pp. xvi + 859. (London: George Allen and Unwin, Ltd., 1926.) 35*s.* net.

"Local Education Authorities would be wise not only to facilitate and encourage investigation into local medical problems by members of their medical staff, but actually to expect and indeed require it. The problems are not only manifold but strangely significant and pregnant.

"For here is an expanding physiology, unexplored; here are the very beginnings of disease; here its cause may be searched with some hope; here it may often be prevented; here the physique and education of a nation are in rudimentary form —and whatsoever here be found by searching or proved by experiment becomes forthwith of value to the child, to the community, and to the growth of human knowledge."

In these words Sir George Newman, in his eighteenth annual report as chief medical officer of the Board of Education, just issued, points out the immense field of research into the physiology of growth which is offered by the presence in the nation's schools of the whole of the population during the most interesting and important years of development. Although there is now completely established a school medical service throughout Great Britain, with one whole-time school medical officer to 8500 children, but little has been done even to explore this abundant field. Local Education Authorities, frankly, are not interested in the question of research. Their medical staffs are overburdened with difficult problems of administration, and mere doctoring more than absorbs the whole of their available time.

The appearance of Dr. Kerr's book on "The Fundamentals of School Health" is therefore especially to be welcomed. Dr. Kerr has been exceptionally situated. Appointed thirty years ago as medical adviser to the most progressive of the provincial education authorities, he was in 1902 appointed medical officer to the London School Board. He was the first medical man in England to appreciate the importance of the subject he deals with, and was the first doctor to make a practice of daily visiting the schools. In 1911 the London County Council, recognising his unique qualifications, created for him the post of Research Medical Officer and, to give him full scope and opportunity, relieved him of all administrative cares.

The result of the research of a lifetime is to be found in this very remarkable book, with which there is none other in the English tongue that can be compared. It stands alone, and must for many a day stand, as an incomparable authoritative work.

Roughly, the forty-three chapters can be grouped into six logical divisions. First come five chapters which deal with heredity and growth, then twelve chapters dealing with general physical defects of the child, followed by five chapters dealing with mental development and intelligence; then eleven chapters directed to the physiology of the special senses, next five chapters dealing chiefly with problems of administration; and, finally, five chapters on the school environmental conditions of the child, including ventilation, heating, and illumination. It is impossible to do justice in a review to the care and labour which have gone to the making of this book. It is safe to say that it includes everything that has hitherto been learnt in regard to the subject, and much is founded upon original work carried out by Dr. Kerr or under his direction.

Of especial value are the chapters on the physiology of vision, upon ventilation, and upon illumination, but perhaps the most interesting are the early chapters dealing with problems of growth. Every one will agree with Dr. Kerr's denunciation of the general practice of treating averages as standards. One feels, however, that the author rather stresses environmental at the expense of genetic influences. Most of us would place the standard of height, for example, "somewhere between the Polish Count and Giant O'Brien," and for girth, "somewhere between the *Anatomie Vivante* and Daniel Lambert." Not so, Dr. Kerr; he is for Giant O'Brien every time. For Anglo-Saxon standards he draws arbitrarily a curve which is higher than the average attained by any but very exceptional groups. "They would represent the ideal young Anglo-Saxon as 6 feet high and weighing 11½ to 12 stones." Any one of our race failing to reach this standard would be considered by the author as having been stunted by environmental conditions. He adduces in support the measurements of the rowing members of Oxford and Cambridge University boat crews But surely a race is viewed as a congeries of genes, each of which, in respect to a character such as height, has its own maximum standard of attainment, and there must be innumerable Anglo-Saxon strains in which a height falling short of 6 feet by several inches is normal and not dependent upon environment. Do not they also serve who only sit and 'cox'?

Such criticism as this is not, however, to detract from the value of the book, but to point out the absorbing interest of the subject matter and its originality of presentment. The strong idealism of the author is shown in the tendency to stress environmental conditions. This idealism also causes him to leave the dusty road at frequent intervals in order to tilt at windmills—political, economic and administrative. He returns, however, to the straight path after every such adventure with renewed zest and ardour. While these excursions do not advance the author's theme, they serve to make the work extraordinarily interesting to read and to enliven a subject which might easily, by conventional presentation, have resulted in a dry as-dust disquisition.

It remains to say that, as befits the subject matte of the book, the type and format are unexceptionable, the illustrations and diagrams are numerous, and the tables clear and illuminative. While the work becomes immediately invaluable to all engaged in the problems of the care of the nation's childhood, it must remain to all time a classic.

Problems of Potato-Breeding.

Potato Varieties. By Dr. Redcliffe N. Salaman. Pp. xxii + 378 + 10 plates. (Cambridge: At the University Press, 1926.) 25*s*. net.

As the author says, the title of this book is noncommittal, but almost unreasonably so, for in addition to most exhaustive descriptions of all the commercial varieties, this treatise contains a very complete discussion of the various scientific problems connected with the origin, breeding, and cultivation of what the daily journalist delights in describing as the "comestible tuber."

Originally occupied in physiological research, Dr. Salaman has devoted the last twenty years to 'cultivating his garden' (and to some purpose), but the loss to medicine has proved a gain to agriculture. The diseases of the potato alone provide a fascinating subject for research, all the more seeing that the potato keeps up-to-date by falling a victim to virus diseases furnished with all the modern terrors of 'carriers' and environmental 'factors.' Of these diseases Dr. Salaman says: "By directly threatening one of the most important elements of the food of the people they become a question of national concern and their investigation a matter which no country can afford to neglect"—least of all, we may add, Scotland, for the trade in Scotch seed potatoes is one of the most important that the country enjoys. We are bound to notice the author's footnote. "The Ministry of Agriculture has devoted in all but a few hundred pounds to the elucidation of a disease the ravages of which are costing the country *at least five millions annually.*"

These insidious diseases, we learn, are known popularly by such names as 'curl,' 'crinkle,' 'mosaic'—epithets descriptive of characteristic appearances on the foliage. Their effect is to cause a progressive deterioration in yield, amounting, in the second year of infection, to 50 per cent. and more. Scotland, it appears, particularly north of the Grampians, enjoys a considerable immunity. The reason assigned is of much scientific interest. The guilty virus is ordinarily carried from one plant to another by insects—aphides are probably the worst offenders, and in the cool climate of the north of Great Britain 'green fly' is rarely found. Seed potatoes brought from Scotland may, consequently, be free from the disease. We have said 'may,' for Dr. Salaman has proved that the infection may be 'carried,' just as that of diphtheria and other human diseases may be. It is still unsettled in what degree the superiority of the Scotch seed potato is due to this tolerance, or to absolute freedom from the disease. Dr. Salaman does not go so far as some and state that the degeneration which attacks the tuber in the south is solely due to virus diseases: in his view it is still possible that there may be an environmental or physiological cause (such as immaturity) for the superiority of northern seed. There are many other unsolved problems, most of which our author notices; a bibliography of 177 items is evidence that he has cast his net widely.

When Dr. Salaman originally attacked the potato scientifically (under the inspiration, we believe, of the late Dr. Bateson) it was in the hope that the newly born science of genetics would give him useful results. It is somewhat sad to find the following passage under the heading of "The Application of Genetics to Variety Raising": "were we, however, to possess all the data we could desire we might still be wanting in the possession of that one essential gift, the eye of the fancier, the *flair* of the breeder. . . . Some of the best varieties have resulted from seed secured by impregnating some favourite but nameless variety with pollen recovered from several plants mixed together on the thumb nail before being applied to the expectant stigma." That is not the only discouraging feature to the geneticist. The potato, in common with so many varieties of cultivated fruits and vegetables in Britain, is genetically 'heterozygous,' and when 'pure lined' is likely to suffer a great loss of vigour. So much is this proving to be the case that it is doubtful whether—except in relation to plants which are normally homogamic, such as the cereals—the pure line will prove of much economic value.

Dr. Salaman is a thorough-paced Mendelian. To the presence of multiple genes he would attribute all the varying economic characteristics of the plant—yield, shape, cooking quality, and so forth. Of all the farm crops, none is more sensitive to environmental conditions such as soil, climate, and cultural treatment. Added to these there is the admitted variability due to the degree of infection by virus disease. On the figures adduced by the author, subject as they must be to these errors, it is permissible to question the existence of genuine segregation: the facts, such as they are, might be equally well explained on the unfashionable hypotheses of blended characters, or inheritance of acquired characters.

The book is produced in the style which distinguishes all the publications of the Cambridge Press, and it certainly constitutes the best textbook extant on the scientific problems of potato-breeding. As such, it should prove a welcome addition to the library of the scientific worker and, especially in regard to varieties, to that of the enlightened agriculturist.

Science, Invention, and Industry.

Old Trades and New Knowledge: Six Lectures delivered before a 'Juvenile Auditory' at the Royal Institution, Christmas 1925. By Sir William Bragg. Pp. xii + 266 + 42 plates. (London: G. Bell and Sons, Ltd., 1926.) 8*s.* net.

THE publication of Sir William Bragg's lectures to a 'juvenile auditory' at Christmas 1925 will enable a much larger audience than could be accommodated in the historic Albemarle Street theatre to enjoy what he has to say on the application of modern scientific discovery to the study of practical problems. Our earliest inventors are known only by their works, but just as it is one of the aims of the archæologist to inform us of the social habits of past races, so the scientific investigator finds it worth while to attempt to explain the technique used in age-long industries. By so doing he not only shows us the why and wherefore of processes evolved by centuries of patient groping and accidental discoveries, but also at the same time lays bare the fundamental principles on which future improvements depend. Through the ages men have gradually learnt to smelt, cast, forge, harden, temper, spin, weave, dye, fashion, fire, and glaze, producing utensils, implements, tools, weapons, garments, and ornaments, but never before has it been possible to unfold the laws on which such operations depend for their success.

The lectures cover wide and interesting fields of human endeavour, ranging from the study of the work of those who go down to the sea in ships to that done in peaceful cottages where wool and flax were spun into yarn by hand, and again to the hazardous business of mining, in which water, gas, and dust worked such havoc. In nothing has science wrought a greater revolution than in sea transport. To a seaman of the days of Elizabeth, the speed, regularity, and certainty with which passengers and goods are carried overseas to-day might well appear magical. Even in 1741, as we are told, Anson, after rounding Cape Horn, was ten degrees out in his reckoning. But with the coming of the sextant, the chronometer, and the Nautical Almanac, the mariner could fix his position with ease. Never was a nation's money more profitably spent than when Flamsteed was made Astronomer Royal at £100 a year, or Harrison given the £20,000 for his years of labour on the chronometer. To the compass and the sextant have now been added the gyro-compass, wireless time signals, wireless direction finding, leader cables, echo sounding, and even microphones placed on the bottom of the sea far from land. With such appliances collisions are avoided, channels navigated, and harbours entered even in fog.

While improvements in navigation have been mainly due to science, the progress in textile manufacturing owes most to the work of mechanical inventors. Kay's flying shuttle, Hargreaves' spinning jenny, Arkwright's water frame, Crompton's mule, and Cartwright's power loom were all designed to replace hand labour by mechanical appliances, and no one could wish for a clearer description of the processes involved than that given in the lecture on the weaver. To these inventors might have been added Eli Whitney, whose cotton gin made many fortunes, but riveted the fetters of slavery and led to civil war. In the textile industry, however, are many problems for research, and to these Sir William Bragg referred. In mining, too, it was the practical inventions of Savery, Newcomen, and Watt which made deeper mines possible, but it has been the study of scientific principles which has rendered coal-mining a hundred times safer.

It is in the lectures on metals, clays, and dyes that the reader will see how the whole armoury of modern science is brought to bear on apparently simple yet really difficult problems. Chemical analysis, X-ray examination, the microscope, the theory of electrons, atoms, and molecules and internal structure are all used in the attack, and each lecture provides evidence of the value of research to industry. To the ordinary observer nothing could look less crystalline than the clay on the potter's wheel, yet even in the finest clays composed of the finest particles there is a crystalline structure, but "unfortunately, the information, while quite conclusive on this point, is not easy to interpret because our knowledge of the new X-ray methods is only in its first stages, and some problems are too hard for us as yet." As it is with the work of the potter so it is with that of the dyer and the smith, and familiar operations carried out daily in villages all over the world are subjects for the highest studies. It is to be regretted that no such lectures as these are delivered to our working men, for after reading them it is easy to agree with the remark of J. A. Froude, who, addressing the students of St. Andrews, said "that every honest occupation to which a man sets his hand would raise him into a philosopher if he mastered all the knowledge that belonged to his craft." E. C. S.

A New Approach to Religion.

Reality: a New Correlation of Science and Religion. By the Rev. Canon Burnett Hillman Streeter. Pp. xiii + 350. (London: Macmillan and Co., Ltd., 1926.) 8s. 6d. net.

THE old apologetic for religion used to treat it, and its evidences, as if it were a branch of natural or historical science. Its truth depended on the accuracy of its cosmogony, the historicity of its mythology, and so on. All this is now recognised to be beside the point. Science and religion are regarded as two complementary methods by which different aspects of reality can be apprehended. Any satisfactory correlation of science and religion must supply a theory of the mutual relations of these two methods of approaching reality. So far as men of science are concerned, they may be said of recent years to have examined their own methods and subject matter pretty thoroughly. On the side of religion, too, a good deal has been done by philosophers such as Prof. Höffding, Prof. Alexander, and others. But we still await the promulgation of a satisfactory philosophy of religion by a theologian. The book before us makes a genuine and sincere attempt to supply this want.

Canon Streeter approaches the problem by first drawing a contrast between science and art. Between these two there are differences not only of method but also of subject matter. To take the latter point first; whereas science is concerned with the quantitative, or metrical, aspects of existence, art is concerned with its qualitative, or non-metrical, aspects. As regards method, there are two important differences: (1) Science states definitely, while art suggests; and (2) science explains observed data by bringing individual cases under a general law, whereas art reveals an inner spirit by embodying it in a concrete instance.

These contrasts between the methods and material of science and art serve to illuminate the contrasts between science and religion. Religion, like art and unlike science, is concerned with the non-metrical or qualitative aspects of the world, though it is with ethical rather than with æsthetic values that it deals. With regard to method, religion, like art, suggests rather than states; and, again like art, religion isolates some individual event or circumstance, and makes it symbolic of the whole of reality, or of some dominant aspect of reality.

Canon Streeter holds strongly that not only science, but also art and religion, reveal to us genuine aspects of reality, though they are different aspects. The contrast between science and religion may be expressed by saying that "what science gives us is a *Representation* of Ultimate Reality, and that this Representation is one that may be likened not so much to a picture as to a diagram." Whereas "what religion gives is also a Representation of Ultimate Reality, but one that is of the nature *not of a diagram but of a picture*." So that science and religion each give a representation which without the other is incomplete. One is like the ground-plan of Venice in Baedeker's guide, the other like Turner's famous picture, "Sunrise in Venice." These are complementary, though more or less incommensurable.

Science, then, supplies us with abstract diagrams, whereas religion, using the methods of art (myth, drama, parable, hymn, etc.), presents us with the qualitative aspects of reality by making us *feel* these "beyond the limits of our own experience." Hence, to test the 'truth' of any particular religion, its myths, etc., must be cross-examined. These, rather than the intellectual constructions of its theologians, indicate the spirit of a religion. No doubt, the question of the 'objectivity' of the 'values' of a religion is, in the end, a philosophical question. Religion cannot dispense with philosophy, or even with science, which contributes data for philosophical constructions, but philosophy is always secondary.

Canon Streeter himself is far from avoiding the philosophical issue. He applies the tests indicated above to Christianity. He inquires the meaning of the Christian 'myth' (which, however, he regards as history), and then proceeds to ask whether the values enshrined or symbolised in the myth are actually inherent in reality. He discovers that they are. He reaches this conclusion, not by the *a priori* reasonings by which theologians are accustomed to reach favourable results, but through a survey of scientific facts, largely from the biological sciences. Consequently, students of science will be able to follow this portion of the argument with patience, a thing they may often find difficult in this class of book. But in classing this volume with apologetic literature in general, we should not be acting fairly to Canon Streeter. It is a work of a very different type; one which all earnest students of the natural sciences would do well to read. J. C. H.

Our Bookshelf.

(1) *Man and Weather*. By Prof. Alexander McAdie. Pp. vi+99+18 plates. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1926.) 8*s*. 6*d*. net.

(2) *Air Ministry: Meteorological Office, London. A Short Course in Elementary Meteorology*. By W. H. Pick. (Published by the Authority of the Meteorological Committee.) (M.O. 247.) Second edition, revised. Pp. 127+8 plates. (London: H.M. Stationery Office, 1926.) 1*s*. 6*d*. net.

(1) Prof. McAdie's little book is written in an entertaining style calculated to impress meteorological principles on the memory. It consists of six popular lectures originally delivered in the Lowell Institute, U.S.A., in December 1924: (1) The strategy of weather in war; (2) weather in peace; (3) the structure of the atmosphere; (4) clouds, fogs and water vapour; (5) lightning; and (6) droughts, floods, and forecasts. The book should be most successful in awakening an interest in the subject, but it is marred by a quite unintelligible table on p. 62 representing the balance of precipitation and evaporation by land and sea. The unfortunate reader led into this quagmire is offered no helping hand from the author, who ironically observes: "From the data given above it would seem that the total rainfall for the globe is much less than the evaporation." This is no paradox; it is surely a physical impossibility that precipitation, being the complementary process of evaporation, should in the long run be less over the whole globe.

(2) Mr. Pick's book, which contains an appreciative preface by Dr. Simpson, is couched in the more staid language of a British Government publication. It skilfully compresses the fundamental principles of meteorology into a small compass, but in a future edition the author would do well to revise various statements in the light of most recent knowledge. Why, on p. 26, should relative humidity be deemed a more important meteorological matter than absolute humidity? Both are fundamental matters in the physics of the atmosphere, and as regards physiological effects it is now realised that absolute humidity is the more important condition. If there is a defective chapter in a generally good book, it is that on "Weather Lore," inasmuch as too strict a regard is paid to the letter of weather rhymes and too little to the spirit thereof. The countryman's 'February fill-dyke' is a very real phenomenon in seasonal hydrology, and one is not justified in assuming, as Mr. Pick does, that this necessarily implies a belief in much rain in a month which rainfall statistics show on the average to have relatively little rain. There is no reference whatever to the fact that towards the end of winter, after the season of small evaporation and little absorption of water by vegetation, the water-table is highest, and the rivers and brooks are normally fullest, being ready to cause flooding with less rain than would suffice at the beginning of winter in November. Again, it may be doubtful whether any one really takes the forty-day prediction associated with St. Swithin's literally; yet the spirit of the saying has just this much climatic foundation: that if disturbed weather once sets in about the middle of July, or for that matter at any time in July, it is liable in England to be very persistent, with a long succession of battering rainstorms running into weeks. We all know that type of July and August, and the countryman has embodied such climatic experience in a proverb the literal terms of which are (as Mr. Pick observes) quite untrustworthy. The actual date has probably no significance whatever, being just a landmark, and before the rectification of the calendar it corresponded to July 26.

L. C. W. B.

Penrose's Annual: the Process Year Book and Review of the Graphic Arts. Edited by Wm. Gamble. Vol. 29, 1927. Pp. xvi+127+70+72 plates. (London: Percy Lund, Humphries and Co., Ltd., 1927.) 8*s*. net.

This volume fully maintains the reputation the previous members of the series have earned for the editor and publishers. The newest item in it is a description by Mr. Fishenden of the Pantone process, which Mr. Ronald Trist has now so far perfected that he no longer objects to publication of its details. "Planished plates of suitable metal are first coated with an electro deposit of copper to a thickness of, say, five one-thousandths of an inch, and then with a chromium deposit of two ten-thousandths of an inch." The plate is coated with a solution of fish-glue and bichromate, exposed, washed, and burned-in as usual in photo-engraving. It is then treated with hydrochloric acid, which dissolves the chromium where it is exposed, but as it does not attack the underlying copper it cannot etch too deeply. The plate is next dipped into a solution of a silver salt, and then a few drops of mercury are rubbed over it. Amalgamation takes place immediately except in those parts where the chromium surface remains, and the mercury surface repels the ink without the use of water. The plate is now ready for trimming and mounting. The advantages of the process are many. It saves much time, as underlaying, re-proving, and fine etching are unnecessary. Fresh plates can be prepared as rapidly and cheaply as electros. Chromium "is five times harder than steel," and a plate that has been printed from every day for months shows by microscopical examination that each chromium-topped dot retains its original perfection. An impression from a Pantone block made with a 175 to the inch screen printed simultaneously with type on a rough surfaced paper shows how perfect the dot formation is.

The editor gives his usual summary of the year's progress, in which he points out the great advances being made in rotogravure colour printing now that the process is thoroughly practical, and at the end of the volume adds his "Note Book," dealing chiefly and critically with apparatus. "The Work of the Private Presses, VI., Essex House Press, 1898–1909," is treated of by Mr. Chas. T. Jacobi, with examples. A new system of music printing, "The Isotonic Notation," which is claimed to be simpler to learn as well as simpler to print than the usual notation, is described by Dom John Stéphan. There are other articles of technical interest and importance, besides the usual batch of illustrations to demonstrate the present degree of perfection to which the modern reproductive processes have attained.

English Life in the Middle Ages. By L. F. Salzman. Pp. 287. (London: Oxford University Press, 1926.) 7*s.* 6*d.* net.

THIS is an attractive, sensible, and useful book. Mr. Salzman has already published a similar work on the industries of England in the Middle Ages, and in this second volume he takes up the wider subject and does it even better. It is full of interesting and significant facts, well selected and well presented, with such an abundance of excellent illustrations as we may expect from the Oxford University Press.

Mr. Salzman's book is an admirable and more popular companion to "The Legacy of the Middle Ages" which the Oxford Press also published a few months since. The keynote of the two volumes is similar and a welcome sign of the new spirit in history teaching. The new point is the constant realisation of the fact that history is important to us just in proportion as we understand that we are ourselves a part of it and that the past has made us what we are. Mr. Salzman has this truth in view throughout, and when he talks either of literature, education, warfare, or law and order, is at pains to show, both how the work of our forefathers seven hundred years ago laid the foundations of our present life, and in what respects it has altered in the interval.

The chapters on education and literature are particularly good in this respect. In the former, Mr. Salzman makes clear the reason for the puzzling difficulty in the early study of mathematics. Why was arithmetic, which we now regard as the foundation of all exact intellectual discipline, then relegated to the Quadrivium or second stage in education, and only attempted by the few? The answer is that the Arabic system of numeration had not yet made its way into the schools, itself a historic fact of high social and intellectual import. In treating of language and literature Mr. Salzman brings out, with equal prominence and usefulness, the value of the contact of Anglo-Saxon and Norman French in the three centuries after the Conquest. To this we owe the simplification of English grammar, the wearing away of genders and inflexions, which has made our speech the universal and adaptable thing which it now is.

The illustrations have been ransacked from the libraries of western Europe, and are a striking proof of the wealth to be gained from the study of medieval illustrated manuscripts. F. S. M.

Transactions of the Institution of Chemical Engineers. Vol. 3, 1925. Pp. 137. (London: Institution of Chemical Engineers, 1926.)

THOSE holding the opinion that chemical engineering is as distinct and important a study as are the other better-known branches of engineering might well point to the contents of this volume in justification of their views. There is a series of papers on industrial water supply and steam pollution, an authoritative discussion of filtration, a description of the machines used in magnetic separation, and a couple of lectures on petroleum distillation and steam jets. The latest developments in steam generation are also considered, for the volume includes a good account of the Brunler internal-combustion boiler, which employs a flame burning continuously under water, and an interesting description of the Benson generator, in which water is converted into steam without ebullition by heating it under the critical conditions of temperature and pressure. These brief references will suffice to indicate the wide range of technological interest covered during the year. Of the papers themselves, it need only be stated that their general merit testifies to the vitality of this youthful Institution.

The Chemical Age Year Book, Diary and Directory, 1927. Pp. 155 + Diary. (London: Benn Bros., Ltd., 1927.) 10*s.* 6*d.* net.

IN addition to a very convenient diary, this book contains information of special interest to the chemist. Short notices are given of such subjects as research organisations, chemical and allied societies, patenting of invention, use of industrial chemicals, trade name of dye-stuff intermediates, certain stock-exchange prices, etc. Various tables of constants and chemical data are included. A chemical directory and a number of trade advertisements form a large part of the volume. At the present time there are so many excellent collections of physical and chemical constants available that the advisability of including such information, especially in an abridged form as in this diary, may be doubted. On the whole, however, the material selected for inclusion takes up only a small portion of the book, and the data may have definite value in special circumstances. The binding and general appearance of the book are excellent. This may partly justify the price, which is rather high compared with that of diaries generally. J. REILLY.

Letters to the Editor.

Stresses involved in Tests of Hardness, and a Table of the Comparative Hardness of Certain Metallic Elements.

In Nature of Jan. 23, 1926 (vol. 117, p. 117), I gave a description of a method of determining 'Hardness,' in which a cone of the material to be tested was pressed against a hard surface (sapphire), and the area of the flat thus formed at the point of the cone by the application of a known force was measured, the hardness being defined as applied force ÷ area of flat, that is, as the greatest stress which the material can sustain.

In all forms of tests in which hardness is determined by the effects of a crushing force (whether by the indentation caused by a hard ball or the flattening of a point or ridge) the stresses involved can be expressed as a volume-compressive combined with two shearing stresses,* and the principal points of interest can be illustrated by a simple example. Consider a cube the edges of which are the axes x, y, z (Fig. 1), and let a compressive force F parallel to z act on the x, y faces, while the other x, z and y, z faces are free from any external force. These are the conditions for crushing and they can be satisfied by supposing that a volume compression $F/3$ acts on all the faces, while the shears the components of which, each equal to $F/3$ parallel to z and x and z and y, act to increase the pressure on the x, y faces and to neutralise that on the faces x, z and y, z.

If k and n are the coefficients of volume compressibility and rigidity respectively, the result of the application of F is that the distance between the x, y faces is diminished by $\frac{F}{3}\left(\frac{1}{3k}+\frac{2}{n}\right)$, while between the x, z and y, z faces the distance is increased by $\frac{F}{3}\left(\frac{1}{n}-\frac{1}{3k}\right)$, and the maximum value which can be given to F in this expression may be taken as defining the hardness of the material.

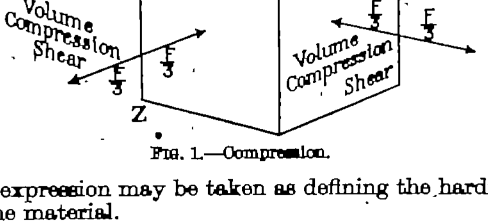

Fig. 1.—Compression.

In all solids there are two distinct limits to the strains which they can withstand, namely, increase of volume and shearing strain. There is no known limit to the volume compression which can be borne by a solid; in fact, k increases continuously with the pressure, and hence when fracture is produced by crushing, the cause is to be found in its inability to resist shear.

Whether the coexistence of volume compression with shearing stress alters the limits of strain for the latter is not known: it seems probable, however, that it does, or at any rate may, do so: but assuming for the moment that k and n are independent, the hardness of a solid is three times the force required to cause it to shear.

In addition to the stresses just mentioned, reference must be made to the friction between the surface of the test piece and the harder substance by which the crushing force is applied. This effect, which depends on the coefficient of friction, differs for each material, but in general adds to the apparent 'hardness' by opposing sliding motion which occurs at the area of contact.

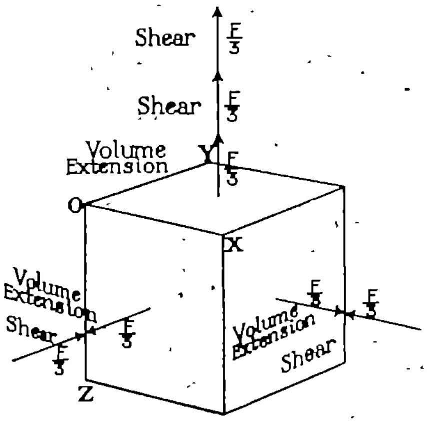

Fig. 2.—Extension.

In tensile tests the character of the stresses is inverted: volume compression is replaced by volume extension and the direction of the shear forces is reversed (Fig. 2).

In such tests rupture may occur either because the substance cannot bear the requisite volume extension or the requisite shear, and the nature of the break depends on which of the limits is the greater. When the limit of volume extension is small the material may be malleable although not ductile, but if it is ductile it is necessarily also malleable.

The accompanying table gives a list of 24 metallic elements arranged in order of their hardness. For

Table of 24 Metallic Elements arranged in Order of Hardness.

Hardness stated in tons/square inch.

	Metal.	Hardness.	Remarks.
1	Iridium	240	*M.*
2	Molybdenum	168	*M.* Wire.
3	Tungsten	144	Thin plate, slaty fracture.
4	Rhodium	128	*M.* Wire.
5	Nickel	112	*M.* Wire.
6	Chromium	109	Cast: Crystalline aggregate.
7	Cobalt	99	*M.* Cast.
8	Titanium	77	Plate, slaty fracture. Brittle.
9	Manganese	60	Cast: Crystalline aggregate.
10	Iron	56	*M.* From ingot made by Marriot process. Pure.
11	Copper	50	*M.* Wire.
12	Aluminium	29	*M.* Wire.
13	Vanadium	28	Crystalline aggregate. Brittle.
14	Palladium	28	*M.* Wire.
15	Silver	25	*M.* Cast.
16	Magnesium	22	*M.* Cast.
17	Zinc	21	*M.* Cast.
18	Gold	20	*M.* Cast.
19	Calcium	17·5	Crystalline aggregate. Brittle.
20	Cadmium	12	*M.* Cast.
21	Bismuth	8	Large, crystal.
22	Tin	7	*M.* Cast.
23	Lead	3	*M.* Cast.
24	Thallium	1·4	*M.* Cast.

most of these the hardness is of little practical importance, but the table does show how capricious this quality is and how apparently unrelated either to density, atomic weight, or position in the periodic classification.

Much depends on the condition of each specimen and on the treatment to which it has been subjected, as, for example, whether it is cast, forged, rolled, or drawn. In the cast state some of the metals consist of an aggregate of small crystals which separate comparatively easily, and in these cases the value found for their hardness relates to the junctions of the crystals and not to the crystals themselves.

Only those metals which are, to some extent at least, malleable, give a true measure of hardness in this form of test. (These are marked *M* in the table.) The others show the apparent hardness of the particular specimen used, depending, in part, on the closeness of the aggregation of small crystals, or on the relation of the crystallographic axes to the direction of the crushing force.

Many alloys have been tested. Various kinds of steel range from 700 tons/square inch for hardened carbon steel down to 56 tons/square inch for pure iron, and it is worth while to notice that none of the reputedly hard metals such as iridium approach the former figure.

A. Mallock.

9 Baring Crescent, Exeter.

Is Darwinism Dead?

The review in Nature of Jan. 15 of my criticism on Mr. Wells's somewhat antiquated biology has only just been shown to me, hence the delay in my sending this letter. I will make it as brief as possible, for I am only concerned with showing that the distinguished reviewer, Sir Arthur Keith, though he has doubtless been given a few sentences from my book for purposes of quotation, has not read the book itself.

(1) He says: "So adroitly does Mr. Belloc cover his verbal tracks with a smoke screen" that he cannot determine whether I am a 'fundamentalist' or a 'Darwinian.' As a fact, I cannot conceive myself being either, but the point is that no one who had read my book could have imagined that 'Fundamentalism' was the issue. The only issue was whether natural selection were the process whereby the differentiation of species came about.

(2) He says that I give 'with approbation' St. Thomas's conclusion that the creation of man was (in scholastic language) 'immediate': that is, special and direct. Had the reviewer read my book he could never have sincerely written that. I quoted this *exceptional* conclusion on immediate human creation to show that St. Thomas probably thought the creation of animate beings other than man to be 'mediate': that is, evolutionary.

(3) The reviewer is "forced to the conclusion" that I have never read "The Origin of Species." If he had read my book he could not possibly have been 'forced' to so foolish a conclusion. All I say in it on this matter is written in direct relevance to that work—with its only original (and erroneous) thesis of natural selection as the machinery of differentiation.

(4) He says that "Mr. Belloc resuscitates this ancient misrepresentation of 'accidental' and 'single' variations," and follows the sentence up with a good deal of irrelevant abuse. Had he read my book he would have found that I know all about Darwin's retreat in this matter, *and* am careful to point out that it was a muddled retreat. For the mathematical argument against natural selection applies just as much to a thousand cases out of a million as to one out of a thousand.

(5) He so completely misunderstands the example I take from the growth of horns that he clearly has not read the original passage but is judging from a chance sentence put before him, and even that he fails to grasp. My point—clearly stated, emphasised, reiterated—was that multiple adaptation is mathematically incompatible with the blind mechanical action of natural selection. Multiple adaptation presupposes design. The citation of the hormone as a disproof of God is wildly off my point. One might as well say that the presence of glue in a piece of woodwork disproved the presence of a carpenter.

(6) I have kept to the last the most damning count in this indictment. The reviewer sets me down as owing my remarks entirely to Mivart, as having merely copied Mivart's work of more than half a century ago: implying my ignorance of all since. Had he read my book he would have seen that I quoted from authority after authority among the highest names in modern biology from the beginning of the discussion to works which appeared so recently as three years ago. I give their actual words, which prove with what increasing force the old-fashioned Darwinian theory of natural selection has been beaten down. I end by a list of no less than forty such names—I might easily have made it a hundred. No one who had read my book could possibly have missed this continued and repeated citation of authority from every side, which is the principal feature of this section.

I conclude, therefore, that the reviewer has not read my book; for I hope that not even the most violent religious animosity could lead him to deliberate misrepresentation.

H. Belloc.

Not only did I read Mr. Belloc's book with great care, but I also took the trouble of turning up the works of some of the authorities he cites. On p. 12 he mentions, with bated breath as it were, "the great work of Vialleton." This "great work" is a very good elementary treatise on embryology which Prof. L. Vialleton, of the University of Montpellier, wrote for his students, and it stands in much the same relationship to the works of Charles Darwin as do those of Mr. Belloc to Shakespeare's.

Mr. Belloc cites Vialleton as his authority for denying the possibility of birds having been evolved from reptiles. On searching Prof. Vialleton's "Éléments de morphologie des vertébrés"—published in 1911—I found on p. 611 that after citing what Huxley, Owen, Seely, Mivart, and Gadow had to say about the matter, Prof. Vialleton concludes thus: "L'origine des oiseaux reste donc dans le plus complet mystère," which is a very different thing from denying their origin from reptiles. I have collected many other errors of a like kind, enough to convince me that Mr. Belloc's references are untrustworthy. Many of the authorities he cites, such as my friend the late Prof. Dwight, of Harvard, belonged to the generation which never succeeded in assimilating the teachings of Darwin.

Arthur Keith.

Radioactivity and the Heat of the Earth.

In his presidential address to the Geological Society, abridged in Nature of Jan. 1, Dr. J. W. Evans refers (page 15) to the above topic in the following words: "although the whole of the energy given out by radioactive elements, when isolated, is converted into heat, it is probable that a considerable proportion of the energy liberated by such elements, when they occur as rock-constituents, is used up in effecting physical, chemical, or atomic changes in the surrounding minerals.

"That much of the radioactive energy set free in the disintegration of radium and thorium is absorbed in other ways than in raising the temperature of the rocks is clearly shown by the formation in certain circumstances of 'pleochroic haloes' round radioactive minerals. This occurs especially in the case of zircon embedded in biotite mica. Such a halo is a sphere with a radius of about 30 microns, and has a minute zircon at the centre. It is of a darker and a deeper brown and far more pleochroic than the rest of the mica. The difference is usually assumed to be the result of ionisation by the radiations from uranium and thorium contained in the zircon. The possibility of atomic changes under the influence of the α-rays must, however, not be ignored.

"The formation of the haloes must involve a considerable absorption of energy, the magnitude of which will be realised when it is remembered that the mass of the halo may be some 15,000 times that of the zircon at its centre, and more than 300,000 times that of the uranium and thorium to which the halo owes its existence. Nor is it probable that this absorption is confined to the pleochroic haloes.

"It is, therefore, doubtful whether there is any considerable excess of radioactive energy available for raising the temperature of the earth."

In the absence of any experimental evidence in their support, such views as those expressed by Dr. Evans cannot be allowed to go unchallenged. They are liable to mislead, and to put unnecessary difficulties in the way of those who are interested in the trend of this aspect of geophysics, but are not sufficiently versed in the facts of radioactivity to form an independent judgment.

The occurrence of pleochroic haloes around radioactive inclusions in certain minerals certainly does show that *some* of the energy of the radiations emitted by the inclusions produces effects other than thermal ones; but before we are justified in stating that *much* of the energy is so expended, we must make an appeal to the available evidence, and this decides conclusively against Dr. Evans's view.

There is no evidence in favour of the view that an *appreciable* proportion of the energy liberated by the radio-elements, when they occur as rock constituents, is used up in producing changes of the kind suggested by Dr. Evans. In all determinations of the heat developed by radium, alone and with its disintegration products, the substance has been enclosed in a glass tube of sufficient thickness to absorb the α-rays completely, as well as more than thirty per cent. of the β-rays, and it is well known that the glass container rapidly becomes coloured by the action of the rays, the effects being quite analogous to those observed in minerals. Were Dr. Evans's views correct, we should expect that the heat development as determined experimentally would be considerably less than the value calculated from a knowledge of the number and energy of the rays involved; but this is far from being the case. Thus, for radium alone, that is, without disintegration products, the calculated heat development per gram of the element is 25·47 cal. per hour, whereas the measured value is 25·1 cal. per hour (Rutherford and Robinson) or 25·2 cal. per hour (Hess), and these experimental values probably require to be raised by 0·2 or 0·3 cal. per hour owing to incomplete absorption of the γ-rays from radium in the apparatus used (see NATURE, 116, p. 897, 1925).

Almost equal agreement is obtained between experiment and theory when we consider the total heat developed by 1 gram of radium together with its short-lived products. The results of experiment yield 135 cal. per hour (Rutherford and Robinson), and 137 cal. per hour (St. Meyer and Hess), both results probably being somewhat low owing to insufficient allowance for the effect of the γ-rays. On the assumption that all the energy of the rays is converted into heat, and with the latest data, the total heat production of radium and its short-lived products in equilibrium works out to be 137·7 cal. per hour per gram of the parent element (see *Phil. Mag.*, vol. 2, p. 1227, 1926). From the close analogy between the effects in glass and in minerals, it seems safe to conclude from these results that the energy of the radioactive rays expended in the manner suggested by Dr. Evans does not amount to one per cent. of the total energy, and is probably not more than about one-tenth of this value.

Determinations of the heat production in uranium and in thorium minerals have also been carried out experimentally. Here the effects are so small that the results cannot be expected to agree very closely with the calculated values. Nevertheless, the agreement is surprisingly good and gives additional support to the conclusion reached above.

Another aspect of the problem is worthy of mention. A rough calculation indicates that the energy of the α-particles emitted by the inclusion during the life of a representative pleochroic halo may amount to several hundred micro-calories. Were an appreciable fraction of this energy to be stored in the halo and liberated say by the application of heat, it is to be expected that the halo would attain a temperature reckoned in thousands of degrees. But nothing so violent occurs in practice. Glasses and minerals coloured by radioactive rays are restored practically to their original condition when their temperature is raised to from 200° to 400° C., and in the process they exhibit the phenomenon of thermo-luminescence with the emission of light of characteristic colour; but the energy so liberated does not produce catastrophic results, and is manifestly small.

The problem of the thermal history of the earth is unquestionably one of great difficulty, and in its elucidation much still remains to be done. But we cannot lightly dispose of the fact that radioactive processes must have exerted a profound and indeed a controlling influence in maintaining that youthful vigour which has characterised our planet throughout geological time. The effects of uranium, thorium, and potassium cannot be ignored in geothermal considerations, and in the absence of any experimental evidence to the contrary, we can continue to assert with confidence that practically the whole of the energy associated with the radiations emitted by these elements is available for raising the temperature of the rocks in which they occur.

University of Sheffield.

Progressive Lightning.

IN NATURE of Nov. 20 last, Prof. C. V. Boys has an article on some attempts to photograph 'progressive lightning,' in which he refers to observations of 'multiple flashes'—that is, flashes succeeding each other along the same path.

There is no doubt of the reality of these *appearances* of multiple flashes, but I have very serious doubts of there being more than one flash in reality.

Córdoba is an excellent place for the observation of lightning, as the electrical displays are frequent during the summer months, and they are some of the strongest I have ever witnessed (in several parts of the world). The Observatory is well situated on the bluff overlooking the river, with a clear view over the pampas in almost all directions for many miles. Displays are often observed at distances of forty to fifty miles and many pass directly over us. Houses of the astronomers and other buildings have been struck several times during my residence here, and one of the steel and concrete domes was struck once. In the early history of the Observatory one of the astronomers was killed in his room in the assistants' house.

Altogether I have observed many hundreds of brilliant flashes, as many close ones perhaps as distant ones. I have many times observed these 'multiple' flashes, usually two or three succeeding each other. They are strikingly clear and sharp and sometimes appear to vibrate. They certainly give the impression of there being distinct flashes, but I cannot conclude that this is a fact, because they are invariably seen only when the flashes are distant, usually too distant for there to be any sound. Now we have every reason to expect that just as many of this type of flash should occur near by as at a great distance if there are really several flashes instead of one. But in all my experience I have never seen a case near by; they are always at a great distance. One of the strongly marked characteristics of the near flashes, in appearance as in sound, is their sharpness and shortness—the nearer the shorter. Flashes within a hundred yards are sensibly instantaneous to both eye and ear, and *always single*.

From these facts I conclude that the 'multiple' flashes are due in some way to erratic refraction in the atmosphere.

It would not be without value perhaps for two observers, some twenty or thirty miles apart and in telephonic connexion, to test this matter by observing whether the flashes which appear multiple are observed to be so at both stations in cases where the flash is very close to one station and distant from the other.

C. D. Perrine.

Observatorio Astronómico de la
Nación Argentina,
Córdoba, Dec. 19.

I have to thank Dr. Perrine for his observations on my article on "Progressive Lightning." They are interesting as indicating some difference in the appearance of lightning in the Argentine, where the strokes are exceptionally strong, and that of lightning in Great Britain. Here without any question the appearance of the multiple flash is found when the distance is as little as a kilometre, and I certainly believe much less. In Cordoba Dr. Perrine only observes this when the flashes are so distant that thunder is barely heard. Such a distance here is from sixteen to twenty kilometres. I suppose here, with a flash near enough, even if it were multiple, the eye would be so dazzled by the primitive flash as not to be able to see those that follow, but it is difficult to account in this way for the great distance implied by the faint audibility of the thunder. I have seen a large number of photographs taken with an ordinary camera held in the hand, and not intentionally moved as Dr. Hoffert's was, but nevertheless not really fixed, which show the multiple flash, and the size of the flashes on the plates indicates that they must have been fairly near. At any distance such as sixteen kilometres the flash would occupy but a small portion of the plate.

I could have wished that Dr. Perrine had supplemented his eye observations with photographic records which would be easily obtained in so favourable a locality. It would appear that it is a suitable place for my proposed rocket experiment, that is, if the descent of the empty case and stick is not a danger as it is with me. I might add to my previous observations that the rocket, preferably of about three centimetres calibre, should be without a head but with one calibre extra of solid composition over the hollow left by the spindle, and that the usual proportion of coarse charcoal be retained, so that the whole length of the trail should contain live sparks to improve its conductivity. Such a rocket would attain perhaps double the usual height and move with immense speed.

If any question should arise as to the conductivity of the trail, this could be assured by allowing the rocket to carry up a hundred metres or more of fine copper wire arranged like a life-line so as not to kink. Owing, however, to the inconvenience of laying this in thunder rain I would first rely on the trail.

The Polishing of Surfaces.

In Nature of Sept. 4, 1926, Mr. J. M. Macaulay suggested that, in the process of polishing, surface layers were actually melted—the energy supplied being ample to produce melting, and the difficulty with regard to temperature disappearing if the heat, due to friction, was produced at points of contact rather than over large areas (the temperature at a *mathematical* point-source of heat being infinite). In Nature of Jan. 29, Mr. N. K. Adam contends that "it does not seem necessary to suppose that actual liquefaction occurs," since "the polisher will tear away the surface particles of the glass" and "some of these particles will naturally be redeposited elsewhere at random, thus forming the amorphous layer." Now it is difficult to believe that particles of glass spread at random will have a polished surface, even although these particles be of molecular dimensions, since each particle will be covered by a surface layer of gas, or other substance, which will prevent cohesion at ordinary temperatures. It might be contended that in the polishing process the particles torn from the surface had no time to assume a surface layer, but that is surely a highly improbable assumption. It seems to me that Mr. Macaulay's letter gives the key to the rational explanation of surface polish.

James Muir.

The Royal Technical College,
Glasgow, C.1, Jan. 31.

Perhaps my letter of Jan. 29 requires some further explanation. I did not suppose that the particles were redeposited as a dust on the surface, expecting them to coalesce spontaneously to a polished layer; this would of course be impossible. If, however, we examine what would happen to the *molecules* on the liquefaction hypothesis and on mine, it appears that mine is simpler and more probable. On the liquefaction hypothesis, the forces of adhesion between the moving polisher and the surface (constituting friction) are supposed to produce heat first; this heat then liquefies the surface layer. That means that the friction sets up irregular thermal vibrations in the surface molecules; it is then necessary to suppose that the energy of these vibrations is dissipated less rapidly than it accumulates, owing to the small thermal conductivity of the material; finally, the vibrations become so intense that the molecules can no longer stay in their positions in the solid, and 'melting' occurs. It must further be supposed that the surface layers remain liquid sufficiently long to flow to a plane surface, with whatever assistance may be given by the motion of the polisher.

My hypothesis states that the polisher adheres to the surface, dragging away small particles. In the same manner, at other localities, the adhesion of the surface to the polisher drags back some of the particles adhering to the polisher. Thus the polisher acts as a temporary support on which many particles are removed from one point to another. Hardy's work on static friction shows that this tearing away occurs under quite light pressure, despite the possible presence of surface layers of gas. Clearly the random removal of particles, only some of which need be of molecular dimensions, from one point of the surface to another, must result in forming an amorphous layer, if continued long enough.

If there is energy enough to move the surface molecules as a result of intense thermal vibrations —which is all that melting amounts to—there must be ample energy for the mechanical transportation of my hypothesis. Thermal vibrations are a notoriously inefficient method of producing a specific mechanical result. The result required is the moving of molecules from an ordered space lattice to a disorderly, amorphous layer; and the motion of the polisher, picking up and redepositing particles elsewhere, seems admirably adapted to produce this.

I have some difficulty in accepting Mr. Macaulay's theory that the polisher only touches the surface at a point. This seems almost incredible, with a moving piece of flexible material such as wash-leather. Further, even supposing that the contact approximates to point contact in the first stages of polishing, through projections on the surface alone touching the polisher, one would expect that these points would be worn or melted away long before the completely polished, plane surface was attained, so that there would be contact over considerable areas in the later stages of polishing. I should expect heat to be lost from the area polished at nearly the normal rate of loss from a plane area the size of the apparent contact between polisher and surface.

Wheat in 3500 B.C.

A short time ago I received from Prof. Poulton and Sir John Russell small samples of wheat grains found by Prof. Langdon, of Oxford, in a vase on the site of an ancient Sumerian house at Jamdet Nasr, seventeen miles north of Kish in Mesopotamia.

The wheat, which Prof. Langdon dates 3500 B.C., is of much interest, not only on account of its antiquity, but also because its grains are of a type associated with the more highly developed races of this cereal.

The identification of the races of wheat by their grains only is always difficult, and sometimes impossible. In this case, however, I conclude, from the features noted below, that they belong to a variety of Rivet wheat (*Triticum turgidum*), a wheat, so far as I am aware, unknown to the ancient Egyptians, and the first authentic ancient sample of this race which I have seen.

The characters of these grains, namely, large average size, blunt apex, very prominent dorsal hump, and asymmetry or lop-sidedness of some of the grains due to pressure of the flowering glume on one side, are all characters of *T. turgidum*, and the grains are matched exactly by several modern varieties, which we grow annually at the Agricultural Botanic Garden at Reading (see Fig. 1).

According to a letter from Prof. Langdon in the *Times* of Feb. 3, the opinion has been expressed that the grains are those of Bread wheat (*Triticum vulgare*) or of Club wheat (*T. compactum*), but the grounds upon which these conclusions are based are not given.

The view that they belong to *T. vulgare* may, I think, be neglected, for their prominent dorsal hump and the asymmetrical form of some of the grains are opposed to this identification. I am also unable to agree with the suggestion that they are grains of *T. compactum*. All known varieties of this race of wheat have been grown here and studied during the last thirty years, and the majority possess grains similar in form to those of *T. vulgare*, but smaller; a few uncommon representatives have the dorsal hump of *T. turgidum*, but the large size of Prof. Langdon's grains is against their classification with these.

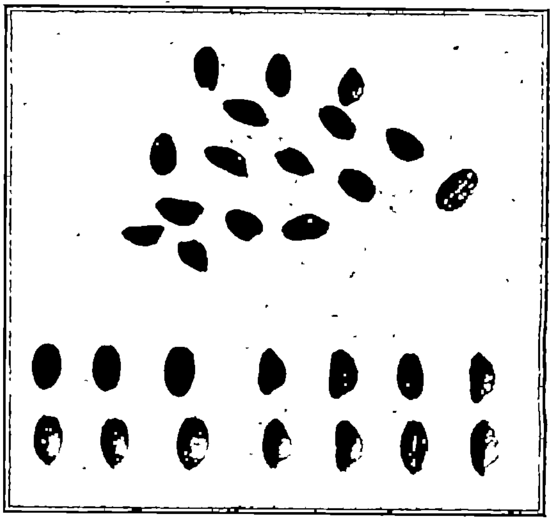

Fig. 1.—Upper group: grains of wheat found in a vase on the site of a Sumerian house (3500 B.C.). Two lower rows: grains of modern Rivet wheat (*Triticum turgidum*) for comparison. (Natural size.)

All trustworthy evidence we possess shows that Emmer (*T. dicoccum*) was the wheat first grown by the oldest civilised peoples, and I am of the opinion that these grains belong to the Emmer group of wheats; they leave us still without any clue to the origin of the Bread wheat series, but I hope that further discoveries in the region from which these have come will ultimately provide material for the solution of the problem.

Apart from its botanical interest, Prof. Langdon's discovery is of much importance, in that it has proved that the Sumerians were in possession of an advanced type of wheat at a very early date.

The Length of Light Quanta.

At the meeting of the American Physical Society in December last, Lawrence and Beams reported experiments showing that the length of light quanta is smaller than 3 cm. Experiments were made by me in the spring and summer of 1926 on the same subject with a similar result, though by a different method. While the experiments were begun, however, a theoretical consideration showed that a positive result would be very improbable, and so the results were not published. The reasoning was as follows:

It is well known that it is possible to obtain an oscillogram of a radio wave and that by a proper choice of apparatus (Dufour oscillograph) one can photograph the wave form for periods which are small fractions of a wave-length. No matter how small this fraction is, the photographic trace gives directly both the sine character of the wave and its frequency because it satisfies the differential equation $\frac{d^2y}{dt^2} + (2\pi\nu)^2 y = 0$. Therefore, every-day electrotechnical measurements show that quanta of long wave-length have an effective length (in the sense of Lawrence and Beams) which is very much shorter than the wave-length of the radiation.

In my experiments a glass prism spectrograph and a photographic plate were used instead of a photo-electric cell. A Kerr cell with nitrobenzol as material was operated by means of sustained oscillations of 30 metres wave-length. Spectra of various sources were photographed with the cell operated as described above, and these spectra were compared with those obtained by applying a small direct field to the cell. This field was adjusted by trial so as to give the same intensity as the high-frequency alternating field. In all cases the spectra were identical.

It was expected that if light quanta should have a length corresponding to the mean life of an atom, then since for an opening time of $T = \frac{1}{2} \times 10^{-7}$ some lines are longer and some shorter than T, a change in the relative intensity of lines would be observed. No such effect was observed. Further, if the nicols were crossed well, the direct field which had to be applied was the root mean square value of the alternating.

The spectrograph was a low-dispersion, large-aperture Zeiss instrument kindly loaned by Dr. Meggers of the Bureau of Standards. It was naturally impossible to observe the theoretical broadening by means of it.

Needless to say, the experiments of Lawrence and Beams and those of the writer are a continuation of the experiments of G. P. Thomson with canal rays.

A Polymorphic Oligochæte.

During a recent visit to North Wales an effort was made to increase our knowledge of its oligochæte fauna. The most interesting result was the discovery in three different localities of as many different forms of one worm, usually known as the Venetian worm (*Eisenia veneta* Rosa). In a rubbish heap near some gardens in Colwyn Bay I came across one specimen which closely resembles Rosa's type. Hitherto this has only been found at Kew, where it is probably an introduction. The Welsh specimen, however, has tubercula pubertatis on four segments on one side, while the normal two are on the other. This recalls the variety *zebra*. In a garden near by several specimens of a very different form occurred. In almost every British earthworm the girdle is much more fully developed dorsally than ventrally, but in these the conditions were exactly reversed. So characteristic is the appearance as to justify a distinguishing name, and this variety may be known as *tumida*. The third form was found under the bark of a tree along with several dendrobænic worms, and this closely resembles some of the other varieties which have been described.

We now have at least half a dozen well-marked varieties of this most unstable of all British worms, the list being as follows:

1. *Eisenia veneta* Rosa, *typica*. Kew Gardens, Sept. 1909. Colwyn Bay, Sept. 1926.
2. Var. *zebra* Mich. Ireland. Southern, 1909.
3. Var. *hibernica* Friend. Dublin, June 1892.
4. Var. *dendroidea* Friend. Malvern, 1909.
5. Var. *robusta* Friend. Kew, Oxford, Malvern and elsewhere, 1909.
6. Var. *tepidaria* Friend. Oxford, 1904.
7. Var. *tumida* Friend. N. Wales, 1926.

Some interesting problems present themselves in connexion with these facts, and a wide field for observation and investigation is opened up thereby.

Hilderic Friend.

Tuning-Forks with Parallel Prongs.

Attention has been directed by Mr. Maxwell (Nature, Jan. 22, p. 124) to an apparently extraneous overtone heard in tuning-forks, the pitch of which is one octave above the fundamental tone of the fork.

An explanation of the presence of this tone was supplied by the late Lord Rayleigh, who ascribed it to the action of unbalanced centrifugal force set up by the motion of the ends of the prongs in curved paths ("Collected Papers," vol. 1, p. 318).

A state of oscillatory tension thus comes into existence within each vibrating prong, and the frequency of this oscillation is double that of the transverse vibrations of the prongs themselves. The same holds for the bases of vibrating reeds and the ends of a vibrating wire.

Rayleigh obtained the octave tone by using a 256 fork on the box of a 512 fork. It may also be brought out by means of a Helmholtz or other resonator.

As Mr. Maxwell remarks, it is also heard when the butt end of the vibrating fork is placed on a table. With gentle pressure, the fundamental alone is heard, but with increased pressure, the octave above becomes audible, the pressure having to be increased as the amplitude of the prongs diminishes. By using a domestic spring-balance it may be found that the pressure required to bring out the octave of, say, a 512 fork with parallel prongs rises from 1 or 2 ounces to 6 or 7 ounces while the octave remains audible.

When the prongs are inclined to the stem, a component of the centrifugal force is not transmitted to the stem, and the vibration of the butt end due to this cause is of smaller amplitude.

G. E. Allan.

Department of Applied Physics,
University of Glasgow.

[Mr. W. Anderson, College of Technology, Manchester, writes to point out that the effect described by Mr. Maxwell is also referred to by Lord Rayleigh in his "Theory of Sound," vol. 2, p. 463.—Editor, Nature.]

Adsorption of Dyes to Silver Halides: a Correction.

In a letter on this subject (Nature, Dec. 25, p. 913), the number of dye molecules adsorbed at saturation to the surface ions of silver bromide crystal was given as about 1 dye molecule to 20 ions at pH 5·5. An error in the calculations has been found, which shows that the adsorption should be just ten times as great, namely, 1 dye molecule to about 2 ions of the lattice surface. Inasmuch as the dye adsorption increases with increased pH, it is probable that the limiting adsorption density occurs at the formation of a complete monomolecular layer. It may be possible to test whether the maximum sensitising effect is reached before this layer is completed.

The Electron as a Vector Wave.

By Prof. C. G. DARWIN, F.R.S.

THE spinning electron of Uhlenbeck and Goudsmit has brilliantly filled up a serious gap in atomic physics, but, while we cannot withhold our admiration from its successes, it is only fair to consider certain defects from which it suffers. When what is required is to double the number of states of the electron, it is at the least generous to introduce three extra degrees of freedom and then make an arbitrary (though not unnatural) assumption which cuts down the triple infinity to two. The electron is in fact given a complete outfit of Eulerian angles, even if it may not be necessary so to express the matter explicitly. Now we regard the electron as the most primitive thing in Nature, and it would therefore be much more satisfactory if the duality could be obtained without such great elaboration. The present communication is an attempt to do this; it is, I think, promising, though falling short of complete success, but as future stages would involve a very large amount of work, it seemed better to expose the theory to criticism at once, in case some serious objection can be made against the whole principle of it.

The above criticism of the spinning electron is perhaps partly aesthetic, but there are others. Thus though dynamical principles have been shown by both Thomas (NATURE, 117, 514) and Frenkel (*Zeit. f. Phys.*, 37, 243) to give doublet spectra correctly, yet neither of them has succeeded in casting the result in a rigorous Hamiltonian form, so that all the work on the spinning electron has a 'dressed-up' appearance, lacking in formalism. Again the wave mechanics (in this the matrix mechanics is better) definitely excludes half quantum numbers for the spin, and so would lead to triplets instead of doublets—1, 0, −1 instead of $\frac{1}{2}$, $-\frac{1}{2}$. It is perhaps also not unfair to argue that the quantum mechanics is largely guided by the principle that nothing unobservable is to be explained, so that a theory is to be regarded as suspect, which introduces a large number of higher quantum states of rotation, only to bar them later.

The advent of the wave mechanics must have suggested to many a way out of these difficulties by assimilating the electron to a transverse rather than a longitudinal wave, for this at once provides the number of states with the necessary factor 2. The idea involves difficulty when more than one electron is present; we shall discuss and tentatively meet this difficulty later, but a necessary preliminary is to obtain a system of equations for the single electron. In doing so we are endowing it with an intrinsic duality to which there is no direct analogue in dynamics, so that the only guidance we have is that the equations must be of the wave form (to conform to classical dynamics in the limit), and must be such as to give correctly the structure of doublet spectra. It is scarcely conceivable that the equations should not involve the Schrödinger functions, and this excludes, as a great many trials showed, any wave type built on lines like the electromagnetic equations, for the Schrödinger function will not tolerate a *divergence* relation of any kind. Moreover, such types of wave do not appear to exhibit those qualities of approximate degeneracy which are implied by the Paschen Back effect. It is, however, possible to construct by a much more inductive process a system of waves, of a vector character though not transverse, which completely reproduces the doublet spectra, and then to generalise from this.

The general character of doublet spectra is given by having two *dependent* variables, each of which nearly satisfies the same equation, say $Df=0$ where D, depending on x, y, z, t, is the operator in Schrödinger's equation. Let α, β, γ, δ be small perturbing operators in x, y, z, t, and solve the equations

$$\left.\begin{aligned} Df+\alpha f+\beta g&=0 \\ Dg+\gamma f+\delta g&=0 \end{aligned}\right\}, \qquad (1)$$

Near any characteristic W_n of $Df=0$ there are then two solutions of (1) with just the right type of degeneracy. Our task is, therefore, to discover forms of α . . . δ which will give the observed values of W for doublet spectra, and this is not so hard as might appear at first sight.

The *terms* of a doublet spectrum are very conveniently epitomised as follows. We take $k=0$, 1, 2 . . . for s, p, d . . . and $-k \leq m \leq k$, m being integral. For all values of m solve the following equations for $\overline{W}$:

$$\left.\begin{aligned} a_m[\overline{W}-\rho m-\omega(m+1)]-b_{m+1}\rho(k+m+1)&=0 \\ b_m[\overline{W}+\rho m-\omega(m-1)]-a_{m-1}\rho(k-m+1)&=0 \end{aligned}\right\}, \quad (2)$$

where ρ, ω are the Landé constant for doublet separation and the normal Zeeman effect in energy units. It will be found that the solutions give $\overline{W}$ as the distances of all the Zeeman levels from the centre of gravity of the terms at all strengths of magnetic field. (The equations give two end solutions of different form from the others, and these give the two extra members for one component of the doublet.) The above equations were found by solving the complete problem of the spinning electron and then adjusting the constants by trial; a_m and b_m are then the coefficients of a spherical harmonic for the two directions of spin. We shall not further inquire into their meanings; when suitably normalised they will of course be connected with intensity, but we need feel little doubt that intensities will come right on practically any theory.

By trial with $k=1$ and 2 it is easy to construct the operators α . . . δ and these are then found to work for all cases. The equations (1) are:

$$\left.\begin{aligned} \left(D-\frac{2\pi eH}{ch}\right)f+\frac{1}{2}\frac{Ne^2}{mc^2}\frac{1}{r^3}(-iR_1g-R_2g+iR_3f)&=0 \\ \left(D+\frac{2\pi eH}{ch}\right)g+\frac{1}{2}\frac{Ne^2}{mc^2}\frac{1}{r^3}(-iR_1f+R_2f-iR_3g)&=0 \end{aligned}\right\}, (3)$$

In these D is the Schrödinger operator, written in the form of Dirac (*Proc. R. S.*, **112**, 661) with the view of relativity generalisation :

$$D=\nabla^2-\frac{1}{c^2}\frac{\partial^2}{\partial t^2}-\left(\frac{2\pi mc}{h}\right)^2+2\cdot\frac{2\pi i}{c^2h}\frac{Ne^2}{r}\frac{\partial}{\partial t}$$
$$+\frac{2\pi ieH}{ch}\left(x\frac{\partial}{\partial y}-y\frac{\partial}{\partial x}\right)+\left(\frac{2\pi Ne^2}{ch}\right)^2\frac{1}{r^2}$$

and

$$R_1=y\frac{\partial}{\partial z}-z\frac{\partial}{\partial y},\ R_2=z\frac{\partial}{\partial x}-x\frac{\partial}{\partial z},\ R_3=x\frac{\partial}{\partial y}-y\frac{\partial}{\partial x}.$$

N is the atomic number of the nucleus, and we have reversed Heisenberg's process of deriving Landé's doublet formula from the mean of $1/r^3$. As it will be needed later, we here note that with the present formulation the time occurs in f and g in the form $exp - i\frac{2\pi}{h}(mc^2+W)t$. In spite of their appearance the equations (3) are symmetrical in x, y, z, when $H=0$.

The presence of coefficients Nex/r^3, etc., is a strong invitation for us to generalise, since they are simply the electric forces. Moreover, this generalisation is required if we are to show that the anomalous Zeeman effect is the same phenomenon as the doublet effect We first split the two equations into four. Multiply by arbitrary constants a, b and add. Then do the same with ia, $-ib$; $-b$, a ; ib, ia. We call the quantities $af+bg$, etc., X_1, X_2, X_3, X_4. (The process is nearly, but not quite, the same as taking real and imaginary parts of (3).) The equations then become :

$$\left.\begin{aligned}DX_1-U_1X_4-U_2X_3+U_3X_2=0\\DX_2-U_2X_4-U_3X_1+U_1X_3=0\\DX_3-U_3X_4-U_1X_2+U_2X_1=0\\DX_4+U_1X_1+U_2X_2+U_3X_3=0\end{aligned}\right\}, \qquad (4)$$

where

$$U_1=\frac{1}{2}\frac{e}{mc^2}\left(E_y\frac{\partial}{\partial z}-E_z\frac{\partial}{\partial y}\right),$$
$$U_3=\frac{1}{2}\frac{e}{mc^2}\left(E_x\frac{\partial}{\partial y}-E_y\frac{\partial}{\partial x}\right)+i\frac{2\pi e}{ch}H_z.$$

These equations, which are really only two, are now in vector form for space transformations, regarding X_4 as a scalar and X_1, X_2, X_3 as a vector. We can therefore take the magnetic force in any direction by adding on to U_1, U_2 terms like the last in U_3. It remains to apply the relativity transformation. The first point to observe is that (4) is not in space-*time* tensor form. To make it so we must use the fact that with sufficient approximation $-i\frac{2\pi}{h}mc^2=\frac{\partial}{\partial t}$. Remembering that E_x is the 14 component of the force tensor, this shows that the equations must be put in the form

$$\frac{\partial}{\partial t}DX_1-V_1X_4-V_2X_3+V_3X_2=0,\text{ etc.}$$

where

$$V_1=-i\frac{\pi e}{h}\left(E_y\frac{\partial}{\partial z}-E_z\frac{\partial}{\partial y}\right)+i\frac{2\pi e}{ch}H_x\frac{\partial}{\partial t},\text{ etc.,}$$

This is now *dimensionally* a possible tensor equation, but is not in fact covariant for space-time transformations. It is necessary to take the electric terms in V to be twice as large as they really are ; this is exactly the trouble of Uhlenbeck and Goudsmit. We shall discuss it later, for the present simply doubling the first factor in V_1, etc. Now write $x_1x_2x_3x_4$ for x, y, z, ict, and ϕ_1, ϕ_2, ϕ_3, $-i\phi_4$ for the vector and static potentials ; also for the six forces put $F_{12}=\frac{\partial\phi_2}{\partial x_1}-\frac{\partial\phi_1}{\partial x_2}$, etc. Remembering that $\partial/\partial x_4$ is much larger than $\partial/\partial x_1$, etc., and that H is much smaller than E, we add on certain insensible terms and obtain as our final equations

$$\left.\begin{aligned}T_4X_1-T_1X_4-T_2X_3+T_3X_2=0\\T_4X_2-T_2X_4-T_3X_1+T_1X_3=0\\T_4X_3-T_3X_4-T_1X_2+T_2X_1=0\\T_4X_4+T_1X_1+T_2X_2+T_3X_3=0\end{aligned}\right\}, \qquad (5)$$

where

$$T_1=\frac{\partial}{\partial x_1}\left\{\sum_a\left(\frac{\partial}{\partial x_a}+i\frac{2\pi e}{ch}\phi_a\right)^2-\left(\frac{2\pi mc}{h}\right)^2\right\}$$
$$+i\frac{2\pi e}{ch}\left(F_{23}\frac{\partial}{\partial x_4}+F_{31}\frac{\partial}{\partial x_2}+F_{41}\frac{\partial}{\partial x_3}\right).$$

On the present view, apart from the introduced factor 2, these equations constitute the ultimate dynamics of a single electron. It will not alter the observed values, and will perhaps fit better with future generalisations if throughout (5) the operators $\partial/\partial x_1$, etc., are replaced by $\frac{\partial}{\partial x_1}+i\frac{2\pi e}{ch}\phi_1$, etc., as they are in D.

The first three equations of (5) are antisymmetric tensors of the second rank and the last is scalar, but the variables can be permuted according to the following scheme, so that any one of the four equations is the scalar :

$$\begin{matrix}X_1\\X_2\\X_3\\X_4\end{matrix}\rightarrow\left\{\begin{matrix}X_4\\X_3\\-X_2\\-X_1\end{matrix}\right.\rightarrow\left(\begin{matrix}-X_3\\X_4\\X_1\\-X_2\end{matrix}\right.\rightarrow\left(\begin{matrix}X_2\\-X_1\\X_4\\-X_3\end{matrix}\right), \qquad (6)$$

The existence of these permutations means that to regard the X's as a vector is an unnecessary restriction, to which it may not always be convenient to submit. For example, by allowing a different rule of transformation the theory could be put in terms of four purely real quantities.

We must next consider how the solution will go when more than one electron is present. This is a most important matter, for the replacement of independent by dependent variables might entirely alter the counting of the number of solutions. We shall omit relativity considerations and so may use (4) instead of (5). At first sight the most natural extension would be to regard X_1, etc., as functions of two sets of x, y, z ; thus the first equation of (4) would become

$$(D+D')X_1-(U_1+U'_1)X_4$$
$$-(U_2+U'_2)X_3+(U_3+U'_3)X_2=0.$$

The effect would be to double the number of solutions, but it would seem that they would sort out as $2+2$, not $3+1$ as is required. We need a process which will give $4+4$ solutions, reduced to $3+1$ by Heisenberg's resonance principle (*Zeit. f. Phys.*, **38**, 411). This could probably not be done for most vector waves, but the permutations (6) suggest a way out; for in combining the two sets of variables there is no particular reason to select the same permutation of both. The actual number of possible selections is easiest seen from (3), where in adding the effects together we can interchange the meanings of f and g. We shall in this way get two systems of equations each with four solutions, just the number required. The question of two or more electrons is, I think, the most serious difficulty for the present theory, and this is only intended as an incomplete and tentative suggestion as to how it may be met.

Finally, we must consider the factor 2 which had to be introduced to obtain the tensor form. This is evidently the original difficulty of Uhlenbeck and Goudsmit. It was removed by Thomas, who showed that a rigid body when accelerating exhibits a sort of rotation on account of the kinematics of relativity. This brilliant explanation resolves the disagreement, but it really imports a foreign idea into mechanics; indeed relativity and rotation do not take at all kindly to one another, and it is not surprising that no formal Hamiltonian method has been found to cover what is really a blemish in geometry rather than dynamics. As we here have nothing corresponding very exactly to velocity, we cannot use the same type of argument. But regarding the matter from a more abstract point of view, may we not perhaps draw an inference from the fact that our work has forced us to have equations of the third degree? Relativity is essentially a point theory and is governed by a quadratic form. To a first approximation motion is controlled by this form, and the associated wave equations are of the second degree. Now we have seen that the actual wave equations, though approximately of the second degree, are more accurately of the third. Taking the analogy back, may we not conjecture that the quadratic form of space-time wants amplifying in some way (I fear the idea is quite vague) by terms of the third degree, and that the reason why Thomas and Frenkel did not obtain a formal Hamiltonian is because 'quadratic' dynamics is only an approximation, which cannot be perfectly represented by importing into relativity theory the foreign idea of a rigid rotating body. But this speculation is too indeterminate to pursue further at present.

Nerves and Muscles: How we Feel and Move.

By Prof. A. V. Hill, F.R.S.

It is not an easy task to give the Christmas Lectures at the Royal Institution, especially on a subject like physiology, in which experiments are much more difficult than in some others, at least when required to work without fail, to be intelligible and not to cause offence. The difficulty is increased by the fact that one's audience does not consist simply, in the words of the Royal Institution, "of juveniles between the ages of 10 and 16"; one finds oneself addressing distinguished adults in many walks of life, and not only these, but also through the publicity given to these lectures in the press, a considerable proportion of the people of Great Britain. One must reflect, however, in preparing them that they are intended for 'juveniles,' and that if others dare to come they do so at their own risk and will be assumed to be 'juveniles' for the purpose of the lectures. It is true, as a matter of fact, that most lecturers are apt to pitch their lectures at a level much too high for their audience, and that by attempting to make them interesting to a child of thirteen they may well succeed in absorbing the attention even of adults comparatively expert in the matter with which the lecture deals. We all like to have things put to us simply, and no lecturer to a juvenile auditory should pay any attention whatever to people above the age of sixteen.

The Christmas lectures at the Royal Institution are intended to include a considerable number of demonstrations and experiments, and without the use of live animals experiments on the functional working of the body are impossible. Two fortunate facts, however, make it practicable to give suitable physiological demonstrations at the Royal Institution: (1) that the isolated organs and tissues of dead cold-blooded animals will continue to function for considerable periods after removal from the animal; and (2) that in recent years a great variety of perfectly good physiological experiments, often of precise quantitative as well as qualitative significance, have become possible upon men; and if upon men, then also upon children.

The fact that isolated tissues of animals will function for a long time after removal, although a commonplace of phsyiology, is not generally realised, and in itself is a matter of entrancing interest to those who come upon it for the first time: it awakens all kinds of questions, scientific and philosophical, which not only a 'juvenile' but also an adult urgently desires to see answered. The beating of an isolated heart, which will continue for hours or days after removal from its previous owner, provided that it be properly treated, is an extraordinary eye-opener to most people previously ignorant of phsyiology. There are few physiologists who do not remember the astonishment and interest which was aroused in them by their first sight of this phenomenon, or of the reflex movements of a frog whose head has been cut off, or of the contraction of a muscle preserved, sometimes for days, in salt solution; or of the electric current produced by an isolated nerve, or of the many other strange things that happen to little bits of tissue removed from the ordinary environment which their previous owner supplied. It is such things that bring physiology first into the region where exact experiments can be made, and allow the factors at work in living tissues to be examined carefully and at leisure in the laboratory. The astonishment which we, as physiologists, have felt at intervals at such things, and which, if we have not grown too old, we still remember, is one thing we can and should communicate to our listeners, not only perhaps at the Royal Institution, but also at our classes in universities. The experience of the lecturer himself, at such a course of lectures as these, is valuable as showing him the kind of thing that appeals to intelligent, keen, unsophisticated, and natural people. There was no doubt from their applause that the audience approved of experiments in which the functions of organs were revealed by such experiments on isolated tissues.

Even more, however, than experiments on surviving portions of dead animals did the audience appreciate the fact, which I am sure many of them had never realised before, that experiments of all kinds on the mechanism of the body can be performed on man, or in this case on children, without discomfort or danger. How many are the things which, when we were young, we wanted to know about the machinery inside which we live—and nobody told us. Gradually, perhaps, we thought that these things were not to be known, or were unknowable; gradually, perhaps, we reached the state, in which I fear a good many adults exist, of regarding the machinery of the body as something unwholesome or 'nasty.' If my audience had been simply one of adults, I might perhaps have been afraid of shocking them in taking a life-like model of a man to bits and trying to fit it together again, after describing its various parts. In the case of children no such fear is necessary. As I have already said, there are very few small boys and not many grown men who do not want to take machinery to bits to see how it works; and children are quite ready to realise that they live inside a mass of complex and beautiful machinery, and are only too glad to be given the chance of taking it to bits, at any rate scientifically speaking, and examining its parts.

To a child there is nothing 'gruesome' about seeing the heart beating in a live man, or in watching the food (by means of X-rays) travel along his inside; nor are they inclined to faint, as some adults are, if one amplifies the sounds made by a human heart, or shows a kinematograph film of the blood corpuscles swarming through the capillaries of the lungs The advantage of the audience at the Royal Institution is that they are natural people without any obsessions, so one can speak to them as one natural human being talking to another. Possibly some adults may have thought that the children *ought* to have been shocked by some of the experiments we performed; I am sure, however, that very few of the children themselves lived up to such an expectation. It is only by continually suppressing one's desire to know more about, and to understand, the body in which one has to make a home for so long, that one gradually develops an obsession that there is something unnatural, unclean, or 'gruesome' about it.

It was most instructive to note which of the demonstrations, and which of the lantern slides, appealed most to the audience. Of the slides the one that seemed to please the audience best was a simple little diagram, taken from Cannon, showing how the food is propelled along the alimentary canal by a peristaltic wave, consisting of a contraction behind and a relaxation in front of the portion of food to be moved. This little diagram evoked prolonged clapping. I suppose many of the audience had long wondered how the food moved along their insides, especially perhaps at Christmas time, and maybe had wanted to ask but had found nobody to tell them. Another slide they obviously admired was a simple diagram of the central nervous system, taken from Prof. Pear's book, "Skill in Work and Play," by which I described how they themselves, sitting up aloft in the cortex of the brain, were able to carry out all kinds of automatic, or semi-automatic, activity by means of the 'telephone exchanges' existing in the cord below, and were able to appreciate muscular movement by the messages from muscles, tendons, and joints which pass up along the afferent nerves and into the different levels of the nervous system. Another slide which evoked obvious approval was a simple piece of arithmetic by which I explained how the greater the length of a race the slower one had to go. This is a fact of which we are all aware, but only recent progress in physiology has made clear what are the factors which determine it. The body has a certain 'income' of oxygen and a certain 'credit' upon which it can draw. If the 'credit' has to spread out over a longer period, less of it can be spent per minute, the effort must be smaller, and the speed lower. The fact that they obviously approved of this simple arithmetic, which certainly contained nothing sensational or dramatic, is a tribute to the intellectual level of the audience.

The first lecture dealt with "Nerves and the Messages they Carry." Isolated nerves and muscles were shown working, the electric current produced by an excited nerve was demonstrated, and an experiment was made on the stimulation of the ulnar nerve of a child. The messages coming along nerves were described, and the central nervous system was likened to an automatic telephone exchange.

The second lecture dealt with "Muscles and How they Move." In this, isolated muscles were stimulated, and a competition was organised between the muscle-nerve preparation of a frog and the muscles of a child stimulated through the ulnar nerve. The child won easily, because his circulation was able to supply his muscles with the oxygen they required in order to do the work, while physical diffusion alone was unable to bring oxygen rapidly enough to the frog's isolated muscle, which therefore rapidly fatigued. The electric change of the human heart was shown, and the physical and chemical basis of fatigue was discussed.

The third lecture dealt with "The Heart and Some other Muscles," chiefly with the heart. X-ray pictures of the alimentary canal after an opaque meal were followed later by a demonstration, kindly organised by Messrs. Watson and Sons (Electro-Medical) Ltd., in which a subject drank an opaque meal, which could be observed passing down into his stomach. Following this was an X-ray demonstration of the heart of the lecturer and others. The lecture had been started by a demonstration, organised by the Marconiphone Company, Ltd., in which the sounds made by the heart of a child were rendered audible throughout the hall. In the fourth lecture I dealt with "The Lungs and Blood: How the Muscles get Air and Fuel," in which perhaps the chief demonstration was that of a wonderful kinematograph film by Prof. Krogh, of Copenhagen, in which the blood corpuscles are seen circulating in the tissues of a frog. There is no means of which I am aware so good as this film of showing what the circulation of the blood really means. We discussed the energy derived from the fuel burnt in the muscles, and we saw experimentally how the oxygen consumed by man can be measured.

In the fifth lecture, "Nerves and Muscles Working Together," I discussed the basis of organised muscular movement, the nature of muscular skill and of muscular sensation, and all those automatic, or semi-automatic, actions of which a large part of our being is composed. A slow motion kinematograph film of a dancer, and another of a falling cat, were employed to emphasise the wonder of muscular skill, while a demonstration of the 'psycho-galvanic reflex' showed how our emotions cannot be hidden from certain quite simple physical apparatus. The sixth lecture, "Speed, Strength, and Endurance," dealt with an application of some of these matters to such things as mountain climbing and athletics; the importance of an adequate supply of oxygen was demonstrated by an experiment on a boy who pedalled a bicycle, breathing oxygen at only two-thirds of the ordinary atmospheric pressure, until very tired, and was almost immediately relieved—and pedalled with renewed vigour—when given oxygen in high concentration. Finally, it was emphasised how a capacity for severe muscular effort depends mainly on simple considerations of energy, and of skill in the economy of energy, and how certain predictions can be made of a man's athletic capacity by means of physiological measurements.

As I said in my first lecture, many people who own motor-cars know very little about the insides of them and how they work, which is distressing enough, especially when they go wrong. How many more who own perfectly good bodies have only the vaguest idea of their machinery, or of the meaning and importance of the various parts. In these lectures I tried to give my audience some idea of the working of two of the most important parts of the body. One cannot hope yet to understand our living machinery in full, but even the little we know already can add delight to physical exertion, and can make us realise the complexity of muscular skill and the nature of strength and endurance. The effort to understand will help us to appreciate the beauty and wonder of the devices with which our bodies are endowed; and when we begin to understand a little we shall soon want to understand much more.

Obituary.

Dr. Eugen Hultzsch.

By the death at Halle on Jan. 16, in his seventieth year, of Eugen Hultzsch, the study of Indian epigraphy loses one of its most ardent and painstaking followers. Born in Dresden, he was educated at Leipzig and Bonn, studying under Aufrecht, the famous Sanskritist. From 1882 until 1886 he was assistant professor of Sanskrit at Vienna. He was then appointed epigraphist to the Indian Government, remaining in the Service until 1903, when he retired and accepted the chair of Sanskrit at Halle. This he held until his retirement some time after the War. During the greater part of his service in India, Hultzsch edited *Epigraphia Indica*, to which he contributed many valuable articles. His own researches were very largely devoted to the inscriptions of the Presidency of Madras. His "South Indian Inscriptions," published between 1890 and 1893, gave in three volumes critical texts and translations of between three and four hundred inscriptions, mostly from the Tamil country. His reports on Sanskrit manuscripts in southern India were published in three massive parts between 1893 and 1905. His reputation as a scholar, however, will rest mainly on his edition of the edicts of Asoka—a subject on which he was the acknowledged authority. The publication of this standard work was delayed by the War, but it has recently been issued by the Indian Government on behalf of the Archæological Survey. In it the whole of the previous literature of the subject is critically examined, and each text is given in the original with an English translation. Hultzsch was a contributor to the *Journal of the Royal Asiatic Society* and to that Society's prize publications, as well as to other orientalist periodicals, while in recent years he took a prominent part in the work of the German Oriental Society. Orientalists in Britain are particularly indebted to him for, first, the valuable collection of Sanskrit and other manuscripts made during his stay in India which is now in the Bodleian Library at Oxford, and, secondly, for his exertions in securing the return to the India Office and the Royal Asiatic Society of the valuable manuscripts and books on loan at the Leipzig exhibition when the War broke out.

We regret to announce the following deaths:

Sir George Greenhill, F.R.S., formerly professor of mathematics in the Artillery College, Woolwich, on Feb. 10, aged seventy-nine years.

Dr. C. D. Walcott, secretary of the Smithsonian Institution of Washington, D.C., since 1907 and formerly director of the U.S. Geological Survey, on Feb. 8, aged seventy-six years.

News and Views.

Greek philosophers twenty-five centuries ago held that the gods work by geometry and by arithmetic: mathematics is the corner-stone of the temple of science. During the past two years a remarkable development has taken place in theoretical physics through the application of mathematical methods to the problems of the quantum. The introduction of the new quantum mechanics associated with the names of Heisenberg and of Schrodinger, and the revival of interest in the spinning electron, bid fair to initiate a new era in quantum theory. It is a striking testimony to the powers of generalisation inherent in mathematics that the method of matrices, due originally to Cayley, has proved a useful weapon of attack in the hands of Born and Jordan. After a prolonged discussion of the relative merits of language and mathematics as elementary disciplines, Willard Gibbs is reported to have said: "Mathematics is a language." Unfortunately it is too frequently "a tongue not understanded of the people," and for that reason it is not now our usual custom to publish in Nature articles involving advanced and unfamiliar mathematical methods. The present stage of development is, however, exceptional, and as many of our readers are deeply interested in the new ideas, we have to some extent departed from precedent and are publishing certain articles by eminent authorities in which mathematical treatment is a necessity.

In our present issue Prof. C. G. Darwin discusses the nature of the electron; after pointing out certain difficulties which arise on the hypothesis of the spinning electron, he suggests that the electron should be regarded as a system of waves of a vector character though not transverse. In treating the electron as a vector wave, he finds himself faced with a difficulty which arose also in the work on the spinning electron. A factor 2 has to be introduced to obtain the requisite results, and Prof. Darwin suggests that the quadratic form of space-time wants amplifying in some way by terms of the third degree. Perhaps a guess may be hazarded that the difficulty arises from insufficient attention being paid to the possible existence of 'magnetism' as essential to the constitution of the fundamental units of electric charge. But whatever may be the final reading of the riddle, our readers will welcome the attempts which are now being made to solve these and other fundamental problems in atomic physics.

The Prince of Wales was the principal guest at the annual dinner of the Institution of Electrical Engineers on Feb. 10. In proposing the toast of the Institution he mentioned that after his presidential address to the British Association last year, Lord Balfour had expressed the hope that his year of office would be marked by some striking scientific achievement. This has now been accomplished. By the labours of the experts in Great Britain and the United States, the Atlantic has been finally bridged by radio telephony, and to-day anybody in Great Britain can—at a price—call up anybody in America whenever he cares. The Prince reminded his hearers that the scientific machine is always running quietly in the laboratory. Individual effort by itself will not keep this machine running smoothly. Were it not for the existence of our various scientific and technical institutions it might even come to a standstill. The Institution of Electrical Engineers bridges the great gulf between pure science and practical science. Electricians have given to the community electric light, power, and radio. Their inventions are known throughout the world and in every home at the present time. Great Britain would be in a very bad way if it did not back up inventions. We are perhaps a little too apt to be afraid of new things. Dr. Eccles, the president of the Institution, in replying, said that the Institution numbers nearly 18,000 members, and is in close touch with every electrical activity in the country. The signals from the radio station at Rugby are received all over the globe, and measurements show that they are the most powerful signals in the world. The Rugby station and the beam stations in Britain are in advance of foreign practice. Last year Englishmen laid in the Pacific the longest submarine cable in the world constructed with all the latest improvements. Col. Wilfred Ashley, the Minister of Transport, said that the Electricity Act caused members of the Government a good deal of trouble last year; one effect of the Act being before Parliament, however, is that the manufacturers of Great Britain exported £20,000,000 worth of goods overseas during its discussion.

The gold medal of the Royal Astronomical Society has this year been awarded to Prof. F. Schlesinger for his work on stellar parallaxes and the determination of star places and proper motions by photography. Dr. J. H. Jeans devoted his presidential address to the Society on Friday last, Feb. 11, to a survey of this subject. Prof. Schlesinger's work on parallax began very early in the century. At that time only about eighty stellar parallaxes had been determined, and many of them were very uncertain. He published an article with several valuable suggestions for the improvement of photographic determinations. The two most important points were: (1) The light of the parallax star must be equalised with that of the comparison stars; this can be done either by placing a semi-transparent screen over the lighter image, or preferably by rotating a circular disc, from which a sector has been cut out, in front of it; (2) in order to eliminate differential refraction depending on colour, all plates must be taken close to the meridian, and the measures made in the direction of Right Ascension. Prof. Schlesinger carried out these principles first at the Yerkes Observatory, and later at Allegheny. He himself has obtained several hundreds of parallaxes, with probable errors in the neighbourhood of one-hundredth of a second of arc; many observatories, including Greenwich, have followed in his footsteps, so that the number of known parallaxes runs into thousands.

Another line in which Prof. Schlesinger has done most useful work is the application of doublet lenses to stellar photography. He has shown that accurate stellar positions can be obtained on plates covering an area of 5° × 5°; in spite of the smaller scale, the precision of the measures is practically equal to that obtained with the astrographic telescopes, while the area of the plates is six times as great. He has already published catalogues for two complete zones, and the results are so successful that the Astronomische Gesellschaft has made arrangements to survey the whole of the northern heavens in a similar manner in the course of the next few years. Prof. Schlesinger is now director of the Yale Observatory; he is continuing work on the lines that he followed at Allegheny, and visited Johannesburg early in 1925 to inaugurate the work of the telescope that was sent there from Yale, which is in charge of Dr. Alden.

Homage was rendered to the memory of the late Prof. Heike Kamerlingh Onnes on Feb. 10, when Prof. Ernst Cohen, of the University of Utrecht, delivered the Kamerlingh Onnes Memorial Lecture before the Chemical Society. The address was a panoramic survey of a fruitful life rather than an analysis of the theoretical and experimental achievements which entitle their author to be numbered among the *primi inter pares* for all time. Prof. Cohen first referred to the records of Kamerlingh Onnes' schooldays under Van Bemmelen, later professor of chemistry in the University of Leyden; to the award at eighteen years of age of a gold medal for an essay on "A critical investigation of the methods of determining the vapour density, and of the results obtained thereby, with respect to the relation of the nature of the chemical compounds and the density of their vapours"; to his sojourn at Heidelberg with Bunsen and Kirchhoff; and also to his sterling personal qualities. Onnes' doctorate thesis, presented at Groningen in July 1879, insisted on the closest correlation between theory and experiment, a programme to which he adhered to the end of his days. In Oct. 1882, when assistant in Bosscha's laboratory, he was appointed to succeed Ryke as professor of experimental physics at Leyden; simultaneously there commenced his triumphal progress through the realms of low temperatures.

Of Dewar and other workers in the same domain, "le gentleman du zéro absolu" with "Inferior!" as his watchword, continually spoke in appreciative recognition; neither did he neglect to acknowledge the part which his wife (Elisabeth Byleveld, whom he married in 1887) had played in his success by her care for her delicate husband. On Dec. 10, 1913, he received the Nobel Prize at the hands of the King of Sweden. In speaking of Onnes' character as a man and as an investigator, the lecturer referred to the report of the solidification of helium in March 1908, quickly followed by letters to Nature in April (vol. 77, pp. 559 and 581) withdrawing the announcement and ascribing the observations to solution phenomena of solid hydrogen in gaseous helium renewed experiments yielded liquid helium in the following July. In 1922 Onnes considered it safe to say that "the lowest temperature yet attained is some hundredths of a degree below 0·9° Abs." On Feb. 21, 1926, he passed away, leaving the last stage of his work on helium to be completed, but a few months afterwards, by Keesom. Prof. Cohen briefly referred to Onnes' services to the craft of instrument making, and concluded his tribute with words borrowed from Prof. Donnan: "He was a gentleman in every sense of the word, and one of the first gentlemen of European Science."

Believers in democratic institutions will watch with great interest the development of the Fundamentalist controversy in the United States, which is far from being the Gilbertian drama which it is sometimes taken for in England. The dictatorship of the uneducated and mentally undeveloped is a very real menace in the middle western and southern States of the Union. We have received a pamphlet, "Evolution and Intellectual Freedom," compiled by the Rev. Dr. Hay Watson Smith, pastor of the Second Presbyterian Church in Little Rock, Arkansas, in view of a threat to prohibit the teaching of the theory of evolution in the tax-supported schools of the State. The pamphlet contains a number of representative pronouncements of American and British men of science, as well as expressions of opinion by Theodore Roosevelt and Woodrow Wilson. In all probability these authoritative utterances will enliven the virulence of the anti-evolution fanatics; for if the doctrine is so well supported, there is all the more need to suppress it. How the fight will end it is impossible to say. Truth prevails, of course, but only with the intelligent, who must be in a very small minority in the State of Arkansas. We cordially admire the courage and vigour of Dr. Hay Watson Smith, and the ability displayed in this compilation of his. It is always so easy to fall in with the majority, and so difficult, in a country like America, where opinion is so much less free than in Europe, to take an independent line.

That Dr. Hay Watson Smith's pamphlet has not yet been effective is evident from a message in the *Times* of Feb. 11, in which its New York correspondent reports that the Arkansas House of Representatives has just passed a Bill prohibiting the teaching of evolution in any school supported by taxation. The Bill indeed passed by a narrow majority, 50 votes to 47, and had actually been defeated on a first roll-call. A similar Bill was 'killed' in committee by the New Hampshire legislation and by that of Missouri. In Louisiana, however, in spite of an adverse vote by the legislature, the Superintendent of Schools has, on his own authority, acting under pressure from religious associations, directed that evolution shall not be taught in State-supported schools. One wonders whether the science teachers are sufficiently well organised to resist this sort of dictation. Obviously, argument and appeals to reason are likely to be in effective, and only co-operative action, whether by passive resistance or otherwise, can avail. Yet the Fundamentalists are one of the most powerful, as they are the most ignorant, sections of opinion in America. Science teachers and, indeed, all who desire progress, will, therefore, have to exert themselves very actively if they are to survive in this struggle for free intellectual existence.

In his fourth Gifford lecture in the University of Edinburgh, delivered on Feb. 11, Prof. A. S. Eddington discussed the extension of the theory of relativity to non-uniform motion made by Einstein in 1915, ten years after the announcement of his earlier hypothesis. Prof. Eddington described the curious effects which would be observed when performing simple experiments within a freely falling lift, and the different views as to the results which observers inside and outside the lift respectively would record. Their experiences necessitate the re-formulation of the law of gravitation to include some conception of curvature. Space-time is now regarded as a four-dimensional manifold, and it requires twenty distinct measures at each point to specify it. Ten of these measures are more prominent than the rest, and Einstein's law of gravitation asserts that in empty space these ten principal measures of curvature are zero. A fundamental point in the theory is the relativity of acceleration.

Mr. W. H. Brown, Mill Hill School, London, N.W.7, recorded in last week's issue (p. 238) that two-way communication had been established between the School and the two Norwegian whalers *Sir James Clark Ross*, call-sign AQE, and the *C. A. Larsen*, call-sign ARDI. He now informs us that Mr. C. W. Goyder listened-in from the Mill Hill School station 2SZ) at 8.15 A.M. on Feb. 13, when he found that AQE was already in communication, in Norwegian, with LAIX (J. O. Berven, Stavanger). In reply to various questions, AQE reported to LAIX that signals were being received well, and that the ship had been in direct communication with LGN (the Bergen Radio Coast station) during the week. Mr. Goyder has heard another English station, 2LZ (F. A. Mayer, Stileman's, Wickford), in two-way communication with ARDI. It appears, therefore, that such communication with two ships in the Antarctic has now been established between two Norwegian and two English stations.

Dr. E. F. Armstrong, managing director of the British Dyestuffs Corporation, in his address before the Royal Society of Arts on Feb. 9 on "The Romance of the Organic Chemical Industry," selected the aliphatic alcohols as providing examples of chemical achievement of great industrial importance. Ethyl alcohol, used as a solvent and as an anti-freezing agent in the radiators of motor-cars, is made in large quantities from molasses. Its manufacture by an alternative method, the conversion of cellulose, for example, sawdust into fermentable sugar, Dr. Armstrong described as one of the prime problems of chemical industry to-day. By the synthetic production of methyl alcohol the cost has been reduced to about 20 per cent. of what it used to be. In due course the way is clear to cheaper formaldehyde and consequently cheaper indigo and synthetic resins. Butyl alcohol is being made in thousands of tons from grain or rice; but another process is also in use, based on acetylene. Yet another potential source is petroleum. In general, the tendency in the production of alcohols is to substitute methods based on coal or carbide for fermentation processes using food-stuffs. Dr. Armstrong concluded an interesting address with an appeal for more research directed to finding out how to accomplish new things, or even old things in a novel manner.

Prof. Edmund Gardner delivered a lecture on Feb. 8 on "Conceptions of the Cosmos, according to Dante," in continuation of the series which is being given at Bedford College for Women (University of London). He stated that Dante's cosmology is based ultimately on Aristotle, but as modified by Christian conceptions of the relationship of the universe to its First Cause. His individuality lies in his mystical interpretation of generally received theories. In Nature, "the Art of God," the soul may contemplate the working of the Divine Will. It has a threefold existence, in the mind of the First Mover, in the heavens, in the world of created things. The earth lies at the centre of the universe, disposed in nine concentric spheres revolving round it. Universal Nature originates in the ninth sphere, that of the First Mover, which by its motion regulates the motions of the other eight spheres. Enveloping the whole is the tenth sphere, or Empyrean, where there is neither time, space, nor natural law. The universe is brought into being by a process of double creation. The angels, the soul of man, the heavens are created immediately; secondarily, through the agency of Nature, there is a continuous process of generation by which potential matter becomes actual existence. The four elements, fire, air, water, earth, are disposed in concentric circles, earth being at the centre. But because universal Nature required a place where the elements could meet in order that things might come into specific being, portions of earth have been raised above the water. This, the inhabited earth, is confined to the northern hemisphere, and Jerusalem is its centre. At the antipodes lies the Mountain of Purgatory. The informative virtue of the heavens in the motion of the spheres superimposes form on the substratum of primal matter. The imperfect result is due not to the agent, but to a flaw in the material owing to the mysterious presence of evil. The whole creation is a single order through the working of a spiritual law of gravitation. An instinct is given to each thing to realise the degree of perfection of which it is capable, and to move to its own place where it is at rest. All causes are traceable to the First Cause; the universe is a unity.

Every one who has studied mechanics has a wholesome dread of high-speed machinery. In a 25,000 horse-power electric generator driven by a water or steam turbine and running at 3000 revolutions per minute, the rotating part weighs about 20 tons and the kinetic energy is about 50,000 foot tons. In fact, the energy is approximately the same as that developed by a head-on crash between two fourteen coach six hundred ton trains each travelling at 35 miles per hour. The bursting of a rotor running at this speed might well cause a serious loss of life as well as great damage to property. In practice the stresses are all computed beforehand and a large factor of safety is allowed. Only the highest class material is used, and the greatest possible care is taken in manufacture. In addition, the completed machine is usually tested in an underground pit. The Metropolitan Vickers Electrical Co. of Manchester has recently designed and erected a new ‘overspeed’ test house in which ‘rotors’ up to 14 ft. 6 ins. in diameter and shafts up to 40 ft. in length can be tested. The walls are 9 ft. 6 ins. thick and are composed of wood, steel, bags of sand, air-cushioning space, and reinforced concrete. In arranging the materials, advantage was taken of the lessons learned during the War in the construction of shell-resisting structures: the door alone weighs 17 tons. A motor of 1800 horse-power is installed permanently, and by suitable gearing, speeds ranging from 350 rev. to 7200 rev. per min. can be attained. Special arrangements can also be made to attain much higher speeds. When the rotor to be tested is fixed in position, the door of the test-house is closed and complete control is obtained by electrical means. Vibrographs, oscilloscopes, and high-speed cameras are employed and elaborate records are made. In addition, a hole is bored right through the centre of the shaft and the internal surface is carefully inspected by a specially designed telescope.

During the oceanographical expedition of the *Arcturus* in July 1925, a Petersen trawl was worked on the edge of the Challenger Bank (about 10 miles south-west from Bermuda), and at a depth of about 506 fathoms, in a region where the sea bottom rapidly slopes down to more than 2000 fathoms. In the catch made were four eggs of about 3·3 mm. in diameter. Their appearance was that of the eggs of eel-fishes that are known, but there was only one way of identifying the species to which they belonged—that of hatching them out. Fortunately this was successfully done, and in a preliminary note (*Science*, Nov. 5, 1926) Marie Poland Fish describes the larvæ that were so obtained. There seems to be little doubt that they are leptocephali of the American eel, *Anguilla rostrata*. Pelagic nets were being worked both at the surface and at various depths, while the Petersen trawl was at the bottom, but only in the latter instrument were eel-eggs obtained. It is suggested by the author that the observations favour the previous theory of deep fertilisation. The catch was made within the boundary of the region regarded by Johs. Schmidt as the breeding ground of the American and European eels. Few observations will give naturalists so much pleasure as this: since 1904, Dr. Schmidt has carried on his intensive study of the life-history of the eel, and a year ago the only essential observation that had still to be made was that o finding the eggs. Details are yet to be worked out but with this record there ends a mystery that ha perplexed naturalists since the time of Aristotle, an a word of congratulation to Marie Fish and Johs Schmidt is not inappropriate.

The sixth annual report of the British Electrica and Allied Industries Research Association, presente at the meeting on Feb. 11, is of interest, as it show that electrical manufacturers are keenly alive to th importance of scientific research. As a rule th research work undertaken by private firms is confine to that which yields immediate results commercially But there is a large section of the work which demand intensive co-operative effort on the part of all section of the industry, and in this direction research associations can do useful work. During the past year a attempt has been made to unravel the complicate physical phenomena which cause the breakdown o electrical insulation. Considerable progress has bee made in explaining the phenomena as shown by gases and it is hoped that the vexed questions of the breakdowns in liquids and solids will soon be satisfactoril answered. In particular a study of the coron phenomena in liquids is furnishing data of importanc to designers. Working pressures are still on th upward grade and accurate and simple methods o measurement are required. A useful critical résum of recent work on dielectrics has been prepared b Mr. L. Hartshorn of the National Physical Laboratory Enlarged tables have been issued during the yea based on the experimental work previously complete by Prof. H. L. Callendar. The work has been extende to higher temperatures and pressures and the apparatu constructed is expected to give results up to a temperature of about 850° F. and steam pressures o about 3000 lb. per square inch. The results give have proved useful to the designer and form a trustworthy basis for the rating of turbines.

The formation of Imperial Chemical Industries Ltd., a combination of four of the most importan chemical concerns in Great Britain, namely, Brunne Mond and Co., Ltd., Nobel Industries, Ltd., Britis Dyestuffs Corporation, and United Alkali Co., Ltd. is of high significance in its bearing upon chemica research in Great Britain. The larger an industria corporation grows, the more time can it afford t spend on research of an academic nature, because it results are available to a larger public. It is commo knowledge that some of the constituent firms of th above combination have already made substantia contributions towards the discovery of new knowledge of a general type, and the advances made i this direction are an earnest of substantial contributions from industry to science to be expected in th future. Most research work in chemistry carried o at universities and similar institutions is limited t conditions of easily obtainable temperatures an pressures, on account of lack of money, lack o continuity of research staff, and the necessity o doing research which will ‘come out’ in a reasonabl time.

A great combine such as Imperial Chemical Industries, however, has great advantages: it is endowed with ample funds, has plenty of time and a continuity of staff, and is therefore able to attack problems which are beyond the scope of most universities. Whether the results of such work will be suitable for publication, and whether it will be published, remains to be seen. Much scientific research of this kind is concerned with the determination of as many physical constants as possible, because they can be applied later to other problems. That these determinations will be carried out with the greatest accuracy possible is also certain, in order to make the work permanent and of real capital value. We may be sure, therefore, that the well-known research tendencies of some of the constituent companies will be intensified in the allied group. The effect of this on academic life will be all to the good, and the study of the theoretical sides of somewhat neglected branches of science will be promoted. In short, it is not too much to hope that the effect of the research policy and publications of the new combine will give to academic chemistry a healthy stimulus and direction which should be of benefit to both science and industry.

It is some twenty years since the New Zealand government began its policy of acquiring lands for the sake of preserving natural scenery. From a small beginning the area of scenic reservations in the Dominion has now grown to 454,000 acres. The recent annual report of the Department of Lands and Survey on scenery preservation records the addition during 1925–26 of 3067 acres. These include an area surrounding the Wairoa Falls which will ensure the safety of the falls and a stretch of native bush; a kauri forest of 652 acres on the Waitakerei ranges, where bird life is abundant; an area of 19 acres of the limestone rocks of Waro; and several other areas valuable on account of their wild life or proximity to well-settled districts. Part of Motuanaura Island on Queen Charlotte Sound was reserved on account of its historic interest, since it was there that Captain Cook in 1770 proclaimed British sovereignty over the South Island.

The Smithsonian Institution, Washington, has just received from M. Ferdinand Canu, of Versailles, a leading authority on fossil micro-organisms, his collection of fossil invertebrates from France, and particularly the Paris basin, that he has spent fifty years in gathering together. The collection is accurately labelled as to the localities and geological horizons whence the specimens came. M. Canu chose the Smithsonian as the depository of his collection to secure its preservation and to insure its immediate use in connexion with the recently discovered relationship between fossil micro-organisms and oil deposits, a field in which associates of the Smithsonian Institution were among the pioneers. M. Canu made the gift through Dr. R. S. Bassler, palæontologist of the National Museum under the Smithsonian, with whom he has collaborated extensively since 1910 in working out geological horizons for the Atlantic and Gulf States. This work was undertaken by Dr. Bassler and M. Canu at the request of the U.S. Geological Survey. In 1924 M. Canu received the Elliot medal, one of the highest honours in American science, from the National Academy of Sciences for his work in palæontology.

With the December number our Norwegian contemporary *Naturen* completed its fiftieth year. A retrospect of the valuable popularising work it has accomplished since its foundation in 1876 by the geologist, Dr. Hans Reusch, is given by Dr. W. C. Brøgger. The number also contains an article by Lektor O. Valeur on the theory of relativity and its effect on our conception of the universe. Continuing his articles on the food of the East, Dr. Sopp here describes *ching-tong*, a Chinese malt-extract prepared from rice and used for many dietetic purposes. A note on lemming, by J. Grieg, and other small notes complete the number. We offer our congratulations and best wishes for the future to the present editorial staff.

The Report of the Bristol Museum for the year ending Sept. 30, 1926, records the gift by Lord Ducie of the collections formed at Tortworth Court by the third Earl of Ducie. These include a unique fauna from the Llandovery and Wenlock rocks of Tortworth, with good series from the older rocks of South Wales and the Carboniferous Limestone of Belgium, also more than two thousand stone implements from the British Isles and Europe, and ethnological specimens from New Guinea and North America. Another important accession is the collection of birds and mammals obtained by Sir J. H. Greville Smyth, Bart., preserved at Ashton Court and in the Bungalow, Ashton Park, and now presented by the Hon. Mrs. Esmé Smyth. It is expected that the extension of the Museum and Art Gallery, provided for by the generosity of Sir George A. Wills, Bart., will be completed in two years.

In the Report of the Executive Committee of the Empire Cotton Growing Corporation, submitted on Jan. 13, mention is made of the Report of the Research Sub-Committee set up by the Imperial Conference, which, after referring in eulogistic terms to the work of the Corporation, recommended the Conference to pass a resolution commending to the various Governments the work of the Corporation in the promotion of Empire cotton-growing. It also recommended periodical agricultural conferences, the first to be in London in 1927, and invited all the Governments concerned to send representatives. The Director of the Corporation is about to start upon a visit to South Africa, where, under plantation conditions, the present low price of cotton is a serious handicap. Rain-grown cotton is being successfully extended in the Sudan, and notice is taken of successful work going on in many parts of Africa, especially of Mr. Sampson's activities in work upon rotation of crops, a thing which is eminently desirable in connexion with Empire cotton.

The Société de Biogéographie, Paris (61 rue de Buffon), is now entering into the fourth year of its existence and we are asked to invite the attention of all botanists, biologists, ethnologists, geologists and zoologists, whose aim is the study of the distribution of living and fossil organisms over the surface of the globe, to this association. The society meets every month, and useful and interesting discussions on various subjects are held. In addition, at fixed intervals it institutes fundamental investigations on subjects selected as of importance to biogeographers, the solutions of which may require the collaboration of specialists in various branches of knowledge; for example, a series of memoirs forming a volume of 250 pages has lately been prepared on the "Histoire du Peuplement de la Corse"; a new volume on "Le Peuplement des Montagnes" is in preparation. The number of the members of the society is limited; but its reports (*Compte rendu Sommaire des Séances de la Société de Biogéographie*) for the years 1924–26 are on sale; current reports can be subscribed for (15 francs a year for France and 18 francs for abroad).

The new journal *Protoplasma* or the *International Journal of the Physical Chemistry of Protoplasm*, which has recently been founded in Austria under the editorship of Prof. Weber of Graz and Prof. Spek of Heidelberg, seems to be thoroughly justifying its existence. There has certainly not been, up to the present time, any journal devoted to the physics and chemistry of the cell-interior—to physico-chemical cytology. In the first number, W. Seifriz investigates the protoplasmic papillæ on the surface of the immature sea-urchin egg and discusses their colloidal nature. E. Küster writes on plasmolysis and gives details of his experiments on *Vakuolenzerklüftung*, and much the same subject is treated by W. Beck, who deals with sucrose and nitric acid as plasmolysing agents. B. Ephrussi has a very interesting paper on the temperature coefficients of the different phases of the mitosis of the sea-urchin egg, which he compares with others previously determined for the cleavage of Ascaris eggs. J. Gicklhorn's review deals with the importance of the dielectric constant in microbiology. Two bibliographies are given, one on recent work with ray effects on protoplasm, and the other with the viscosity of protoplasm, and the number is very well illustrated. The second number contains papers by F. Vonwiller on microscopical technique, G. W. Scarth on permeability in Spirogyra, and M. M. Brooks, also on cell-permeability. A. Rumjantzeff and B. Kedroffski contribute a paper with some beautiful plates on vital staining in protozoa, Y. Kuwada and T. Sakamura another on the colloidal chemistry of chromosomes, and G. Ettisch and A. Szegvari a third on the structure of connective tissue fibrils. Finally, there is a review by J. Needham and D. M. Needham on the oxidation-reduction potential of the cell-interior. In both issues there are a valuable series of reviews of books, and abstracts of the more important current original investigations. Without a doubt the new journal will fill a distinct gap in scientific periodical literature.

At the annual general meeting of the Royal Astronomical Society, held on Feb. 11, the following officers were elected: *President*, Rev. T. E. R. Phillips; *Vice-Presidents*, Sir Frank Dyson, Prof. A. S. Eddington, Prof. A. Fowler, and Lieut.-Col. F. J. M. Stratton; *Treasurer*, Mr. P. H. Hepburn; *Secretaries*, Dr. J. Jackson and Dr. H. Knox-Shaw; *Foreign Secretary*, Prof. H. H. Turner.

At the meeting of the Royal Microscopical Society held on Jan. 19, the following officers were elected: *President*, Dr. J. A. Murray; *Vice-Presidents*, Mr. A. Chaston Chapman, Dr. C. Da Fano, Dr. J. W. H. Eyre, The Hon. Sir Charles Parsons; *Treasurer*, Mr. C. F. Hill; *Secretaries*, Mr. J. E. Barnard, Dr. Clarence Tierney; *New Members of Council*, Mr. J. G. Bradbury, Dr. W. E. Cooke, Mr. M. T. Denne, Dr. J. C. Mottram; *Librarian*, Mr. S. C. Akehurst; *Curator of Instruments*, Mr. W. E. Watson Baker; *Curator of Slides*, Mr. E. J. Sheppard.

The annual general meeting of the Institute of Metals will be held on Mar. 9 and 10 in the hall of the Institution of Mechanical Engineers. The first morning will be devoted to papers on the effect of arsenic and bismuth on the properties of copper, and the afternoon to a paper on electric furnaces in non-ferrous metallurgy; the papers for the morning of Mar. 10 deal with the penetration of solders and the study of eutectic alloys, and those for the afternoon with magnesium, aluminium, and other alloys, and early brass and lead. The annual dinner will be held on the evening of Mar. 9.

A useful adjunct to the botanical teaching in the schools of Reading has been provided by Dr. J. B. Hurry, who has presented a well-stocked economic botany collection, which has been organised as a department of the general museum of the borough. The specimens are classified into: miscellaneous food products, nuts, fibres, woods, gums and resins, medicines, and dyes. Pupils will thus be enabled to turn aside for a space from the more academic aspects of botany and study a branch of the subject too often neglected in schools—the origin and production of some of the common substances of domestic and industrial usefulness.

The latest catalogue (No. 491) of Mr. F. Edwards, 83A Marylebone Road, W.1, should be of great interest to many readers. It gives the titles, and in some cases particulars, of upwards of 1600 works relating to the origin and history of man, classified under the headings of anthropology, etc., Buddha and Buddhism, folklore, freemasonry, gipsies, and witches and witchcraft. The catalogue can be obtained free upon application to the bookseller.

The Section of Terrestrial Magnetism of the International Union for Geodesy and Geophysics has issued a "Preliminary Report on Subjects of Investigation." The matters discussed include comparisons of magnetic instruments (L. A. Bauer), magnetic characterisation of days (A. Crichton Mitchell), terminology in terrestrial magnetism and electricity (C. Maurain), the measurement of sudden commencements of magnetic storms (A. Tanakadate), the study of magnetic rocks *in situ* and in the laboratory (L. Palazzo), crucial phenomena of polar lights (C. Størmer), and thunderbolts (E. Mathias).

We have received "A Guide to British Spas and Climatic Health Resorts," 1927, which is published by Messrs. J. and A. Churchill, 7 Great Marlborough Street, W. (1*s*. net). Detailed information is given of the situation, climate, bath establishments, and characters of the waters of the British spas, and of the class of cases likely to be benefited thereby. Information is also given respecting the principal British health resorts other than spas. Lists of hotels, hydros, and other residential accommodation are included.

Applications are invited for the following appointments, on or before the dates mentioned:—A lecturer in building trades at the East London Technical College, Cape Province—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W.C.2 (Feb. 21). A junior scientific officer under the Directorate of Scientific Research of the Air Ministry—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants (Mar. 9, quoting A. 107). A director of cancer research in the University of Sydney—The Agent-General for New South Wales, Australia House, Strand, W.C.2 (May 16). A research assistant, with qualifications in physical chemistry, at the Huddersfield Technical College—H. H. Gray, Department of Chemistry, Technical College, Huddersfield. An instrument maker, preferably with electrical and optical training—The Secretary, Experimental Department, Fine Cotton Spinners' and Doublers' Association, Ltd., Rock Bank, Bollington, nr. Macclesfield.

Erratum.—Prof. H. S. Allen points out that in his letter in Nature of Feb. 12, p. 237, on "Spinning Electrons and Protons," the late Prof. McLaren's initials, correctly given by him, were printed as "G. B." Prof. McLaren's Christian names were Samuel Bruce.

Our Astronomical Column.

The Comas Sola quickly moving Asteroid.—This object was at first reported as of doubtful nature, comet or asteroid. It is now assigned to the latter class, with designation 1927 AA.

Dr. A. C. D. Crommelin has obtained the following orbit from observations extending from Jan. 10 to Jan. 24:

$$\begin{array}{rl}
T = & 1926,\ \text{Sept. } 21{\cdot}7559\ \text{U.T.} \\
\left.\begin{array}{r} \omega = \\ \Omega = \\ i = \end{array}\right. & \left.\begin{array}{rrr} 147^\circ & 25' & 14{\cdot}2'' \\ 279 & 4 & 15{\cdot}9 \\ 24 & 47 & 58{\cdot}7 \end{array}\right\} 1927{\cdot}0 \\
\phi = & \begin{array}{rrr} 16 & 8 & 18{\cdot}3 \end{array} \\
\log q = & 0{\cdot}229249 \\
\text{Period} = & 3{\cdot}5977\ \text{years.}
\end{array}$$

The orbit is of the Aethra type. The inclination is high, but much less than that of Pallas. The planet is receding from earth and sun, so its light will diminish.

A similar but somewhat brighter object is reported by Mr. Oikawa of Tokyo. It is some 20° farther north than that of Prof. Comas Sola, but has the same daily motion, $-1^{\text{m}}\ 24^{\text{s}}$, south 17′. Its magnitude is 11.

The Planet Neptune.—Mr. M. E. J. Gheury de Bray writes: "Neptune is exceptionally well placed for observation now. Any one can pick it up readily with an opera-glass magnifying two or three times. Pointing the binoculars to α Leonis (Regulus), the next star in the field in order of brightness, on the right, is ν Leonis. The next object in the field in order of brightness after ν Leonis is a little above this star and on the right. This object is Neptune. A small telescope will show other stars which may lead astray the inexperienced person. An opera-glass will only show these three objects—Regulus, ν Leonis, and Neptune, the last being the faintest of the three, so that it can be picked up in this way with the greatest ease. It is moving west and will soon approach other stars, and will then be less easy to identify, so it should be looked for now."

Sunspot Frequencies and Terrestrial Phenomena.—An interesting paper (*Journal of the College of Science*, Imperial University, Tokyo, vol. 44, Art. 6) by Prof. T. Terada has recently been received which bears the title "On Some Remarkable Relations Between the Yearly Variations of Terrestrial Phenomena and Solar Activities." The association of earthquakes with spot frequencies in the north- and south hemispheres of the sun, called *N* and *S*, is examined, and Terada finds that for some places in Japan and Jamaica, minima of earthquake frequency occur in years when $N-S$ is small, while for others, maxima occur under these conditions: some places show neither feature. Relationships with *N* and *S* are also found for the data of pressure and temperature for a network of stations over the world. The pressure associations resemble those for earthquakes; but the classification for temperature is more complex, and we have in addition one type in which maxima occur both with small and large values of $(N-S)/(N+S)$, minima occurring with intermediate values; while in another type maxima and minima have interchanged places. The paper contains much that is suggestive, and doubtless many of the results indicated are true. But there is no fixed criterion for a maximum or minimum, so that two workers may differ in their selection of these critical points; and, as Terada's statements of relationship have in most cases neither a diagram nor a numerical statement in the paper to support them, some readers will wish for the ordinary methods of correlation with their definite statement of results and their comparison with what can be expected from the working of pure chance. The idea that important geophysical phenomena depend on the difference of the sun's activities in the northern and southern hemispheres is so important that Prof. Terada's future papers will be awaited with much interest.

The Observer's Handbook for 1927 (Royal Astronomical Society of Canada).—This book contains much matter of use to observers. Besides the usual ephemerides there are maps showing the tracks of the planets among the stars. Both Jupiter and Uranus come to the north of the equator this year, after being south of it for 6 and 42 years respectively. They will be near each other in July. The period of Jupiter IX. is erroneously given as 3 years; it should be 745 days. There is a very useful table giving positions, magnitudes (apparent and absolute), spectral type, parallax, proper motion and radial velocity of a considerable number of stars.

Research Items.

ORIENTAL SEALS.—Mr. I. M. Casanowicz has issued, in vol. 60 of the *Proceedings of the U.S. National Museum*, an illustrated descriptive catalogue of a selection of the ancient oriental seals in the Museum. The collection consists of about 90 originals with flat plaster casts made from them and upwards of 200 casts of seals lent by private owners to the Museum for the purpose of making casts from them in the laboratories. The selection has been made with the view of showing a representative series of the artistic types and the mythological subjects of the seals. They come for the most part from Mesopotamia and Asia Minor and in date range from the early Babylonian to the Persian period.

PHYSICAL TYPES AND CULTURES IN AMERICA.—In Part 3, vol. 65, of the *Proceedings of the American Philosophical Society*, Dr. Aleš Hrdlička puts forward an answer to the problem, frequently propounded, of the relation of physical type to type of culture in America. The main pre-Columbian cultures are: The Moundbuilders and the Pueblos in the United States; the Toltecs, Aztecs, and Mayas in Mexico and Central America; and the Chibcha, Chimu, Nascas, Kechua, and Aymara in South America. There is no physical proof of the impact of accessions from outside which influenced any of these cultures. So far as is known, the peoples of these cultures were just Indian and nothing more. Any contact there may have been was so small as to leave no physical trace. Resemblances to other peoples, *e.g.* those accepted by Quatrefages, Ten Kate, Rivet, and Sullivan, which were held to point to Australian and Melanesian admixture, are either due to old basic relationship or individual variations which are no proof of racial admixture. The pre-Columbian Indians, however, were not all of one type. There were at least four main types: (1) Older dolichocephals—many of the tribes from South America to Mexico and California; (2) older brachycephals (Toltec type), Central America and Ecuador down the coasts of Peru to North Arica; (3) later dolichocephals—Algonkin and most Iroquois; (4) the later brachycephals—Athapascan tribes on the west coast from Alaska to North Mexico. Relating skull form to culture we find the Moundbuilders were partly Toltec, partly Algonkin; the Pueblos are mostly dolichoid, with here and there a strong dominant element of older brachycephals. The old Aztecs were a branch of the older dolichocephals, but the Aztecs of the Empire were a conglomerate: the Mayas were a pure sub-type of the older brachycephals. The Incas were also a conglomerate: the coast people were of Maya type; the mountain peoples old dolichoids. It appears that it is the older brachycephalic type which has developed the higher cultures; but the Aztecs, Aymara, most of the Pueblos, and the main element of the Kechua were of the older dolichoid type. The newer dolichoids give the Iroquois with their relatively high culture, and the newer brachycephals are responsible for some of the cultures of the north-west coast. There appears, then, no special connexion between the cultures and the physical type of the Indian.

COURTSHIP IN SPIDERS.—In three recent papers (*Ann. Mag Nat. Hist.*, 9. 18, 113; *Proc. Zoo. Soc.*, 1926, part 2, p. 318, and part 4, p. 1125) Mr. W. S. Bristowe and Mr. G. H. Locket have made some contribution to our understanding of the process of courtship in spiders. The keen-eyed wolf-spiders, Lycosidæ, have been seen waving their decorated legs and palpi before the female. It is suggested that the males are made to begin their display by the scent of the females and that the scent organs are situated at the tips of the legs and palps. Crab-spiders, Thomisidæ, are less keen-sighted and caress the female by tickling her as they walk over her. Among web-spinning spiders courtship is carried out by vibration of threads of the web on which the male plays, and induces the female to come out from her retreat. Some species of female show no reluctance and this display is much reduced. Mr. Locket deals very ably with the popular ferocity of the female, and shows that while it may be the rule for some, with others a common life may occur. The authors see a dual purpose in these pre-coition activities, *recognition* and *stimulation*. The necessity of stimulating the female has long been pointed out by others, and to this is now added the necessity that the female shall recognise the male so as to distinguish him from edible prey. *Realisation* would be a better term than recognition, for a virgin female cannot recognise that of which she has no previous experience. Realisation may be produced by the same physiological changes which, continuing, result in eagerness or a state of stimulation, the 'two purposes' of courtship being, in fact, inseparable.

ANTARCTIC ECHINOIDEA.—The sea-urchins collected by the Australasian Antarctic Expedition (1911–1914) have now been reported on by Prof. R. Koehler. There are only 21 species and a variety. and they belong to 11 genera all previously known. The new forms are distributed in the following genera: Notocidaris, 1 species, 1 variety; Goniocidaris, 1 sp.; Sterechinus, 1 sp.; Echinosoma, 1 sp.; Pourtalesia, 2 spp.; Abatus, 1 sp.; Antipneustes, 4 spp. *Goniocidaris impressa* n., from Maria Id., *Notechinus novae-zealandiae* Mortensen, from Macquarie Is., and *Echinosoma australe* n., from 35° S. 135° E., are not Antarctic. The discovery off Adélie Land of *Abatus cavernosus* (Philippi), *A. shackletoni* Koehler, and *Pseudabatus nimrodi* Koehler, considerably extends the known range of those species. Antipneustes is a name that replaces Amphipneustes Koehler 1901 to avoid confusion with the unknown Amphipneustes Wiegmann 1837; some of the species are remarkable for the size of the brood-pouches in the female. It is unfortunate that the young individuals contained in some of the pouches were not preserved well enough for study. Indeed the harvest of echinoids, especially among the more interesting but fragile heart-urchins, would have been much richer had it not been for careless packing. The report ends with a complete list of the eleutherozoic echinoderms found up till now in the antarctic and subantarctic regions.

MARINE CRUSTACEA OF THE ANTARCTIC.—The Commission dealing with the scientific results of the Belgian Antarctic Expedition has just issued a report on the Edriophthalma ("Rés. Voyage de la *Belgica* en 1897-99," Zoologie, Tanaidacés, Isopodes, et Amphipodes. Anvers, 1926). The determination of the species was entrusted to Bonnier on the return of the expedition, but the work was interrupted by his death, and not until now, more than twenty years later, has it been possible to complete the examination of the material. As M. Th. Monod, who undertook the task, justly remarks, owing to this long delay in working out the results many of the species brought back by the *Belgica* were rediscovered and described by the later expeditions to the Polar seas—by the *Southern Cross, Français, Pourquoi Pas? Discovery, Terra Nova,* and *Gauss* in the Antarctic, and by the *Ingolf* in the Arctic. But although the publication of these various reports has considerably reduced the number of the *Belgica* species new to science, it has given M. Monod a unique opportunity of collating all the evidence on the geographical distribution of these polar forms. Taking the parallel of 60° S. as approximately the limit of the antarctic and subantarctic fauna, Monod enumerates 15 species of tanaids and 133 of isopods collected by the different expeditions, including the *Challenger*. 21 out of the 27 isopod species of the *Belgica* fall into this category, 8 of them taken by the *Belgica* alone—seven being new to science, and one, *Astacilloschus Ingolfi*, recorded also from the Arctic by Hansen. The isopods form the most important part of the collection. 2 tanaid species, 1 new, and 1 new amphipod are also recorded, together with 11 other species, including the ubiquitous *Jassa falcata* and *Leucothoe spinicarpa*. The new species are defined, and the paper is well illustrated throughout with careful detailed drawings.

Milk of the Monotreme.—Milk obtained from an echidna (*E. aculeata*) has been examined by Mr. Hedley R. Marston (*Australian Jour. of Exper. Biology and Med. Science*, vol. 3, pt. 4, Dec. 1926, p. 225). The specific gravity was 1·023. The proteins consisted of a casein with albumin and globulin. Carbohydrate was present as lactose. The fat was pure triolein, and glycerides of soluble volatile fatty acids were absent. The figures obtained were (per cent.): Total solids, 36·75; casein, 8·4; albumin and globulin, 2·9; lactose, 2·81; fat, 19·62. Compared with cow's and human milk, the total protein and the fat are both very high and the fat is peculiar, but the figures are approached by those of rabbit's milk, which contains 12·0 and 13 5 per cent. of total protein and fat respectively. The author remarks that either the young echidna must store fat during the lactating period, or must be endowed with an extraordinary power of oxidation of fatty acids, otherwise extreme acidosis would follow consumption of a diet so rich in fat.

Mollusc as Agent in the Sugar-cane Root Disease.—Dr. Paul Bartsch and Mary E. Quick have been studying the small snail which, by penetrating worm-burrows and feeding on the root of the sugar-cane in Louisiana, admits infection with resulting decay of the root (*Jour. Agric. Res.*, vol. 32). The authors have successfully identified this snail with the well-known and widely distributed little *Zonitoides arboreus* (Say). This is demonstrated by means of careful comparison of its detailed anatomy with that of specimens of *Zonitoides arboreus* taken from their normal habitat under decaying bark, where their food consists largely of mycelial threads of fungi. The little animals appear to be largely nocturnal in their habits. Excellent figures of the animal, its shell, and its anatomy are given.

Constitution of the Earth.—The latest issue (vol. 1, No. 8) of the *Geophysical Supplement* to the *Monthly Notices of the Royal Astronomical Society* is devoted entirely to seismology and geodynamics. One paper, by L. F. Richardson, is concerned with the design of vertical seismographs. H. H. Turner deals with the seismological observations of *P* and *S* for the five years 1918–1922, during which the times for *P* and *S* have been compared in the *International Seismological Summary* with the adopted tables of times; the comparisons are summarised and discussed for epicentral distances less than 120°. The paper raises several new questions which must be left for later investigation. The other two papers are by H. Jeffreys; in one he rediscusses the seismic disturbances which have been best observed at short distances, and concludes that the outer layers of the earth's crust consist of about 12 km. of granitic material above a basaltic layer about 25 km. thick. No further great change of material appears to occur down to a depth of about 1000 km. The velocities of compressional waves in the two outer layers are estimated at 5·6 km. and 6·2 km./sec., that in the sub-basic layer being 7 8 km./sec. His other paper deals with the viscosity of the earth; the lithosphere is shown to be practically non-plastic, while even in the rest of the rocky shell the time of relaxation is as high as two years. The forces tending to produce secular displacement of the earth's crust (chief among them being the equatorial drift) are incapable of causing important distortion of the lithosphere during geological time, but might give appreciable bodily displacement of the lithosphere over the interior. A region stripped of granitic material by the separation of the moon would probably persist. The viscosity found for the lower parts of the shell would not preclude convection currents.

Magmatic Differentiation.—A paper on the Katmai magmatic province, by C. N. Fenner (which appears as a supplement to the *Journ. Geol.* for Oct.-Nov. 1926), is a most notable recent contribution on the origin of igneous rocks. A large number of analyses of Katmai rocks has been made, and the variation diagram indicates an almost linear variation of the oxides over a wide range of silica percentages. It is shown that differentiation by the separation of successive crystalline phases gives a broken and scattered diagram of very different and more complex form. Presumably, therefore, this process has not operated to any appreciable extent in the evolution of the Katmai rocks. There is, indeed, no known process which is competent to provide a linear variation, though Dr. Fenner suggests that volatilisation as a transporting agent is more likely to fulfil the requirements than gravitational sinking of crystals or squeezing out of residual fluids. In the course of the paper the origin of micropegmatite and graphic intergrowths is discussed; the field evidence for differentiation in different classical regions is surveyed; and many examples of the indubitable action of volatile fluxes are described. It is concluded that the operation of a variety of processes is indicated, and that Bowen's scheme of crystallisation differentiation cannot be accepted as having anything approaching the almost universal applicability that has been claimed for it in recent years.

The Fracture of Quartz by Heat.—We have received from Mr. Bernard W. Holman a copy of a paper read by him before the Institution of Mining and Metallurgy on Jan. 20, on "Heat-treatment as an Agent in Rock-breaking," together with further photographs illustrating the paper. An examination of Roman and other ancient fire-workings shows that the fragments of quartz are mostly in the form of a granular sand, and not of angular cracked fragments, as would be obtained if a fire were built against the face and water used for quenching. The granules are often cubical. Laboratory experiments show that disintegration at the transformation point, 575° C., gives granules and not splinters. Gentle pressure on a correctly heat-treated specimen gives thin laths of silky transparent quartz, often with finely toothed edges. Quartz from different sources gives varying results, and some specimens become fragile even when quenched from 300°. Only a few varieties will give the silky laths, which are the most friable form of quartz. A change in the dielectric constant is observed at as low a temperature as 340°, and the temperature at which disintegration begins varies over a range of 20°. It is suggested that the results may have a bearing on the nature of the allotropy of quartz.

It should be noticed, however, that disintegration in quartz may occur at low temperatures through the expansion of gases and vapours contained in the cavities, the extent of the cracking depending on the rate of heating, and this fact may account for some of Mr. Holman's results, without assuming any allotropic change other than the well-known transformation at 575°.

The Creation of Matter.—At the meeting of the Mathematics and Natural Philosophy Section of the Academy of Sciences of Vienna on Dec. 16, a communication was received from Dr. Arthur Haas on the increase of frequency of light quanta which impinge on swiftly moving particles of matter. The quantum and the particle are supposed to move in opposite directions and the quantum on impact has its direction of motion reversed. In these circumstances, when the speed of the particle is of the order of the speed of light, the frequency of the quantum may be so raised that the quantum is converted into a proton doublet with a wave-length of 0·013 tenth metres. As an example, the case of a particle moving with half the speed of light may be taken. The frequency of the quantum is then trebled by the impact. The author points out that the above leads to the possibility of a cosmical reconstruction of matter out of light quanta.

The Scholes Bomb Calorimeter.—A bomb calorimeter of the type originally introduced by Berthelot, embodying a number of new mechanical features, and suitable for the determination of the calorific power of solid and liquid fuels, has been placed on the market by Messrs. G. Cussons, Ltd., of Manchester. The bomb body, cover, and most of the details of the calorimeter are made of stainless steel and are machined from the solid billet. A small spanner is employed to screw the cover-nut home, and the body and base are screwed together by hand. The cover of the bomb forms the base on which the bomb stands, and the ignition rods (one of which acts as a support for the crucible cradle) are attached to the base. A form of self-sealing rubber ring, which is isolated from the combustion zone, and has been found to remain in perfect condition after more than 200 determinations of calorific power, prevents escape of oxygen or products of combustion. Oxygen enters the bomb through a spring-loaded non-return valve and is discharged through a screw-down valve. The device obviates the necessity for a gland and stuffing-box. Attachment of the ignition wire to the ignition rods is effected by insertion of the wire in slots, in which it is secured by movable sleeves. The chamfered edge of the sleeves acts as a wire cutter, effecting economy of the nichrome wire used in firing the charge.

Radiographic Examination of Coal.—We have received a portable stereoscope and some stereoscopic X-ray photographs of coal, coke, and quartz, taken by Messrs. Kemp and Thomson, Technical Radiological Laboratory, 20 Laverockbank Road, Edinburgh. X-ray stereoscopy is, of course, very familiar in medical radiology, and its utilisation for the present purpose is of interest in providing another illustration of the uses of X-rays in industry. In the case of coal the photographs reveal the extent and distribution of the 'free' mineral ash of relatively high density. The authors have also applied X-ray methods to the study of the 'jig-washing' of coal, whereby the extraneous stony and shaly matter is mechanically separated out from the clean coal.

The Burning of Gases in Nitrous Oxide.—The scanty chemical literature relating to the burning of gases in nitrous oxide is considerably extended by the recent communication to the Mancheste Literary and Philosophical Society by Prof. H. B Dixon and W. F. Higgins, of the results of thei investigations of the burning of hydrogen, methane ethylene, propylene, and acetylene in nitrous oxide Davy's generalisation that combustible bodies require a higher temperature to ignite in nitrous oxide than they do in oxygen is not confirmed, all the gases tested having *lower* ignition points in the forme gas than in either oxygen or in air. These ignition points correspond with temperatures below that at which the thermal decomposition of nitrous oxide is appreciable. The length of a hydrogen flame is increased about twelve-fold and its diameter about two-fold when the air in which the gas burns is replaced by nitrous oxide. The spectrum of the flame in nitrous oxide is continuous from red to violet with the 'steam' lines well marked. The red tinge in the flame at ordinary pressures is due to the formation of nitrogen peroxide. The paper contains tables of the respective ignition points of hydrogen in nitrous oxide at pressures between 150 mm. and 1000 mm. of mercury, and of ethylene and propylene in nitrous oxide and oxygen at 150 mm.–1000 mm. pressures.

The Separation of Radioactive Substances.—J. Kendall, E. R. Jette, and W. West have published details of the application of ionic migration methods to the separation of mesothorium-1 from barium, in the *Journal of the American Chemical Society* for Dec. 1926. The separation depends on the fact that the respective ions have different mobilities, and that during electrolysis the faster ion will gradually concentrate in front of the slower, an accumulation of radioactive material being shown by an increase in the activity per unit weight. By introducing other ions in suitable concentrations to keep the boundary sharp, and incorporating the greater part of the solution in agar gel, much more rapid and convenient separation is effected than by fractional crystallisation. Since mesothorium-1 is isotopic with radium, it is possible to apply exactly the same method to the separation of radium and barium, as it is known that isotopic ions have identical mobilities. The fact that the ions of mesothorium-1 and radium have greater mobilities than the barium ions shows that the increase in ionic mobility with atomic weight is continuous throughout the whole alkaline earth group.

The Value of Tank Testing.—The value of the method of ship model testing in experimental tanks initiated by William Froude at Torquay in 1868 has been proved over and over again. Such testing gives the designer a mass of useful data and settles the form of hull and propeller to give the best results. But as Pepys said long ago, "It seems worthy of note how small things are sometimes found to mar or mend a ship's quality of sailing." The importance of minor details was really the theme of Mr. G. S. Baker's paper, "The Economy of Tank Testing of Ship Forms and Research in Ship Propulsion" read on Jan. 28 to the North-East Coast Institution of Engineers and Shipbuilders. The points dealt with included the form of the shaft webs and brackets; the bossing and direction of rotation of the propellers; the shape and section of the blades. At first, tank testing was confined to the determination of the factors which make up the resistance of war-ships in still water. It was extended to the study of propellers by R. E. Froude and to merchant ships by Messrs. Denny. In the National Tank, of which Mr. Baker is director, during the years 1924–26, no less than 80 designs were tested, and in an appendix to the paper are notes on the results.

Diet and Cancer.

THERE have been and are all sorts of statements about the relation of diet to the occurrence of cancer. We are told that eating raw carrots will prevent and even cure it; others attribute efficacy to onions, others to a salt-free diet; tomatoes, on the other hand, have been suspected of causing cancer. Particularly common is the suggestion, which appears at times to have crystallised into a belief, that vegetarians suffer from malignant disease less than ordinary people who take a fleshy diet.

None of these statements has been subjected to critical inquiry; and indeed such inquiry is by no means easy, for it is hard to find two bodies of persons, in other respects wholly comparable, who differ only in their enjoyment or rejection of meat. The vegetarians in Great Britain, for example, could not, without the strictest inquiry, be regarded as a sample of the population which differed from the normal only in their avoidance of meat; there are many grades and subclasses of vegetarians, but, taken as a whole, they form a group distinguished in many modes of life and thought besides their diet. In the world at large, vegetarianism, in short, is generally a character associated with other exceptional features of body and mind, and any advantage or disadvantage which vegetarians may show in the incidence of disease may be due to their general make-up as likely as to the nominal outward sign of it. The study of such associations in man is, indeed, difficult, and is liable to be extremely fallacious.

Particularly welcome, therefore, is the report on the incidence of cancer in certain religious orders by Dr. S. Monckton Copeman and Dr. Major Greenwood.[1] With the co-operation of the ecclesiastical authorities and with an amount of detailed inquiry which must have been even more troublesome than it seems, they have collected the necessary statistics in a number of religious houses in England and elsewhere. The monks, nuns, and lay brothers in these communities are all essentially vegetarians: but we can be pretty sure that vegetarianism is no more than an incidental circumstance, and that the nature of the diet has had no influence in determining the membership of these communities. Among the Carthusians and Cistercians the rules are especially strict, and a life which is spent in silence in a cell from which the monk comes out only for a nightly service, for a meal in the refectory on Sundays, and for a weekly walk, cannot be said to involve much of that hurry, luxury, and excess to which cancer and other sickness is so often ascribed. But the results of this minute inquiry into their mortality shows that, while perhaps as a whole the mortality is in some instances rather less than would be expected in persons of similar age and sex in the outside world, there is no evidence at all of any immunity to cancer. Thus in a Cistercian house in England, 427 people lived between 1800 and 1920: there were 104 deaths against an expectation of 82 in the general population, and of these 5 certainly, and 3 probably, died of cancer, as compared with 5 or 6 in non-monks. Cistercian nuns in England and a Belgian house of the same order give similar results, as do Benedictine and Carmelite communities in which the rules are not quite so strict. Taken separately or together, the figures lend no support to a proposition that cancer is either less or more common inside monasteries than among the contemporary comparable part of the population outside.

Finally, data are given which were collected less minutely and completely from 57 Cistercian houses in different parts of the world: the figures seem to show a singularly small number of deaths from cancer, but, as the authors point out, the calculations are subject in these instances to so many qualifications that one is once again reduced to the conclusion that there is no evidence of any difference either way. Any one who feels inclined to rush in and solve the problem of the causation of cancer by statistical methods should study carefully this admirable example of how such work should be done: it is much more difficult than some enthusiasts imagine.

Maori Navigation.

THE vessels used by the peoples of the Pacific in their migrations and colonisations are of primary importance in Oceanic ethnology. They have been described by various writers, but only partially, and generally from the technological side. Now, in an interesting *Bulletin of the Dominion Museum of New Zealand*,[1] Mr. Eldon Best has collected all that is known or can be learned from native sources about Maori canoes. Every aspect of the subject is discussed and fully illustrated by copies of early prints or modern photographs.

Some types of Maori canoes have entirely disappeared. The double canoe, formed by two dug-outs united by a platform, survived until about 1830. The occurrence of the single canoe with one outrigger is denied by some writers, although it is said to have been seen by Captain Cook. The single canoe with double outrigger is said to be only mentioned in tradition. This becomes important when it is noted that Indo-Javan vessels twelve centuries ago had double outriggers.

The only native canoe now used is that without an outrigger. The generic name is *waka*. Varieties are distinguished as the *waka taua*, war canoe, *waka tete* used for fishing and travelling, and the *waka tiwai* and other small craft used in calm waters.

The building of the *waka taua* is fully described. The tree, of *totara*, *kauri*, or other timber, was reserved by clearing the bush around or by a taboo. A strip of bark might be peeled off one side to initiate decay and facilitate hollowing out. On an auspicious day, after fasting and ritual, the trunk was felled. Sometimes the lower part was scarfed, or the uncovered roots were burned, or an ingenious machine on the ballista principle was used. The trunk was charmed to prevent damage in falling. The hollowing was performed by burning and by the stone adze. Canoe makers wore only one garment, and their food, reserved for them alone, was cooked apart. It was etiquette for a visitor to throw his spear at the canoe. If it stuck, the omen was favourable. The hull was hauled to the water side by ropes, often for long distances, by many people. Charmed skids eased the canoe over rough ground. Sometimes the hull was composed of more than one piece.

The sides of the dug-out were heightened by an ornamental top strake, butted and lashed to its top edge by strings of flax, and caulked with fibre. The join was covered by a batten. The ends of the top strake were drawn in by a tourniquet and the lashings tightened with a lever. The ends of the dug-out were fitted with figure-head and stern piece, coloured red and black and ornamented with feathers. The deck was a mere grating. The launch was carried out according to ritual and was followed by a ceremonial feast.

[1] New Zealand, Dominion Museum. Bulletin No. 7: The Maori Canoe. By Eldon Best. Published under the direction of the Board of Maori Ethnological Research, for the Dominion Museum. (Wellington, N.Z.: W. A. G. Skinner, 1925.)

Mr. Best describes in less detail the fishing and river canoes, and also the canoes of the Chatham Islands. An account is also given of ceremonial observances in the use of canoes.

The common mode of propulsion was the paddle, but poling was often resorted to when ascending streams or in shallow water. Steering was effected by a long paddle at the stern or by directions to the paddlers. Mr. Best gives specimens of the songs sung while paddling. The sails formerly used were triangular, with the small end downward. They were made of matting or laced leaves. Generally only one sail was used, but large canoes might have two or three. Stones were used as anchors. They were used in the natural state or with grooves pecked round the middle to fit the rope, or in baskets. Baling was performed with carved balers having the handles projecting forward.

Mr. Best gives a summary account of canoes of the Pacific area, quoting from various authors. Gilbert and Loyalty Island canoes are included with the Polynesian, and only short notes are given on those of Melanesia, Micronesia, and Indonesia. At the end of this chapter Maori methods of navigation are described, and the Maori and Moriori compass points enumerated, without reference to other island names.

An interesting chapter is devoted to Maori traditions of the discovery and settlement of New Zealan by visitors from eastern Polynesia, from an islan Hawaiki, which Mr. Best identifies with Tahiti. Th first voyagers were Kupe and Ngahue. They circumnavigated New Zealand and named it Aotea-roa They found no human inhabitants but reported o their return to Hawaiki that the most valuable products of Aotea-roa were the *moa* and *pounam* (nephrite). Toi, a later visitor, found the island inhabited by the Maruiwi or Mouriuri, a dark-skinne people with bushy hair. The voyage of Toi and tha of his grandson Whatonga led to the colonisation o New Zealand, and voyages thereto became frequent Mr. Best gives an account of Maori voyages and th historic canoes in which they were made.

With its list of Maori navigation terms, bibliography, and index, the work forms a valuable compendium and record of one group of Polynesian cano builders and navigators, and Mr. Best has done rea service to Oceanic ethnology by its compilation.

In some places the linguistic comparisons are weak Tonga *hama*, Rotuma *sama*, Fiji *thama* are assume to be derivatives of the Maori *ama* (outrigger). Th Tonga *fohe* and Samoa *foe* are said to come from th Maori word *hoe* (paddle). The Fijian *wanka* (cano and shrine) is said to be a Maori term. But the name as found in Tonga, Rotuma, and Fiji are older than i Maori. The original words were *semang* or *soma* (outrigger), as in the Moluccas and Batjan; *boseh* *borsi*, or *bogsai* (paddle), as in Java, Sumatra, and th Philippines; and *banka* or *wanga* (canoe), as in th Philippines and Celebes.

Sidney H. Ray.

Planets and Periodicities.

THE nineteenth century discarded horoscopy of the weather with the other appurtenances of astrology. Dr. Z. Kamerling[1] would have us reverse the verdict and employ the motions of the planets as the basis of long-range forecasting. His thesis is that widespread periodicities must have a cosmic origin, and sunspots having failed, there remain only the planets. Accordingly he investigates periodicities of the length of the 'synodic rotations,' that is, the intervals between the dates at which the various planets are nearest to the earth. (It appears that the theoretical basis of this planetary connexion has been given in a previous paper; one wonders what it can possibly be.) These give him in years: Venus 1·60, Mars 2·13, Jupiter 1·09, Saturn 1·035, Uranus 1·018. As material he has forty years of average monthly rainfall over east Java and over west Java, twenty years' rainfall at Pernambuco, and temperatures at Winnipeg, Konigsberg, and Zwanenburg. The method is to write down the monthly data in sets corresponding with the 'synodic year,' so that, for example, all the months of perigee come in the same vertical column, and to plot the smoothed means of these columns. From his graphs Dr. Kamerling concludes that there are real periodicities corresponding with the synodic periods of each planet, giving maxima generally near perigee and secondary maxima near apogee.

Such a result would be of considerable importance if substantiated, as explaining the origin of a number of periodicities of a little more than a year which have been suggested from time to time, but unfortunately the author has not done all he might to prove his case. He does not express his periodicities as Fourier series, nor does he attempt to determine their exact length. The original data are given only for the east Java rainfall, and here inspection shows that the annual variation has not been completely eliminated. They show, in fact, a residual mean annual variation with a range of 16 mm., which is of the same order as the ranges of the planetary periods. The normal used apparently covers the first thirty-three years, so that the error is entirely concentrated in the last seven years, and falsifies any apparent periods up to 1·1 year. The supposed period for Uranus (1 year 4 days), with a range of 18 mm., is almost entirely due to this residual annual variation. The author does not give the standard deviations of the data which he uses, so that no test of reality can be made. The Venus period in east Java, which has by far the largest range of any, may be taken as a test case. The amplitude of the corresponding Fourier series is found to be 9 mm., and the standard deviation of the original 480 values is 63 mm. The amplitude is therefore 4·5 times the expectancy on a chance basis, and the period seems to be real. Its exact length, however, turns out to be 1·58 year, while the 'synodic year' of Venus is 1·60 year; this means that the maximum phase shifts by about 120° in forty calendar years, which seems too great, and the interpretation suggested is that there is a periodicity in the east Java rainfall which happens nearly, but not quite, to coincide with the Venus synodic year.

The curve for Mars shows very little trace of the whole period, but a well-marked half-period of 1·06 year, which may be due to the residual annual variation in the data. The present writer is not impressed by the supposed approximation of the maxima to perigee and apogee, since to him the graphs rather suggest a haphazard distribution of phase. Hence it seems necessary for the author to repeat his work, using more refined methods of analysis, and where possible longer series of data. The title of the paper is a misnomer, since the results would be of little use for forecasting purposes.

[1] "Grondslagen voor een Weervoorspelling op langen Termijn." Door Dr. Z. Kamerling. 1: Enkelvoudige Perioden van Wijziging der Weersgesteldheid. Pp. 30. (Leiden: A. W. Sijthoff, n.d.) n.p.

The Indian Lac Research Institute.

THE importance of lac in the markets of the world is well known to many; also the fact that at the present time India enjoys practically a world-wide monopoly of the lac industry. Owing to serious fluctuations in the price and output from time to time, speculation is rife and steps are being taken with the object of endeavouring to stabilise the trade. A Government inquiry was carried out by Messrs. H. A. F. Lindsay and C. M. Harlow, their report being published in 1921. An outcome of the report was the formation in the same year of the Indian Lac Association for Research. It was decided to build and equip a Lac Research Institute and to run in conjunction with it a small experimental plantation. The Association is managed by a committee of Europeans and Indians representing all branches of the trade. Funds are obtainable by a small cess imposed by the Government of India on all exports of lac, manufactured and unmanufactured. A report of the work of the four years (to Mar. 31, 1926) has been issued (Calcutta: Thacker, Spink and Co.).

The greater bulk of the lac produced comes from Central India, *i.e.* the Central Provinces and Chota Nagpur. This factor determined the selection of the site for the research institute. Ninety per cent. of the lac produced comes from a fairly compact area comprising Chota Nagpur, the Feudatory States of Orissa, a few adjoining districts of the Central Provinces, and a few adjacent areas in Bengal and the United Provinces. From this area Bihar and Orissa claim more than half the annual production of lac in India. Thus Ranchi, one of the capitals of this Province, was selected as the home of the future Institute. The local government provided a site of 110 acres a few miles out of the town on favourable terms, and construction work was commenced in 1924, the foundation-stone being laid by the Governor of the Province. The Institute building includes laboratories for biochemistry and entomology and was finished in August 1925. The research staff consists of (1) the director and biochemist appointed in Oct. 1923, (2) three assistants to the biochemist appointed in June 1925, (3) an entomologist and three assistants, all appointed in 1926. The biochemist, who is also director, is Mrs. Dorothy Norris, and she has been in charge since 1923.

Lac production in the past has been either undertaken by the officers of the Indian Forest Department or by local proprietors and others, the material being sold to middlemen for transmission to the big markets. A certain amount of research work has been carried out in recent years by officers of the Department in connexion with improvements in collection and outturn, studying insect pests of the lac, and so forth.

The main objects of the Lac Association may be taken to be the establishment of the lac industry on such a sound commercial basis that competition need not be feared, owing to "(1) A synthetic product such as affected indigo and would have affected rubber but for the drop in price of the natural product. (2) The establishment in other countries of the lac insect itself as has been done in the case of silk."

The Forest Department in the Province is co-operating with the Institute by affording facilities for experimental work in selected areas of forest, thus supplementing the experiments which are being carried out with species, spacing, and so forth on the Institute's own land. The work of the Institute is being welcomed in the Province. As an example of a purely private and commercial undertaking, even though assisted by Government, its inauguration in India is a striking illustration of modern progress.

Women in Factories.

ON Jan. 28, Prof. Edward P. Cathcart lectured at the Royal Institution of Great Britain on "The Physique of Women Employed in Industry." He began his lecture by deploring the fact that while a large amount of work has been done on the anthropometry of man, little attention had been given to the determination of the physical measurements of women. He points out that a real necessity for such knowledge exists quite apart from the theoretical scientific value of the facts, for if, as is likely, legislative action is to be taken with regard to protection from overloading, then definite knowledge will be required.

The problem was studied along the following lines:

(1) The determination of the physical characters of the average woman engaged in industry.

(2) The determination in the laboratory of the optional load.

(3) The determination of loads actually carried in the course of ordinary work by women.

Details of the first section of the research were presented in the lecture. Some 3000 factory women were studied, and as controls a group of unemployed women and a group of women students. Records were obtained of the age, weight, height, lumbar pull, grip, and crush. The factories represented a variety of trades. The heaviest work done was in the chemical and brick trades, and Prof. Cathcart paid a tribute to the physical strength and grace of the women, although they were drawn from one of the worst districts of Glasgow.

A good correlation was found to exist between the various strength tests, indicating that there is, if the strength depends mainly on muscle development, a more or less uniform development of muscle in the different subjects, or, if the strength tests are indicative of more than muscle development, then the factor operative is uniform for all types of muscle activity.

A comparison of the unemployed and the employed showed that the unemployed were of poorer physique than the employed. This did not appear to be due to lack of nutrition or flabbiness of muscle through lack of use. The college women tested exceeded in height, weight, and strength the other two groups, and from the statistical evidence given, this did not appear to be due to bad sampling. Prof. Cathcart thinks the difference is probably due to the fact that the college women had already been selected by medical examination, that they received good physical training, and also that strength is not merely a function of the amount of muscle present but is also related to mental alertness that enables a subject to co-ordinate his powers more successfully when called upon to produce some extra effort. From a practical point of view, he thinks it would be well if women below a certain fitness factor were not employed in hard factory work; also that those employers who encourage physical training are doing work that is valuable both from the point of view of the worker and of the work.

We would also add that if Prof. Cathcart's findings as to a fitness factor can be substantiated, the knowledge will be of very great value to those engaged on vocational guidance. Careful studies such as this are of very great value and are applicable to a wide range of problems.

University and Educational Intelligence.

Cambridge.—The Council of the School of the Biological Sciences has been constituted as follows: Dr. Adrian, Prof. Barcroft, Mr. Bartlett, Mr. Blackman, Prof. Buxton, Mr. Forster Cooper, Prof. Dean, Sir F. G. Hopkins, Mr. Nicholas, Dr. Rideal, Prof. Seward, and Prof. J. T. Wilson.

The Faculty Board of Medicine has reported in favour of continuing the diplomas in public health, hygiene and tropical medicine, and hygiene until 1930, but for no longer unless the University otherwise determines at a later date. The foundation in 1922 of the London School of Hygiene and Tropical Medicine has altered the situation at Cambridge. When the new school is completed it should offer facilities for teaching and research with which Cambridge would be unable to compete. The Cambridge diploma in public health established in 1875 may be succeeded in due course by analogous diplomas at the new school.

The provision of facilities for special study and teaching in neurology and mental hygiene at the Maudsley Hospital, and the fact that only part of the course of study for the diploma in psychological medicine could be well provided at Cambridge, has led the Faculty Board to recommend that this diploma be discontinued as from October next. The Faculty Board recommends that the diploma in medical radiology and electrology should be continued for a further period of three years, with a fresh provision that before admission to the second part of the examination the candidate should have had a proper clinical experience of the subject.

Reading.—Mr. Alfred Palmer, president of the council of the University, has been given the degree of Doctor of Science *honoris causa*. This is the first degree which has been awarded by the University.

From University College, London, we have received "These Hundred Years," the oration delivered by Sir Gregory Foster on the occasion of the thirtieth celebration by the College Union Society of the foundation of the College. The title of the address is a reminder that the College centenary is to be celebrated this year. The great transformation—religious, political, social, and educational—that has taken place in these hundred years is, as Sir Gregory Foster says, due largely to the progress of science. He quotes Sir John Herschel's scathing criticism of the state of the exact sciences at the beginning of the nineteenth century: "Mathematics was at its last gasp, astronomy was nearly so. . . . The chilling torpor of routine had spread itself over all those branches of science which wanted the excitement of experimental research." There was no place in England where chemistry was systematically taught, and there was no chemical laboratory until one was opened at University College in 1828. The important part played by the College in the astounding progress witnessed by the hundred years that followed is briefly touched on in the address and will doubtless be celebrated at length in due course. In accounts of the origin of the College (and of the University of London) its debt to the poet Thomas Campbell is commonly acknowledged, but it is not so commonly recognised that the great principle of freedom from religious rivalry which the poet so eagerly and successfully championed was by him imbibed from the University of Berlin, founded, under the guidance of Wilhelm von Humboldt, in 1809, "unattached to any particular creed or school of thought, and devoted only to the interests of science and learning."

Calendar of Discovery and Invention.

February 20, 1880.—In one of the notebooks of David Edward Hughes preserved at the British Museum is an entry dated Feb. 20, 1880: "Mr. Spottiswoode, President of the Royal Society, Prof. Stokes, and Prof. Huxley visited me to-day at half-past 3 P.M. and remained until 6 P.M. in order to witness my experiments with the extra current Thermopile, etc." Hughes was then making experiments in the transmission of signals across space by means of the radiation given off by what he called the 'extra current' from a small spark coil, using for reception a Bell telephone and battery connected to a separate receiving circuit including sometimes a microphone. Neither Hughes, however, nor his visitors had any conception that the effects obtained were due to electro-magnetic waves.

February 21, 1824.—While professor of chemistry at Jena, Johann Wolfgang Döbereiner in 1823 discovered that when platinum in a fine state of division, known as platinum black, is placed in oxygen, it absorbs many hundred times its own volume with a considerable rise in temperature. Spongy platinum he found acted in the same way, and on Feb. 21, 1824, he patented his lamp, in which a stream of hydrogen is ignited by being directed on to such platinum.

February 22, 1804.—Trevithick, the famous Cornish engineer, was a pioneer in the use of high-pressure steam and was the father of the locomotive. His first practical experiments with a railway locomotive were made at Merthyr Tydvill in 1803–4, and on Feb. 22, 1804, his engine conveyed 10 tons of ore, 70 men, and five wagons a distance of 9¾ miles at about 5 miles an hour.

February 22, 1831.—The virtual founder of the British Association was Sir David Brewster. Johnston the chemist, in 1830, had written an account of the German Association of men of science. On Feb. 22, 1831, Brewster wrote to Prof. Phillips at York: "It is proposed to establish a British Association of men of science similar to that which has existed for eight years in Germany, and which is now patronised by the most powerful sovereigns of that part of Europe. The arrangements for the first meeting are in progress; and it is contemplated that it shall be held in York, as the most central city for the three kingdoms." Murchison, Robison, J. D. Forbes, and Vernon Harcourt were among its chief promoters.

February 24, 1891.—The process for producing seamless steel tubes such as are used in modern boilers is due to Reinhard and Max Mannesmann, one of whose patents is dated Feb. 24, 1891. A heated round billet is spun at a high velocity by rollers which, being slightly inclined to one another, also give the billet an endwise motion. A flow of metal takes place from the interior outwards, a tube being formed the interior of which is smoothed by its being forced over a mandril.

February 24, 1896.—No discovery created more stir in scientific circles than that of the Rontgen rays, but no sooner had it been made known than a new field of investigation was opened up by Henri Becquerel, who, seeking to test whether such rays always accompanied the excitation of phosphorescent light, was led to the discovery of radioactivity. His experiments were made known to the Paris Academy of Sciences in his memoir, "Radiations émises par phosphorescence," read on Feb. 24, 1896.

February 26, 1788.—The Linnean Society was founded through the efforts of Sir James Edward Smith, the inaugural meeting being held on Feb. 26, 1788, at the Marlborough Coffee House. E. C. S.

Societies and Academies.

LONDON.

Royal Society, Feb. 10.—**C. D. Ellis** and **W. A. Wooster**: The photographic action of β-rays. The β-ray spectra of radio-active bodies were recorded as usual on a photographic plate, but homogeneous beams separated by magnetic deflexion were used. The reciprocity law is found to hold, and the form of the blackening curve is independent of the time of development and of the velocity of the particles between $H\rho$ 1450 and $H\rho$ 5830. The blackening curve follows a simple empirical formula which is identical with that holding for the blackening by X-rays, the constants in the formula showing the same variation with velocity as holds for variation in frequency in the case of X-rays.

C. D. Ellis and **W. A. Wooster**: The relative intensities of the groups in the magnetic β-ray spectra of radium B and radium C. With the method used, the intensities of the groups in the two spectra are measured on the same scale and refer to equal numbers of disintegrating atoms. An interesting result is that the ratio of the intensities of the groups due to conversion of the same frequency γ-ray in the K and L levels is independent of the frequency and equal to that occurring in the ordinary external absorption of X-rays. Using Gurney's determination of the number of electrons in the strong groups of radium-B, the number of electrons in all the other groups are deduced. Hence the total number of secondary electrons emitted from these two bodies can be determined.

A. Muller: An X-ray investigation of certain long-chain compounds. The substances were in the form of well-developed single crystals. They contain straight carbon chains of identical or very nearly identical zigzag structure. The angle between two lines connecting the centres of three consecutive carbon atoms is little different from the tetrahedral angle (109° 30′). The chains can be represented by rods of elliptical cross-section. In the crystals these rods are packed in bundles or, in other words, with their axes parallel to a fixed direction in the crystal lattice. The density of packing of these rods is the same for all the substances. Comparisons between X-ray data and others obtained by Langmuir and Adam from measurements of mono-molecular films of long-chain compounds, suggest that the crystal structure and the structure of the compound film are very similar, if not identical.

G. H. Briggs: The straggling of α-particles from radium C. The variation in velocity is measured by the magnetic deflexion method when the rays passed through various thicknesses of mica. The deflected and undeflected bands produced on a photographic plate are analysed by a microphotometer. The distribution of energies on emergence is very approximately Gaussian in form. From the energy distribution, the straggling of the ranges can be calculated at any point in the region investigated; it is about 1·4 times that predicted by Bohr. Half the total straggling in range occurs in the first 2·4 cm. of the path. The discrepancy between theory and experiment would be explained if transfers of energy occur twice as often as theory indicates.

G. H. Briggs: The decrease in velocity of α-particles from radium C. For velocities less than 0·55 V_0, the velocity decreased much more rapidly than was found by Marsden and Taylor, but is in agreement with the results near the end of the range found by indirect methods by Kapitza and by Curie. The ratio of the number of singly to doubly charged α-particles varied as $V^{-4\cdot3}$. Experiments to detect any lack of homogeneity in the initial velocities of the α-particles gave no evidence of velocities greater than the average by more than 1 in 3000. Velocities less than the maximum were present, due probably to absorption in the source.

L. H. Thomas: On the capture of electrons by swiftly moving electrified particles. The chance that a fast α-particle will capture an electron is calculated in two cases; for particles with velocity greater than 8×10^8 cm./sec. moving through hydrogen or helium, and for particles with velocity between 4×10^8 and 2×10^9 cm./sec. moving through heavy matter. The method is to split up the process into a close collision of the particle with an electron and a close collision of this electron with an atomic nucleus. The results are in agreement with those obtained experimentally.

Linnean Society, Jan. 20.—**H. Graham Cannon** and **Miss S. M. Manton**: Notes on the segmental excretory organs of Crustacea. The patterns of the maxillary gland efferent ducts of the Branchiopoda show a marked uniformity. The simplest type is that of Estheria. In Chirocephalus there is a divergence from this pattern, probably correlated with the absence of a shell-fold. In the maxillary gland of Anaspides the pattern of the duct is the same as that of Chirocephalus. The maxillary gland of each possesses a muscular sphincter controlling the exit of the efferent duct from the end sac. The entire gland is mesodermal. The Lophogastridæ represent primitive Peracarida, from which both the modern mysids and isopods could have evolved. The segmental excretory organs of the former are antennal glands and of the latter maxillary glands. Lophogaster possesses both antennal and maxillary glands.—**R. R. Gates**: The tundra vegetation of Russian Lapland. The plant-breeding station at Khibiny, in Russian Lapland, north of the Arctic Circle, in lat. 67° 44′ N., is on Lake Ymandra, and is partly surrounded by mountains which reach a height of nearly 4000 feet. The summer season begins about the middle of June, when the ice goes out of the lake, and ends about the end of August. During this short season most of the plants bloom twice, June and August. The snowfall is not heavy and the rainfall about 450 mm. In February the lowest temperature is about −36°·4 F., while in June—the warmest month—the mid-temperature is 53°·6 F. and the maximum 86° F. There is very little rain from May to August, but the winds are always very strong and have a marked effect on the vegetation. There are many kinds of tundra. The mountain rock tundra above the tree-line at Khibiny is very similar to the low rock tundra on the Arctic coast. Moor tundra is typical of Siberia, and but little of it is found in the Kola Peninsula. Cladonias and other lichens make up a conspicuous element and give a whitish character to the landscape. This may be free from trees (*chuna* tundra) or may be interspersed with pine. In the Ural Mountains is *Flecken* tundra, characterised by its patchy covering of vegetation with areas of bare yellow clay. In *Klotschkovataya*, or tufted tundra, in the Kola Peninsula, the surface of the ground is broken into polygonal areas, which may be thirty feet across and are covered with vegetation. Between these *Klotschy* are crevices which may be ten feet deep and six feet wide, with vegetation at the base. All these forms of tundra have many features in common, Cladonias and other lichens as well as heaths and woody creepers being conspicuous elements in the plant-covering. Tundra vegetation appears to be chiefly the result of a soil which is wet and frozen during much of the year, general low temperature, and continuous high winds. The continuous daylight during the greater part of the summer season favours quick maturity in the flowering plants. Occasional summer fogs occur, but farther north on the Murmansk coast they are much more frequent and very dense.

Geological Society, Feb. 2.—**V. C. Illing**: The geology of the Naparima region of Trinidad (British West Indies). The area around San Fernando is covered almost entirely by a series of sands, clays, and marls of Lower and Middle Tertiary age, the marls being responsible for the black soils which have become the home of the sugar-cane industry. These Tertiary deposits have been formed in two separate basins, separated by an important zone of uplift extending from San Fernando in an east-north-easterly direction. The Upper Argiline, generally considered to be Cretaceous, is placed in the Upper Eocene on the evidence of the foraminifera, and is followed unconformably by a series of sands and silts, also of Upper Eocene age. The Oligocene is only partly represented, but the late Oligocene and early Miocene Periods show a thick series of clays, marls, and sands. The marl facies is almost completely restricted to the southern basin, and is merely a facies of the more widespread foraminiferal clays. The rocks of the area are moulded by a series of thrusting movements coming generally from the northward, the main trend of the folding being east-north-easterly. Associated with the movements which have clearly recurred at distinct periods in Tertiary times, there has been emergence of the central land-ridge and the formation of shallow-water beach-deposits at the maximum periods if uplift.—**W. L. F. Nuttall**: Tertiary Foraminifera from the Naparima district of Trinidad (British West Indies). The rocks of the Naparima district consist of an upper and a lower series, which rest upon one another unconformably. Foraminifera are abundant in these beds, and indicate that the upper series is of Miocene-Oligocene age and the lower series Upper Eocene. There are two distinct areas separated by a zone of over-thrust faulting. The stratigraphical sequence and foraminiferal faunas of these areas are dissimilar, and the explanation offered is that they were originally two separated basins of deposition.

Edinburgh.

Royal Society, Jan. 24.—**Henry Briggs**: Rock-faulting from the engineering standpoint. The bearing of Mohr's theory of rupture on the angle of fracture of rocks of different degrees of brittleness is discussed, and the character of the three-dimensional stress-systems required to produce normal, transcurrent, and reversed faulting is ascertained. This carries the quantitative methods of the engineer into a branch of geology.—**W. J. M'Callion**: The geology of Gigha. Gigha is a small island off the western coast of Kintyre and about 5½ miles south-east of West Loch Tarbert. It is 6 miles in length from north-east to south-west, and has a greatest breadth of 2 miles. The rocks of the island are composed of quartzites, phyllites, and epidiorites belonging to the Erins Quartzite division of the Ardrishaig group which is so well developed in South Knapdale. Kainozoic crinanites and olivine dolerites are very abundant.—**A. R. Normand, J. B. M. Ross**, and **E. Henderson**: The distribution of intensity in the X-ray spectra of the normal saturated dicarboxylic acids, their diethyl and mono-ethyl esters. The intensity distribution among the several orders of reflection from the principal spacing planes was calculated by Shearer's method. The calculated and observed results on comparison showed good agreement, thus confirming the structures assigned by the authors to this series of compounds.

Paris.

Academy of Sciences, Jan. 10.—The president announced the death of Antoine Balland, corresponding member for the Section of Rural Economy, and of Haton de la Goupillière, free member.—**Emile Borel**: Systems of linear forms with a left symmetrical determinant and the general theory of play.—**Emile Borel**: A problem of geometrical probabilities relating to the circle.—**G. Ferrié** and **R. Jouaust**: A free pendulum maintained by a photo-electric current and its application to the problem of time. The free pendulum, the mechanism of which has been described in an earlier paper, has been observed for more than twelve consecutive hours, and the interval of time between two successive records of beats has been constant to 0·001 sec., an order of accuracy higher than that hitherto attainable.—**L. Gustave Du Pasquier**: Groups of Hamiltonian quaternions.—**Mme. M. Piazzolla-Beloch**: Hyperelliptic surfaces of rank 2.—**Tibor Radó**: The area of curved surfaces.—**Norbert Wiener**: A generalisation of functions with limited variation.—**André Weil**: Functional spaces.—**Stefan Kempisty**: Integration of the regular differential.—**Arnaldo Masotti**: The composition of the movements of a perfect liquid parallel to a fixed plane.—**R. Mazet**: Flow through a circular orifice.—**F. da Costa Lobo**: Two interesting prominences. A description of observations made with the spectroheliograph at the astronomical observatory of the University of Coimbra on Aug. 5 and Oct. 7.—**Th. Vautier**: Velocity of waves [of explosions].—**Paul Gabriel Girault**: A mechanical image of hysteresis and the inconstancy of the Steinmetz exponent.—**Louis de Broglie**: The possibility of bringing into agreement the electromagnetic theory with the new undulatory mechanics.—**Léon Brillouin**: Is it possible to detect directly the magnetic moment of the electron? An experiment is conceived which might decide this question. The necessary conditions are difficult to realise, but do not appear to be impossible.—**Albert Pérard**: Quartz standards, checks of the metric unit. Results of the length measurements and of the indices.—**S. Piña de Rubies**: The arc spectrum of europium. Measurements made at the normal pressure between 3100 Å.U. and 2200 Å.U. A list of the wave-lengths and intensities of the lines is given, also a list of lines given by Exner-Haschek and by Eder, attributed to europium but considered by the author to be due to impurities.—**C. Mihul**: New researches on the structure of the spectrum of oxygen.—**Andrieux**: A method of high-temperature electrolysis of oxygen compounds. Application to the preparation of a certain number of metals and of borides. The electrolytic bath consists of a mixture of metallic oxide, boric acid or borax, and fluoride of an alkali or alkaline earth. Electrolysis with a high current density gives the metal (fused or crystalline); with low current density, borides are obtained.—**W. Swietoslawski** and **S. Poznanski**: The equilibrium constant of the esterification reaction in the gas phase.—**Edmond Vellinger**: The rotatory power of organic substances as a function of the pH; malic acid. The curve of rotation of malic acid as a function of the pH generally resembles that given by tartaric acid and can be calculated by the same formula.—**Jean Thibaud**: The polymorphism of the fatty acids.—**Picon**: The action of high temperatures on some metallic sulphides. Iron sulphide heated in a carbon tube *in vacuo* commences to dissociate into its elements at 1100° C., while manganese sulphide volatilises without decomposition at 1375° C. Chromium sulphide decomposes at about 1350° C.—**Charles Dufraisse** and **Henri Moureu**: A method of preparation of the α-diketones, starting with ketones of the type $R.CO.CH=CH.R'$.—**Mme. Ramart-Lucas** and **F.**

Salmon-Legagneur: The action of phenylmagnesium bromide on the trisubstituted acetonitriles. This reaction yields trisubstituted acetophenones. With the exception of trimethylacetophenone, all the ketones described are new.—**Edgar Aubert de La Rue**: Some minerals from the Ivory Coast.—**Léon Bertrand**: The rôle of the Alpine Triassic spur of central Vésubie in the recent landslides of Rocquebillière, Belvédère and Lantosque.—**W. Kopaczewski** and **A. de Moraes Sarmento**: The extreme lability of certain mineral waters.—**O. Munerati**: Three generations of *Beta vulgaris* in the space of one year.—**Abelous** and **Argaud**: The different vicariant modalities in animals without the spleen. A discussion of the modes in which glands may be modified to perform some of the functions of the spleen when the latter has been experimentally removed.—**J. Nageotte**: Coagulation *in vitro* of collagen dissolved in a dilute acid.—**A. Policard**: The phenomena of reparation of fractures studied by the method of tissue culture.—**C. Hosselet**: The genesis of the myofibrils and the radiate structure in the myoblasts of the legs of *Culex annulatus*.—**René Lambert** and **Georges Teissier**: The theory of biological similitude.—**L. Mercier** and **Raymond Poisson**: Remarks on a case of macrophthalmia in an eel.—**A. Astruc** and **M. Mousseron**: The various soluble ferments contained in black mustard (*Brassica nigra*). Mustard seed is rich in ferments. Besides the well-known myrosine, there are also present invertine, amylase, maltase emulsin, and an anaeroxydase.

SYDNEY.

Royal Society of New South Wales, Dec. 1.—**W. G. Woolnough**: The geology of the Flinders Ranges, South Australia, in the neighbourhood of Wooltana Station. The eastern escarpment of the Flinders Range, at Wooltana Station, some 400 miles north of Adelaide, is bounded by a very heavy fault throwing to the east. In the escarpment are exposed rocks of the Adelaide Series (Proterozoic), much better developed than in the type area near Adelaide; Sturtian Glacial Beds attain a thickness of about 1000 feet. They rest upon shallow water or terrestrial sediments, except in one place, where a well-preserved volcanic cone of Proterozoic age is seen. Tapley's Hill Slates (Varves) and Brighton Slates and Limestones follow the glacial series. The topmost beds in the series are red beds, with ripple-marks and sun-cracks, which may have been deposited under desert conditions.—**Edgar H. Booth**: (1) The microphone as a detector of small vibrations. Various military type microphones were examined as to their response to impressed impulses and simple harmonic motions, the detectors being employed with an Einthoven galvanometer. The relationship between thread movement and amplitude of impressed wave is linear for minute amplitudes, and the forms of reproduced and impressed waves practically identical, in the case of certain microphones. (2) Surface waves due to small artificial disturbances of the ground. Waves were produced by dropping a pile driver of mass 0·5 lb. through distances up to 30 cm., the nature and relative amplitude of the waves produced being examined at varying distances from the centre of disturbance by microphones and an Einthoven galvanometer. A value of damping effect for Rayleigh waves for a particular case is given.—**Sir George Knibbs**: Notes on the occurrence of triplets in multiple births. In a previous solution of the probabilities of triplets being produced from one ovum or from two or three ova, it was assumed that triplets were never produced from a single egg. It seems certain, however, that they are sometimes so produced. A probability-analysis, similar to that possible in the case of twins, is not possible in the case of triplets; the numbers produced from one egg must be a matter of observation. Tables are given, however, which show for various numbers of cases of triplets produced from one egg, what the numbers will be of those produced from two or three eggs out of the total of 1489 cases analysed, in which the numbers of males and females were distributed as follows, namely, three males, 343 cases; two males and one female, 390 cases; one male and two females, 395 cases; and three females, 361 cases. It is remarkable that the females are in excess instead of the males. The following illustrates the probable distribution in a total of 1489 cases:

Cases from—						
One egg	0	1	2	20	200	400
Two eggs	1327	1324	1321	1267	727	127
Three eggs	162	164	166	202	562	962

—**A. R. Penfold**: The essential oils of *Eriostemon Coxii* Mueller and *Phebalium dentalum* Smith. The first-named plant has been recorded from one locality only, Sugar Loaf Mountain, near Braidwood, New South Wales. The second is very plentiful in the Port Jackson district of New South Wales. The oils from both were of a pale yellow colour, and possessed a pleasant fruity odour closely resembling that of the passion fruit (*Passiflora edulis*). Their chemical and physical characters were determined.—**M. B. Welch**: An examination of defective New Zealand kauri (*Agathis australis*). New Zealand kauri milled from buried logs obtained from swamps is liable to become worthless due to seasoning defects, the tensile strength being practically equal to the compressive strength. The weakness is evidently caused by a reduction of the strength of the tracheid walls, with the result that they become spirally cracked by the elongation of the bordered pit openings, due to internal seasoning stresses. There is apparently no variation in the rate of absorption or loss of moisture and the ash content is normal.—**F. A. Coombs**, **W. McGlynn**, and **M. B. Welch**: Notes on wattle barks (Part 2). Analyses of barks stored for thirty years indicate that no loss of tannin has occurred, and there is no alteration in the solubility of the tannins. The loss found when solutions of wattle tannins, in contact with partially spent bark, are exposed to high temperatures, is probably due to an insoluble starch tannin combination. This starch tannin compound is soluble at temperatures approaching boiling-point, but separates out on cooling. The high temperatures necessary to overcome adsorption are responsible for the alteration in colour of the tannins.—**W. R. Browne** and **H. P. White**: On the hypersthene-andesite of Blair Duguid, near Allandale, N.S.W. This outcrop of andesite is about 1¼ square miles in area and was formerly regarded as the stump of a volcano contemporaneous with the Lower Marine series of the Permo Carboniferous system. Reasons are given for considering it rather an inlier of Carboniferous lava. The rock has suffered considerable deuteric alteration in places involving albitisation, change of hypersthene into iddingsite, carbonation, etc. Comparison of chemical analyses of the fresh and altered rock indicates the addition of potash as well as soda during alteration.

Diary of Societies.

SATURDAY, FEBRUARY 19.

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS (Newcastle-upon-Tyne), at 2.30.—L. F. H. Booth: Screening and Washing Plant at Deaf Hill Colliery.—W. Rawling: The Economic Working of Thick Seams in New South Wales.—Paper open for further discussion:—The Chemical Relations of the Principal Varieties of Coal. Prof. G. Hickling.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—W. de la Mare: The Supernatural in Fiction.

Physiological Society (at St. Thomas's Hospital Medical School), at 4. —Demonstrations:—Fœtal Respiration in the Goat, by A. St G. Huggett; The Secretion of Bile and Pancreatic Juice following the Injection of Bile into the Small Intestine, by Prof. J. Mellanby.—E. P. Poulton: Tone in Plain Muscle.—J. Needham: Absorption, Combustion and Constitution in the Developing Avian Embryo.—E. M. Boock, J. H. Burn, and J. W. Trevan: The Accuracy of the Assay of Strophanthus and Squill by different Methods.—Prof. J. Mellanby: The Secretion of Bile.

Birmingham Metallurgical Society (at Girls' High School, Dudley), at 7.—R. P. Bethell: Blast Furnace Practice.

Oxford University Junior Scientific Club, at 8.15.—Exhibition Meeting.

MONDAY, February 21.

Victoria Institute (at Central Buildings, Westminster), at 4.30.—Squadron-Leader P. J. Wiseman: Babylon in the Days of Hammurapi and Nebuchadnezzar.

Royal College of Surgeons of England, at 5.—Prof. B. W. Williams: The Importance of Toxæmia due to Anaerobic Organisms in Intestinal Obstruction and Peritonitis.

Institution of Electrical Engineers (Informal Meeting), at 7.—R. O. Kapp and others: Discussion on National Busbars of Central Europe.

Institution of Electrical Engineers (Mersey and North Wales (Liverpool) Centre) (at Liverpool University), at 7.—J. H. Reyner: Recent Developments in Radio Reception.

Institution of Mechanical Engineers (Graduates' Section, London), at 7.—F. C. Johansen: The Screw Propeller.

Institution of Automobile Engineers (Glasgow Centre) (at Royal Technical College, Glasgow), at 7.30.—E. W. Seaman: The Straight-Eight Engine.

Aristotelian Society (at University of London Club), at 8.—Prof. A. Wolf: Some Aspects of the Philosophy of Spinoza.

Royal Society of Arts, at 8.—Prof. E. G. Coker: Photo-elastic Measurements of Stress Distribution (Cantor Lectures) (2).

Royal Geographical Society (at Æolian Hall), at 8.30.—Flight-Lieut. G. N. Humphreys: New Routes on Ruwenzori.

Medical Society of London, at 9.—D. Armour: The Surgery of the Spinal Cord and Membranes (Lettsomian Lectures) (1).

Royal Society of Medicine (Social Evening).—P. Flemming: Topographical and Medical Notes on Harley Street.

Chemical Industry Club.

TUESDAY, February 22.

Royal Dublin Society (at Ball's Bridge, Dublin), at 4.15.—E. J. Sheehy: The Correlation of Nutritive Value with the Dry Matter Content of Pastures.—Prof. J. Wilson: The Maintenance Requirements of Cattle on Different Kinds of Rations and at Different Rates of Production.

Royal Institution of Great Britain, at 5.15.—Prof. J. S. Huxley: Problems of Animal Growth and Development (4).

Newcomen Society for the Study of the History of Engineering and Technology (at Institution of Mechanical Engineers), at 5.30.—F. Achard and L. Seguin: The Early British Railways as seen by Marc Seguin in 1825: The Four-cylinder Locomotive 'Chittaprat.'—F. Achard: The First British Locomotives of the St. Etienne-Lyon Railway.

Zoological Society of London, at 5.30.—Lord Rothschild: Exhibition of a Mounted Example of the "Dragon" (*Varanus komodensis*), from Komodo Island, Dutch East Indies.—Major C. M. Ingoldby: Exhibition of Specimens illustrating Climatic Phases of some African Squirrels (Genus Heliosciurus).—R. I. Pocock: Exhibition of the Skin of a new Species of Cheetah.—M. Smith: Contributions to the Herpetology of the Indo-Australian Region.—Dr. J. Waterston: A Remarkable Scelionid (Hymenoptera-Proctotrypoidea) from South Africa.—Prof. A. Meek: *Bipinnaria asterigera* (Echinodermata) from the Northumberland Plankton.—R. I. Pocock: The External Characters of the South African Striped Weasel (*Pœcilogale albinucha*).—Prof. W. B. Benham: External Sexual Differences in the Terebellid Worms.—A Collection of Papers by the following Authors, dealing with the Results of the Cambridge Expedition to the Suez Canal, 1924:—P. Fauvel, W. A. Thorpe, O. Carlgren, Dr W. T. Calman, R. Gurney, V. C. Robinson.

Illuminating Engineering Society (at Royal Society of Arts), at 6.30.—H. N. Green: Artificial Light as an Aid to Aerial Navigation.

Institution of Electrical Engineers (North Midland Centre) (at Hotel Metropole, Leeds), at 7.—Col. E. Mercier: Notes on the 60,000-Volt Underground Network of the Union d'Electricité.

Royal Photographic Society of Great Britain (Scientific and Technical Group), at 7.—F. F. Renwick: Turbidimetry and Grain Size.—W. B. Ferguson: The Ferguson Density Comparator.

Institution of Electrical Engineers (North-Western Centre) (at College of Technology, Manchester), at 7.30.—Prof. W. M. Thornton: What is Electricity? (Faraday Lecture).

Institution of Engineers and Shipbuilders in Scotland (at 39 Elmbank Crescent, Glasgow), at 7.30.—H. Brier: The Application of Pre-cooling by Primary Evaporation and Multiple Effect Compression to CO_2 Refrigerating Machines.

Royal Anthropological Institute, at 8.30.—Prof. J. G. de Montmorency: The Custodian of Tradition.

WEDNESDAY, February 23.

Royal College of Surgeons of England, at 5.—Prof. J. H. Evans: Testicular Tumours of Congenital Origin.

Geological Society of London, at 5.30.—Dr. W. D. Lang and Dr. Stanley Smith: A Critical Revision of the Rugose Corals described by W. Lonsdale in Murchison's "Silurian System."—L. G. Anniss: The Geology of the Saltern Area (Torbay).

Association of Special Libraries and Information Bureaux (at 9 Conduit Street, W.), at 6.30.—G. F. Barwick: Directory of Sources of Specialised Information.

Institute of Chemistry (Belfast Section), at 7.30.—Prof. Gregg Wilson: Primitive Australia.

Royal Society of Arts, at 8.—F. H. Carr: Insulin and its Manufacture.

Electroplaters' and Depositors' Technical Society (at Northampton Polytechnic Institute), at 8.15.—T. Johnson: Electro deposition of Iron.

British Psychological Society (Medical Section) (at Royal Society of Medicine), at 8.30.—Dr. Sylvia M. Payne: Observations on the Formation and Function of the Super-Ego in Normal and Abnormal Mental States.

Society of Chemical Industry (South Wales Section) (at Swansea).

THURSDAY, February 24.

Royal Institution of Great Britain, at 5.15.—Prof. J. Garstang: The Progress of Hittite Studies (1).

Institution of Mining and Metallurgy (at Geological Society), at 5.30.

South London Entomological and Natural History Society, at 7.—Lantern Evening.

Oil and Colour Chemists' Association (at 8 St. Martin's Place, W.C.2).—A. A. Drummond: Further Notes on the Behaviour of Phenolic Resins.

FRIDAY, February 25.

Association of Economic Biologists (at Imperial College of Science), at 2.30.—F. Tattersfield and C. T. Gimingham: Laboratory and Field Experiments on Contact Insecticides.

Physical Society (at Imperial College of Science), at 5.—Sir Ernest Rutherford: Atomic Nuclei and their Transformations (Guthrie Lecture).

Royal College of Surgeons of England, at 5.—Prof. J. E. H. Roberts: The Diagnosis and Treatment of Intrathoracic Tumours.

North-East Coast Institution of Engineers and Shipbuilders (at Literary and Philosophical Society, Newcastle-upon-Tyne), at 6.—R. I. Dodsworth: Loading and Unloading Facilities on Board Ship and Land.

Institution of Mechanical Engineers (Informal Meeting), at 7.—Major W. Gregson and others: Discussion on Waste Heat Recovery.

Institution of Engineering Inspection (at Royal Society of Arts), at 7.30.—C. J. Wharton: The Economic Production of Steam by Electricity.

Junior Institution of Engineers, at 7.30.—Dr. C. M. Walter: A Trip in the Norwegian Fjords (Lecture).

Royal Society of Medicine (Epidemiology and State Medicine Section), at 8.—Dr. N. H. Mummery: The Organisation of an Industrial Clinic.

Institute of Brewing (at Institution of Electrical Engineers), at 8.15.—Prof. H. E. Armstrong: Horace Brown Memorial Lecture.

Royal Institution of Great Britain, at 9.—Prof. D'Arcy W. Thompson: The Solids of Plato and Archimedes.

Manchester Literary and Philosophical Society (Chemical Section).

SATURDAY, February 26.

Merseyside Aquarium Society (at Liverpool University), at 3.—Prof. J. Johnstone: Address.

North of England Institute of Mining and Mechanical Engineers (at Neville Hall, Newcastle-upon-Tyne), at 3.—W. Leebetter: Winning Thin Seams of Great Britain.

Royal Institution of Great Britain, at 3.—Dr. J. B. McEwen: Beethoven (1).

PUBLIC LECTURES.

SATURDAY, February 19.

Horniman Museum (Forest Hill), at 3.30.—Dr. W. T. Calman: The Shipworm, a Pest of the Seas.

SUNDAY, February 20.

Guildhouse (Eccleston Square), at 3.30.—C. Bailey: The Religious Experiences of Ancient Rome.

MONDAY, February 21.

London School of Economics and Political Science, at 5.—Prof. A. Wolf: The General Philosophy of Spinoza.

King's College for Women (Household and Social Science Department), at 5.15.—Dr. E. Barker: Population and its Bearing on National Life and Character.

Royal College of Science (South Kensington), at 5.30.—Dr. W. T. Gordon: The Origin and Structure of Rocks (Swiney Lectures). (Succeeding Lectures on February 25, 28, March 4, 7, 11, 14, 18, 21, 25, 28, and April 1.)

University College, at 5.30.—J. Haantjes: Afrikaans Language and Literature. (Succeeding Lecture on February 28.)

TUESDAY, February 22.

University College, at 5.30.—W. J. Perry: Cultural Anthropology. (Succeeding Lectures on March 1, 8, and 15.)

THURSDAY, February 24.

King's College, at 5.30.—Prof. J. D. Wilson: The Mind: Education.

FRIDAY, February 25.

King's College, at 5.30.—Prof. G. H. Wooldridge and others: Discussion on The Problem of the Humane Slaughtering of Animals.

SATURDAY, February 26.

Horniman Museum (Forest Hill), at 3.30.—C. Daryll Forde: Ancient Ships and their Modern Descendants.

SUNDAY, February 27.

Guildhouse (Eccleston Square), at 3.30.—Prof. J. A. Thomson: The Naturalist's Approach to Religion.

SATURDAY, FEBRUARY 26, 1927.

Industrial and Commercial Efficiency.[1]

MR. RAMSAY MACDONALD, during the brief existence of the first Labour Government, must have established a record in the number of special committees of inquiry which he appointed. Not the least important was the Committee appointed to inquire into the conditions and prospects of British industry and commerce and to make recommendations in regard thereto, the general scope of the inquiry to include a survey of overseas markets, a survey of industrial relations, and an assessment of British productive capacity and its efficiency. The report of the Committee is being presented in parts; the first part, dealing with overseas markets, was published in June 1925; in February 1926 a volume appeared dealing with industrial relations; and now, after an interval of a year, a third volume has emerged as a first of two contributions to the subject of productive capacity and efficiency.

When this Committee was about to be appointed, it may be remembered that doubts were expressed regarding the capacity of a Committee composed solely of representatives of finance, industry, and trade to deal adequately with the proposed terms of reference. Major Church, speaking in the House of Commons to the resolution which led to the inquiry, urged the inclusion of representative scientific workers on the Committee, pointing out that they would be in a better position to estimate the possibilities of future trade developments and to appreciate the effects likely to be produced on our commerce by the applications of science to agriculture—the foremost industry of the Empire—and those industries the future of which is indissolubly bound up with the progress of scientific research, than representatives of the classes of the community specifically mentioned. But Mr. Sidney Webb, on whose advice the Committee was appointed, held to the theory that those who would be chosen to represent science on such a committee would necessarily be creative workers whose time would be better occupied in discovery: consequently, scientific workers were neither represented on the Committee nor have they been given the opportunity of expressing their views on the present relations between industry and science. The Department of Scientific and Industrial Research has dealt with that aspect of the inquiry.

This third volume is disappointing. It consists mainly of reports and memoranda prepared by various government departments or officials. There are a brief half-page summary of the work of the National Institute of Industrial Psychology based on the evidence of the Director, and a chapter on industrial art prepared by the British Institute of Industrial Art. Without further inquiry or reference to other bodies, the Committee has prepared a long introductory, inconclusive summary of the subjects dealt with and views expressed in the remainder of the volume. No recommendations are made, only rarely a hint of a suggestion creeps in for the improvement of industrial efficiency in Great Britain, a complacent air of Micawberish optimism pervades most of the pages, but above all, a veil is drawn over the operations of the banks and financial houses of the country—for the present at any rate. The report gives the impression that all will be well when Great Britain has recovered from the destruction of the new things it created in addition to its normal needs during the War, rather than when it has decided to apply the newest advances in scientific knowledge to industry, under the comparatively unfettered direction of those who understand the creative ideas and forces with which they are dealing.

---

[1] Committee of Industry and Trade. Factors in Industrial and Commercial Efficiency: being Part I. of a Survey of Industries. With an Introduction by the Committee. Pp. v+544. (H.M. Stationery Office, 1927.) 5s. net.

Whether the Committee is dealing with industrial structure, the training and recruitment of manual workers and higher technical and professional staffs, standardisation of units of measurement and materials, the function of scientific research, the encouragement of industrial arts, State measures for encouraging home industries and overseas trade, the effect of national and local taxation on certain industries, with all of which this volume deals, it remains entirely non-committal, and the report could be used equally well as a brief either for those who wished to take no action or for those who wished to attempt to improve British industry and trade.

Nevertheless, the memoranda submitted by State departments and other bodies and embodied in this report are of the greatest interest: those on "Industrial Structure" furnished by the Board of Trade, on "Technical Education" by the Board of Education and the Scottish Education Department, and "Industrial Art" by the British Institute, being particularly noteworthy contributions. The chapter dealing with industrial structure gives an account of the marked trend during the last quarter of the nineteenth century towards the limitation of competition in each of the highly industrialised countries and its later development. The information given is already in the possessio of certain sections of the community, but it is th first time, we believe, that it has been summarise in an official publication.

One of the most disquieting features in moder industry is the loss of skill which accompanies th growth of large-scale machine production. Th old traditional crafts, in which the individua carried an article through all stages of its manu facture, are now fast being displaced by mas production, where the individual is responsible fo one of the various processes of manufacture. Th problem of creating and maintaining skill in craft manship is one of the crucial problems of moder industry. For this the Committee supports th view of the Board of Education that we must loo to the schools rather than to the workshop. Th subject of technical training is dealt with at som length. In view of the clamour among certai classes of employers for early vocational trainin the Committee is to be congratulated on expressin its conviction that education is a preparation fo life, and its wider aims and functions should no be sacrificed or subordinated to the demands industry and commerce.

A somewhat gloomy picture is given of the depend ency of Great Britain on the Continental designer for art applied to industry. Too many firms rel entirely upon Paris for their designs and thus ten to limit more and more the creative potentialitie of their own designers. Yet, as it is stated, th artist does not flourish in the ugliness of a norther manufacturing city. "Frenchmen working i Manchester are said to lose their native gifts afte three or four years." The British artist evidentl suffers, like the scientific worker, from lack of a environment congenial to his task, and the narrow ness of outlook of industrial leaders. He suffer from the further disadvantage that the develop ments of the great machine industry had at th outset "the most disturbing and often disastrou effects on industrial art by breaking up the ol craft traditions, revolutionising technique, an weakening or severing the close relations whic previously existed between designer and executant.' Emphasis is laid upon the growing complexity o modern commerce and the obvious need for system atic training in economics and finance. "The fac that the demand for higher commercial teaching o University rank has emanated from economists an educational observers rather than from the repre sentatives of commerce, does not substantiall weaken the case for such education, for almos exactly the same observation could have been mad a generation ago with regard to forms of technical and scientific instruction which have now become firmly established."

In dealing with the subject of scientific research the Committee has relied upon the memorandum furnished by the Department of Scientific and Industrial Research. Other government departments which might have made equally useful contributions to the subject have not been given the opportunity of presenting their views, and apparently the views of leading manufacturers have not been independently ascertained. The Committee states what scientific workers have long known to be the case, that there is still a very imperfect recognition by the industries of the need for the continuous and systematic application of scientific methods both to the invention and improvement of particular methods and processes of production, and to the enlargement of the boundaries of knowledge with regard to the fundamental underlying principles. Most of the scientific workers engaged in industry are absorbed in "tactical research," that is to say, the improvement and development of existing processes, and very few in "strategical research," *i.e.* the search for new products or processes or to the investigation of fundamental laws. The cost of strategical research is usually beyond the means of individual firms, and only the great combinations can afford to embark on such enterprise. The Committee is forced to the conclusion that "freedom and flexibility are essential conditions of fruitful research" and urges the need for the demarcation of functions in the matter of research between the State, which could and should encourage this freedom, and private enterprise, which will usually have a tendency towards secrecy.

It is unfortunate that the Government which appointed this committee did not adopt the suggestion made to bring the representatives of science in intimate contact with the leaders of industry and finance. Had this been done, the chapter on research might have concluded with definite recommendations instead of vague generalities and aspirations. But the fault lies with scientific workers. They fail to realise the urgent need of putting themselves in a position to demand representation on all such bodies. Though faced with every form of combination among financiers, employers, and manual workers, they neglect to combine themselves for the furtherance of their legitimate interests; and while they remain unorganised they can scarcely expect to be considered as a driving or united force in public affairs which affect them as well as the nation.

Evolutionary Philosophy.

Holism and Evolution. By General the Right Hon. J. C. Smuts. Pp. ix + 361. (London: Macmillan and Co. Ltd., 1926.) 18*s.* net.

THE advance, and indeed the proper comprehension, of evolutionary philosophy is to-day suffering greatly from the increase of specialism. This specialism is to a great extent inevitable, but it is at least in part due to an unfortunate by-product of the spreading appreciation of the value of research. The educationist realises that there is no finer training than that which is gained by the conduct of a piece of original investigation. The community as a whole, too, is beginning to appreciate, even though dimly, the extent to which scientific research enters into the foundations upon which rest the health and comfort and prosperity of the modern civilised state.

While this growing appreciation brings with it advantage to the cause of science and to the welfare of mankind, it is not without its disadvantages. Young men without conspicuous natural qualifications are turned on to do a bit of research for their own personal advantage. This is all to the good: they are bound to benefit greatly by being put through the necessary discipline. The harm comes when such prentice efforts are published without due consideration. The work may be simply of inferior quality, or if sound it may be that poor kind of research which consists merely in the transference of certain facts in Nature, of no apparent significance, to the pages of a printed book or journal. Above all, there is the natural tendency, and not merely for beginners, towards intensive research in some very restricted field. The myopia induced by such intensive study necessarily involves disability to broader vision—a disability of which the patient is often completely unconscious—and we find the narrow specialist laying down the law as regards the problems of evolutionary philosophy in a way which even an elementary grasp of those portions of the subject lying beyond the limits of his own speciality would restrain him from doing.

In General Smuts we have a visitor to the domain of biology from very different fields of activity, and as he comes armed with credentials of the highest order—testifying to his intellectual power, to his honesty of purpose, and to his remarkable freedom from prejudice—it becomes of extraordinary interest to scan his vision of evolutionary philosophy, free as it is from the distortion and disturbance of true proportion which specialist concentration on little bits of the subject is so apt to induce.

The first four of the twelve chapters of "Holism and Evolution" are devoted to those fundamental concepts which underlie the general theory of evolution, to the ideas of space and time and matter, and to the cell and the organism. To the present reviewer, who believes that the lapse of time—with the truer proportions that distant vision gives—will show the figure of Charles Darwin towering alone above all others in the history of philosophy, it is particularly agreeable to see that General Smuts appreciates, in a way that the biological specialist so often entirely fails to do, the unique position occupied by Charles Darwin.

While emphasising in this introductory portion of the book the importance of increased precision of nomenclature, it is perhaps disappointing that the author has not handled the tangle in which so much modern discussion has become tied up in the misuse of the word 'space.' The conception of space is derived by a simple step from the sensory perception of the extension of material objects, by merely ignoring the material substance of which they are composed. That gives us the primitive idea of space, and this space is in its essence tridimensional. When the pure mathematician for his own purposes modifies this idea by removing or adding one or more dimensions, we are apt to forget that in doing so he has interfered with the fundamental conception of space as derived from our sensory experience of the material world. No harm is done in the realms of pure mathematics: the danger comes when such expressions as 'space' of one, or of two, or of *n* dimensions, are brought back into speculations regarding the material universe, for confusion of ideas is the immediate and inevitable result.

In the following chapters of his book the author develops his philosophy of Holism. "The close approach to each other of the concepts of matter, life, and mind, and their partial overflow of each other's domain, raises the question whether back of them there is not a fundamental principle of which they are the progressive outcome."

Evolution to the author is not the process expressed by that word taken literally—a mere unfolding of complexities already present—but is actually creative: "it creates both new materials and new forms from the synthesis of the new with the old materials." Surveying the world of Nature, the author sees its great characteristic in the tendency to the development of 'wholes.' To illustrate what he means by wholes, he cites the case of living organisms, each made up of constituent parts but yet possessing an individual specific character of its own. Although particularly obvious in the case of animals or plants, such wholes pervade all Nature—not merely the material world with its atoms, molecules, and chemical compounds, but also the immaterial world which includes human ideals and performances. Everywhere we find 'wholes' basic to the character of the universe, and "Holism as the operative factor in the evolution of wholes is the ultimate principle of the universe."

This, then, is the kernel of General Smuts's philosophy—that the universe is vitalised by a great driving force—its inherent tendency towards integration into more and more highly developed wholes, into the more lowly types seen in inorganic Nature, the higher types seen in living creatures, and finally the highest types of all on the artistic and mental and spiritual plane of existence. "Holism in all its endless forms is the principle which works up the raw material or unorganised energy units of the world, utilises, assimilates, and organises them, endows them with specific structure and character and individuality, and finally with personality, and creates beauty and truth and value from them." A great idea surely, and one which justifies the author in putting forward his claim that it brings us nearer "the monistic conception of the universe which is the immanent ideal of all scientific and philosophical explanation."

In a series of interesting chapters the theory just outlined is elaborated, one of the most interesting being that entitled "Darwinism and Holism." Here again full tribute is paid to the greatness of Darwin: "He has changed our whole human orientation of knowledge and belief, he has given a new direction to our outlook, our efforts and aspirations, and has probably meant a greater difference for human thought and action than any other single thinker."

Perhaps still more remarkable than the author's appreciation of Darwin is the fact that he has succeeded in maintaining his balance in regard to Mendelism, and has firmly placed it in proper perspective in relation to the general theory of organic evolution.

An acute discussion of Weismann and his work leads to the much-debated question of the inheritance of impressed characters, in which the author shows a distinct leaning towards accepting their transmissibility, incidentally testifying to the impression made upon him by Bower's discussion of the matter in relation to evolution in the vegetable kingdom. Repeatedly we come across the suggestion that such impressed or 'acquired' characters *may* be inherited. The position taken up, however, by those of us who feel constrained to keep such characters outside our evolutionary speculations, is not that we dogmatically deny that they *may* be inherited, but rather that we deny the existence of the overwhelming body of evidence that they *are* inherited, which we believe would inevitably be forthcoming were this the case.

An interesting feature in this chapter is that the author shows that he fully realises the prevalent error of thinking of small variations in detail by themselves, and stumbling over their selective value, instead of bearing in mind that these details are merely parts of a physiological whole and that the actual selective process deals with such complete individuals.

It is very true, and it is, in these days, really necessary to drive it home, that "there is no doubt that experimental evolution has, through its unavoidable limitations, greatly blurred the great Darwinian vision of organic evolution," and "natural evolution as distinguished from experimental evolution is a process, not of the hour or the day, but of geological time, and the results, consolidated through immemorial periods, cannot be repeated or rehearsed by short-dated laboratory experiments."

What Darwinism does not explain, or purport to explain, is the origin of the variations which form the raw material upon which natural selection works. To the present reviewer that raw material is provided by the instability or variability which is essential and inherent in the nature of life itself. To the author of Holism it is given by a universal tendency to undergo change in the direction of higher and higher integration.

As regards the general thesis of Holism, probably most men of science will find themselves in agreement with the author so far as the evolution of the universe as a whole, meaning by that the sum of all existence, is concerned. There must have been inherent in that from the beginning a creative power which has found its expression in all subsequent developments. Some, with General Smuts, will spell it Holism: some will spell it God.

Many, however, while accepting the argument for the universe as a whole, will feel doubts as to their being constrained to do so for its constituent parts. When dealing with any one of these we are no longer dealing with something that is absolutely self-contained: it now has an environment; and the doubt arises whether the environment, taken in conjunction with the instability which modern physics would appear to extend even to the minutest particles of 'dead' matter, may not have a moulding influence sufficient to account for evolution.

Enough has perhaps been said to achieve the purpose of this review—to direct attention to a remarkable and important work which should be read by all interested in the philosophy of the world in which they live. As will have been gathered, General Smuts' book is a step towards that merging together of science and philosophy which is bound to come at no distant date. Men of science and philosophers alike are aiming at the same objective—the unravelling of the meaning that lies behind phenomena.

Such basic ideas as space and time are no longer placed apart as *a priori* in their nature: it is realised that each is a simple development from sensory experience. The man of science believes that, with the foundations of his philosophy laid in experience, he is logically bound to keep in touch with experience throughout the whole process of building up that philosophy of the universe in which he lives. He realises that as he builds he must make use of every possible refinement of technique, whether of observation or of mathematical or other methods of working up the data obtained by observation. With both sets of workers striving onwards towards the same goal, it will not do for either to ignore any methods of technique that will help them on their way, and when once this is fully realised and a common technique adopted, we shall have at last a unified army marching onwards to the attack of ignorance, and it will be of little moment whether its banner is inscribed 'science' or 'philosophy.'

J. GRAHAM KERR.

The Geology of Siberia.

Fortschritte der Geologie und Paläontologie. Herausgegeben von Prof. Dr. W. Soergel. Heft 15: *Geologie von Sibirien.* Von Prof. Dr. W. A. Obrutschew. Pp. xi + 573 + 11 plates. (Berlin: Gebrüder Borntraeger, 1926.) 37·50 gold marks.

GEOLOGISTS will be deeply grateful to Prof. Obrutschew for his masterly summary of the geology of Siberia, since so much of its extensive literature is in Russian and therefore inaccessible to most western workers. His book will form a standard work of reference for the geology of northern Asia, owing to its concise summary of the available information, its clear discussion of the chief stratigraphical and tectonic problems, its admirable series of sketch maps, and its full bibliography.

Prof. Obrutschew divides Siberia into seven geomorphologic units, including the *Scheitel* of Suess, to which he refers as the *kern*, and therefore justifies the translation of the term as core or nucleus. He prefers to call this area the Sayan-Baikal Highlands, but Suess's explanation of its significance is confirmed, as the Jurassic and Kainozoic deposits upon it are horizontal. The most serious modification in Suess's interpretation of the structure of Asia is in connexion with the Altaids; Prof. Obrutschew shows that Suess has included in his Altaid Mountain Systems elements of different ages, trends, and origin. Some of the east Altai folds are Caledonian, and some, such as those of the Saur-Tarbagatai and the Tien Shan, are later. Prof. Obrutschew therefore excludes the Tien Shan ranges from the Altaids and restricts that term to the Altai, the Khirgiz folds, and the Siberian Hercynian movements. Suess's objection to the term Hercynian, however, still stands, and his suggestion of Altaid as the name for the widespread mountain system that was formed toward the end of the Palæozoic and includes American, European, and African as well as Asiatic mountains, remains unshaken by these restrictions.

In the long succession of marine deposits in Siberia most of the geological systems are represented, and they throw light on many problems. Thus, in reference to the current discussion upon climate and continental drift, it is interesting to note that the Siberian marine faunas from the Cambrian to the Upper Kainozoic all have features indicative of a northern zone. The fauna which suggests the warmest conditions is that of the Silurian, which is described as being rich in corals; but they are mostly either simple or Alcyonarian, and do not indicate such warm conditions as rendered possible in England the growth of the contemporary coral reefs and those of the succeeding Devonian. The Tethys once spread northward so far as the Siberian Islands, but its fauna there consisted mainly of ammonites, and was consistent with a moderately cool sea. In the Cretaceous, which is so often claimed as having had an Arctic tropical climate, the marine fauna was rich in Aucella, and the one coral quoted from Siberia is a simple form, a Microbacia, and these fossils might have existed in a sea as cold as the present Arctic Ocean.

The work follows quite different lines from the recent discussion by Prof. Argand of the tectonic of Asia. It is a summary of the facts with such discussion as is required to make them intelligible and interesting, and will be an indispensable book of reference in regard to Asiatic geology.

J. W. G.

Behind the Divining Rod.

The Divining-Rod: an Experimental and Psychological Investigation. By Sir William Barrett and Theodore Besterman. Pp. xxiii + 336 + 12 plates. (London: Methuen and Co., Ltd., 1926.) 18*s*. net.

SPECIALISATION in science, and the organisation of research, undoubtedly lead to rapid advance in the elucidation of particular groups of phenomena; but they are also responsible for systematic neglect of others. Thus there remain dark corners into which the investigators of the last century swept the trifles which they preferred to leave unconsidered.

For a hundred years after Cavendish had shown that a portion of atmospheric nitrogen, after being 'sparked' with oxygen, always remained uncombinable, chemists deliberately ignored this residuum; yet soon after Rayleigh and Ramsay turned their attention to it, the sky-signs of London were advertising by the glory of their colours that there was indeed something in it. When this has been possible in chemistry's diligently cultivated field, may we not hope to find much more lurking in those obscure places where none of the recognised sciences has as yet pegged out a claim?

The use of the divining-rod in the discovery of springs has long been looked at askance by men of science, and not altogether without reason. People who profess to be dowsers, though usually honest folk, are sometimes fools deserving the application of their rods to their own backs, as Prof. C. V. Boys hinted in these columns a quarter of a century ago. Occasionally they are pernicious paradoxers or, rarely, unblushing impostors; yet it must be acknowledged that none of those who essayed to prove that there was nothing but folly, perversity, and imposture in this method of water-finding, has succeeded in explaining the unquestionable facts. Every one who has had to do with the water-supply of country houses knows that dowsers do find water. To ignore problems for fear that their solution might involve methods beyond the domain of conventional physics is no more justifiable than would be the banning of research into protons and electrons lest it should lead the investigator beyond the sphere of Daltonian chemistry.

Many years ago Sir William Barrett defied scientific prejudice and took up the study of dowsing. He devoted so much time to the divining-rod in literature and in practice that a systematic statement of his results has been awaited with interest and curiosity. Unfortunately, he died without completing the classification and discussion of the mass of data in collecting which he had written, as the preface tells us, between 6000 and 7000 letters. Some months before his death, he had secured the co-operation of Mr. Theodore Besterman, with whom he discussed the whole subject, though for the actual arrangement and writing of the book before us the junior colleague accepts full responsibility.

Although the book makes very interesting reading, its arrangement is far less satisfactory than the orderly subdivision in the table of contents might suggest. Mr. Besterman devotes 250 pages to evidence of the reality of the finding of water (and incidentally other things) by the divining-rod, and only about 50 pages, many of them straying back to the earlier theme, to an attempt to explain the mechanism and rationale of the process. The work is divided into three parts. Part I. is entitled "Historical and Geological." The historical portion, after touching on the rise of dowsing in the fifteenth century, gives interesting details of the performances of three famous French dowsers for minerals and water and the tracking of criminals. It includes the strange case of the Abbé Paramelle, a water-finder who used no divining-rod and disclaimed any super-normal powers, yet the authors have decided that he was a dowser *malgré lui*. Much of the geological discussion strikes us as irrelevant and unnecessary, it being clear that none of the famous dowsers had any geological knowledge whatever and could not have located water by the lie of the sub-surface rocks.

Part II., though entitled "Experimental," consists of descriptions of the exploits of a large number of recent and contemporary water-finders similar to that given in Part I., with details vouched for by numerous well-known or highly respectable authorities. Three appendices cite other cases which might appropriately have come in Parts I. and II. Even the short "Part III., Theoretical," continues to adduce fresh evidence as to successful dowsers while setting forth the explanation of the action of the divining-rod arrived at by the authors. There is an excellent index, which will prove useful to students of the subject, and an extensive bibliography, which might have been improved by providing some indication of the size of the books cited.

As to the value of the whole discussion, Mr. Besterman says in his preface:

> "Whether the results justify this labour it is for the reader to decide; but should it be agreed that the ability to find hidden objects by other than normal means has been established, the question can hardly be answered otherwise than in the affirmative."

This is not happily worded, for it fails to define the critical term *normal*, and by extending the use of the divining-rod from the well-established case of water-finding to the detection of minerals, corpses, and even murderers, it makes room for the intrusion of false issues. Sir William Barrett probably went beyond the comparatively simple case of the divining-rod in water-finding because he hoped to reach in one stride an explanation which should include all kinds of cognition of objects undetectable by the 'five senses.' We agree that the evidence brought forward in the book proves the existence of a power in some people, of both sexes and of every age, race, and social position, of detecting underground springs of water which can neither be seen, heard, smelt, felt, or otherwise perceived by the vast majority of mankind. Further than this we are not prepared to go, nor do we think it necessary to seek more recondite explanations until all reasonable hypotheses for bringing the phenomena into line with the recognised or discoverable processes of Nature have been exhausted. The suggestion that radiation or vibration of some kind issuing from running water underground may be detected by the nervous system of the dowser in virtue of some hyperæsthesia is dismissed too curtly (p. 261) as "terminological perversity." The comprehensive explanation which Mr. Besterman tenders in the names of Sir William Barrett and himself (p. 267) to cover all cases of the dowser's detection of hidden things is:

> "The several categories of phenomena surveyed above appear to us to lead inevitably to the conclusion that no physical theory can cover the facts. In our view the phenomena of dowsing are due to the following causative chain of psychological and physiological happenings: a suggestion is received by the dowser's subconsciousness by means of a sensibility as yet unknown to us and therefore admirably named by M. Richet cryptesthesia; . . . the knowledge thus supernormally obtained can become conscious: . . . (1) if the person is one whose access to, and ability to become conscious of, knowledge in his subconsciousness is more continuous and complete than those of the normal person, the cryptesthetic suggestion received by his subconsciousness can almost simultaneously become conscious. . . . (2) By means of unconscious, automatic movements such as those which provide the phenomena of automatic writing. . . . Intermediately between these alternatives may be placed (3) those reactions of the subconscious suggestion which cause the phenomena which may be comprehensively described as the *malaise* of the dowser."

Here a fallacy may lurk, for if "a sensibility as yet unknown to us" is conjectured as conveying cognition to the subconscious whence it obscurely wriggles into the conscious mind, could the unknown sensibility not be as easily conjectured to appeal direct to the conscious mind? If cryptæsthesia is a "sixth sense," as M. Richet suggests, may it not be a sense capable of appreciating directly some physical property of the hidden object? This appears to be Prof. Richet's own view if we translate rightly his letter in Nature for Dec. 18 (p. 876) on the explanation of "spiritualistic" phenomena:

> "The hypothesis of unknown *vibrations* seems to me preferable. After all, why not suppose that reality emits vibrations? Do we not know of innumerable powerful vibrations such as electric and magnetic waves which are only revealed by special detectors and would pass unperceived without the use of these detectors?"

Thus Prof. Richet seems to countenance the idea which occurred to us, before his letter appeared, in reading Sir William Barrett's book, that the *malaise* of cryptæsthesia may be akin to that experienced by some people in thundery weather, which can reasonably be attributed to the action on the nervous system of the electric waves announced by wireless 'atmospherics' in advance of thunderstorms. Investigation must prove whether this is so, or if the recognised senses may in some people attain a state of hyperæsthesia and become capable of acting much more powerfully than under usual conditions. May not some people have a sense of smell (if it is smell) as highly developed as that of the dog which perceives in the dark outside a house the room in which his master is; or a sense of hearing or touch as fine as that of the bat, if that animal indeed navigates dark winding caverns by means of a natural power of echo-sounding?

It may be the prejudice of the student of measurable and calculable things which makes the hypothesis of cognition through the unconscious mind repugnant as an instrument of scientific research, or it may be ignorance of psychological methods which makes us incapable of being convinced by the arguments, while accepting the facts, brought forward in this book. Whether his explanation is right or wrong, Sir William Barrett deserves to be held in grateful memory for accumulating by his enthusiastic labour such a rich store of obscure facts. It is to be hoped that the book will inspire some open-minded investigator versed in physiology and adequately instructed in physics and psychology to make an exhaustive experimental study of the mechanics of the divining-rod and the concurrent physical and mental state of the dowser, with the sole object of seeing how it is done. Observers who take up the subject determined to prove that the whole thing is a piece of humbug, can of course discover nothing.

Hugh Robert Mill.

Our Bookshelf.

The Subject Index to Periodicals, 1922. Issued by the Library Association. *K: Science and Technology.* Pp. 136. (London: Grafton and Co., 1926.) 21*s.* net.

We welcome the appearance of this new part of the "Subject Index to Periodicals" dealing with periodical literature relating to science and technology published in the year 1922. The delay in issuing the volume, however, is very regrettable, the more so since there appears to be little improvement in this respect as successive volumes are produced. The interval of from four to five years which has to be made good by the user of the "Index" to bring his search up-to-date means a serious addition to his labours, and from the point of view of the publishers must undoubtedly tend to hinder an expansion of the subscription list to a degree commensurate with the value of the work offered. Since the interval is now so large, we are inclined to think, provided, of course, that the necessity of bridging the gap as soon as possible be kept steadily in view, that it would be better for the editors to proceed at once with the work on last year's journals so that this could be issued during the current year, and the annual volume thereafter be kept close on the heels of the material covered.

Apart from this, the present volume worthily maintains the reputation of former issues. Some 250 journals are indexed, and the entries are allotted to a very large number of headings covering a wide field, and arranged, as usual, in alphabetical order. Some readers may perhaps derive amusement from the juxtaposition of such headings as *Omnibuses* and *Onions*, but there is no doubt that an index of this description provides for much quicker reference than one arranged on any other system, and when the choice of headings, the allotment of the different entries, and the provision of cross-references, are carried out as carefully as they are in these excellent volumes of the Library Association, there is room only for satisfaction. The inclusion of a list and particulars of the journals indexed would be a great convenience.

Agricultural Research in 1925. Pp. vii + 174. (London: Royal Agricultural Society of England, 1926.) 2*s.* 6*d.* net.

The scope and purpose of this work is sufficiently explained by the following extract from the preface: "There is need for a new publication which would record, in a concise form, and in language easily understood by the non-scientific, but practical, man all the results of scientific work carried out, not only in Britain, but in other parts of the world, so far as it has bearing on agricultural practice at home." This preface is signed "Devonshire, Chairman Research Committee, Royal Agricultural Society of England." There follow five compilations by recognised authorities on each subject, dealing specially with research 'results' in veterinary medicine, soils and manures, animal nutrition, dairy husbandry, agricultural economics, and agricultural engineering.

No one can quarrel with the merits of the work; each section will certainly prove of interest to research workers in each particular field. But doubts may be expressed as to its intelligibility to the "non-scientific *but* practical man" (the italics are ours—the antithesis is, we hope, unintentional). Much of the language used implies some knowledge, not only of strictly scientific terms (such as metabolism), but also of ideas expressed in an ordinary language (*e.g.* energy) with which the 'practical' man is not familiar. Be that as it may, the names at the head of each section are a sufficient guarantee that the information given is trustworthy and that the praiseworthy objects of the leading agricultural society in Great Britain have been worthily achieved.

A Road to Fairyland. By Erica Fay. Pp. vii + 219. (London and New York: G. P. Putnam's Sons, Ltd., 1926.) 5*s.* net.

"A Road to Fairyland" is dedicated to "all children between the ages of seven and seventy," and the author has indeed provided a variety in her twelve stories in which something should please her clientèle at every stage within these limits of their years. Here and there we catch an echo of the folk tale; but the author has a subtle power of invention and a felicity of phrasing, as well as a humour, now delicate, now broad, which have carried her well on the way to success in the bold and risky undertaking of writing fairy tales. One feature in these stories may be held by some to be open to question. In most of them a moral is to be discerned, and sometimes it is explicitly stated in the good old-fashioned way at the end. The moral has long been condemned; but the healthy normal child does usually love a moral. It is infancy's equivalent to the triumph of virtue in the melodrama of days gone by. Of individual stories, the one with which the book opens, "The Princess," is perhaps the best. It exhibits a knowledge of human nature and a philosophy which makes the best of things that lift it to a higher plane. Palæontologists and metaphysicians with a sense of humour—if there are such—will appreciate the picture of a sabre-toothed tiger in Kent's Cavern being helped to his human dinner by a stalactite, which in so doing sacrifices its devotion to the absolute to gratify a desire for revenge on the human race. It will be seen that the author is something of a philosopher in the style of Andersen—no mean model.

Lime in Agriculture. 1: in Plant Nutrition, 2: in Animal Nutrition; a Handbook for Practical Farmers, Students, and Others. By Frank Ewart Corrie. Pp. xi + 100. (London: Chapman and Hall, Ltd., 1926.) 3*s.* 6*d.* net.

Lime deficiency is generally recognised as one of the main factors causing poor crop yields, but unfortunately in too many cases little or no attempt is made to remedy matters. This is partly due to a failure to realise the considerable improvement that is likely to be made by a judicious lime application, and partly to a lack of knowledge as to the best and most economical materials to use. The author has endeavoured to outline the problem in the simplest manner, emphasising the need for lime in both plant and animal nutrition, and supporting his remarks by reference to the results of modern research work. A very useful feature is a descriptive list of the various forms in which lime may be applied, as the expenses of carriage usually compel the use of the nearest source of supply. The benefits that crops derive from adequate lime are given, but no mention is made of the effect of chalk on heavy land in reducing the resistance offered to the passage of cultivation implements. On the animal side, the nutritive requirements of various classes of stock for lime are considered, together with the sources of supply, as milk, hay, and green fodders, meat and bone meals and fish meals. An appendix gives a series of illustrative analyses, including some of soils deficient in lime, various types of lime that may be used, lime deficiencies in rations, and the lime and phosphatic acid contents of foods.

Practical Photo-Micrography. By J. E. Barnard and Frank V. Welch. Second edition. Pp. xii + 316. (London: Edward Arnold and Co., 1925.) 18*s.* net.

Fourteen years have elapsed since the first edition of this book was published, but it is noteworthy, as the authors point out, that photo-micrography itself has made little advance during this period, though there have naturally been various modifications in the apparatus employed. The reason for this standstill is that microscopy has not advanced, for the best microscopes and miscroscopic objectives of twenty or more years ago are equal to any produced to-day.

After a brief summary on the microscope and its optical parts, illumination is dealt with. It seems scarcely necessary now to enter into such full detail respecting calcium carbide as is done, and no mention is made of paraffin and petrol mantle lamps, which in country districts may be of some service and are useful for printing on 'gas-light' papers in the absence of gas and electric light. The chapters on cameras, the use and manipulation of the microscope, colour screens and exposure, and photographic processes, are excellent, and the authors are able to incorporate many useful 'tips,' the result of their experience. Finally, the illustrations are adequate and clear, and a series of beautiful plates show what may be done by means of photo-micrography.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Future of the Natural History Museum, South Kensington.

IN reference to the expression on the part of Prof. Stanley Gardiner and others (see the *Times*, Jan. 13) of a desire for the assignment of an increased grant of public money to the institution known as "the Natural History Museum" (or more correctly as "the Natural History Departments of the British Museum"), will you allow me to say that whilst I share their wish and hope for this increased expenditure, I am strongly of opinion that no such increase should be made until the status, purpose, and organisation of this museum and other related institutions have been made the subject of a thorough and authoritative inquiry, and consequent recommendations by a Royal Commission appointed for the purpose? One or two matters which require the attention of such a commission have long occupied my thoughts, and I should like to indicate briefly what they are without entering at this moment into a discussion of details.

1. The most important point for such a commission to consider is, I think, the establishment of the Natural History Departments as an independent organisation—the "Natural History Museum" or "British Museum of Natural History"—under its own Council, 'Director,' and heads of departments, receiving an adequate grant from the Treasury, and reporting directly to a Minister of State and not to the 'Trustees' of the National Library and departmental collections of ancient and medieval art and anthropology.

2. Such a commission should give an authoritative statement of the scope of the Natural History Museum with a view to its immediate organisation and its future growth and development. No such agreed statement exists. There are two distinct purposes which should (it seems to me) be made by statute equally binding on the administration of the Natural History Museum, namely, (*a*) the 'edification' and instruction of the public by means of exhibition of carefully chosen and prepared specimens, and (*b*) the safeguarding and increase of the vast series of specimens of all kinds of living things from all parts of the world which are the indispensable 'documents' by reference to, and study of, which the biological sciences acquire far-reaching importance.

3. By judicious selection of the specimens to be permanently exhibited to the public with the most effective illumination and display, accompanied by skilful labelling and explanatory illustration, the actual floor-space now occupied by the public exhibits in Cromwell Road could be reduced to one-half of its present dimensions and the enjoyment afforded to the public in no way diminished. At the same time, the space thus set free could be used for the better accommodation of the reference collections and for the necessary 'work-rooms' required by the experts who continually add to the collections and maintain them in a proper state of conservation and order. They publish (under the Museum authority) accounts of new and important additions to knowledge. These publications are made by the staff of the Museum, and also by voluntary workers whose co-operation is welcomed by the official staff.

4. I will venture no further at the present moment than to suggest in the briefest terms some developments of the activities of the Natural History Museum which a Royal Commission might be asked to consider. Thus, for example, since there is, in the judgment of leading zoologists, a need for increased accommodation and expenditure in order to give needful help to the various branches of zoological science at the Natural History Museum, one is led to inquire as to whether it is reasonable to maintain there a Department of Botany, when so splendid an institute of botany is also maintained at the public expense at Kew Gardens. I will not attempt to state either the history or the justification of the existing arrangement. But it is obvious that, were the Botanical Department removed from the Natural History Museum to Kew, a very considerable space would be available for the expansion of the other departments of the Museum. Probably somewhat complicated legislation would be necessary to bring about the completion of Kew by the fusion with it of the Botanical Department of the Natural History Museum. The question worth consideration is whether such a fusion would promote the growth of botanical science.

5. A few words will serve to indicate some other developments which might be submitted to a commission. There is no truly *geological* museum in London. The Geological Department of the Natural History Museum has magnificent and invaluable collections of fossil vertebrates and invertebrates. But they are not there to serve the purposes of the investigator of geological phenomena. They are the records of palæontology. Many men of science would like to see a real museum of the 'geology' of the world, topographical and stratigraphical (not limited as is that of the Geological Survey), fully set out at the Natural History Museum. Another collection which has, by the chapter of accidents, been insufficiently developed at Cromwell Road is that of osteology—the skeletons of vertebrate animals. The fact that the Royal College of Surgeons has a fine series of osteological specimens has led to the relative neglect of this important branch of study by the Natural History Museum. Of late years efforts have been made to remedy this, but space, money, and time are necessary for the assemblage of such a comprehensive collection of osteological specimens as are needed by the modern zoologist, and could only be secured and preserved for reference and study by a great and wealthy museum.

I may just raise another question. Should there not be within the walls of the Museum a lecture-theatre to hold some 200 visitors, where lectures and demonstrations, by means of photographs and lantern, could be given at regular intervals by the Director and lecturers called in by him? The purpose of the lectures would be specially to illustrate and explain the contents of the public exhibition galleries. Copies of the photographs made for the lectures, might be sold at the book-stall of the Museum. The lectures would deal with such subjects as "The Classification of Animals," "The Origin of Species," "Geographical and Geological Distribution," "Variation," and "Heredity." Also "Recent Additions to the Museum" should be shown to the public at regular intervals by special lectures.

Lastly, as to expenditure on expeditions and collecting. The Natural History Museum has for many years given assistance to travellers and explorers by "working out" their collections, and often by purchasing specimens or whole collections. Prof. Stanley Gardiner is anxious to extend this line of activity. It is a difficult matter to deal with, since official and private interests and purposes are involved. There is

an obvious way by which important new collections and special specimens may be obtained for the Museum and for the public benefit. There was in 1912 (and possibly still is) in Berlin a Society of the "Friends of Natural History." They were rich men anxious to obtain new and important specimens for the National Museum of Berlin. In 1912 they put down £10,000 and sent five hundred negroes to Tendaguru, fifty miles from the coast of German East Africa, in order to collect the bones of certain gigantic extinct dinosaurs which had been discovered there. They brought these bones successfully, carefully packed in plaister and soft wrappings, to Berlin. Their discoverer, Dr. Fraas, named the largest of these great reptiles 'Gigantosaurus.' Its femur is ten feet in length. Tendaguru is now British, and further collecting of dinosaurs' bones is being carried on by an English party. It seems to me that zoologists should endeavour to set up a society like that of the German "Friends of Natural History." Such a society exists in Great Britain for the purpose of purchasing works of art for the National Collection. The society, by offering to *help* in expenditure for the national collections, might (and in art matters, I believe, does) induce the authorities to make desirable purchases. Our lovers of natural history should follow the example of the Berlin Society and of the English friends of art.

Chelsea, S.W.3.

The Genesis of the Great Nebulæ.

WITHIN the mesh of our local star-system are nebulæ of irregular shape, such as the Orion nebula, which are of only slight cosmogonic interest. Far beyond the confines of this local star-system lie the great nebulæ of regular shapes, spiral, elliptic, circular, etc., each of which is comparable in mass and size with our whole star-system. In the December (1926) issue of the *Astrophysical Journal*, Dr. Hubble paints a most fascinating picture of the system formed by the great nebulæ, and frames it in such convincing observational evidence that it would be difficult to reject it.

As seen in a telescope, the great nebulæ differ widely in shape, size, and brightness. But Dr. Hubble brings a mass of evidence to prove that differences in size and brightness between nebulæ of the same shape are almost entirely due to a distance effect. If all the nebulæ were put in a row at the same distance from us, it would at once be seen that nebulæ of the same shape all had approximately the same dimensions and luminosity, while even nebulæ of different shapes would exhibit only comparatively small ranges of dimensions and luminosity, especially the latter.

This makes it possible to estimate the distances of all nebulæ, even the very faintest, with fair accuracy. The faintest which can be observed photographically in the 100-inch telescope are of about 18th magnitude, and these must be at the amazing distance of about 140,000,000 light-years. Within this distance some two million nebulæ must lie. Dr. Hubble finds that these are fairly uniformly spaced at an average distance of about 1,800,000 light-years apart. To construct a model, take 20 tons of walnuts and space them at about 25 yards apart, thus filling a sphere of about a mile radius. This sphere is the range of vision of the 100-inch telescope: each walnut is a nebula containing matter enough for the creation of perhaps a thousand million suns like ours; each atom in each walnut is a solar system with a diameter equal to that of the earth's orbit.

With minor exceptions, all the different shapes of nebulæ can be arranged to form one continuous sequence, and this sequence is almost certainly evolutionary. Indeed, to my great gratification, it coincides almost identically, as Dr. Hubble remarks, with the evolutionary sequence I predicted for nebulæ, on purely theoretical grounds, in 1917 ("Problems of Cosmogony"). An initial sphere of gas gives place first to an oblate spheroid, and then to a lenticular figure. After this last configuration is passed, gas streams away from the nebular equator, generally in two symmetrical streams or arms. Granulations and condensations next begin to develop in these arms, each condensation ultimately forming a separate star, until finally the whole nebula is transformed into a star-cloud. Thus the great nebulæ prove to be the birth-places of the stars.

Long before I was able to trace out this complete evolutionary sequence, I had been able in 1901 to take a step in the reverse direction, and show that the stars had in all probability been born out of a uniform mass of tenuous gas by a process which I designated "gravitational instability." I calculated first that if all the matter in the present stars were uniformly spread out in space, it would form a gas of density about 10^{-23}. A dynamical investigation next showed that such a medium would be unstable, and that, as a consequence of this instability, it would break up, much as a jet of water breaks into drops, into condensations whose distances apart were a matter for calculation; on making the calculation these distances were found to be about equal to the actual average distance of the stars. Thus the single supposition that the stars had been born out of a uniformly spread mass of gas explained at one stroke the facts that the stars are of approximately equal mass, that they are spaced at approximately equal distances apart, and that these distances are what they are.

Dr. Hubble now finds that the nebulæ also are of approximately equal mass, that they are spaced at approximately equal distances apart, and that these distances are about 1,800,000 light-years. It is natural to inquire whether these facts cannot be explained at one stroke by the supposition that the nebulæ themselves came to birth as condensations produced by the gravitational instability of a still earlier and more tenuous mass of uniform gas. The test of the conjecture is of course by numerical calculation.

Dr. Hubble estimates that if the matter of the nebulæ were uniformly spread through space, it would form a medium of density $1{\cdot}5 \times 10^{-31}$. My theoretical formulæ ("Problems of Cosmogony," p. 219) show that instability would cause such a medium to form condensations at approximately equal distances of the order of 1,000,000 light-years. This is near enough to Dr. Hubble's observed distance of 1,800,000 light-years to make our conjecture seem reasonably probable.

If it is accepted, we have been able, with the help of the new knowledge gained by Dr. Hubble, to trace the evolution of the universe one step farther back than has been done before. We have in succession:

1. A uniform tenuous gas of density 10^{-31} and of diameter at least hundreds of millions of light-years.
2. Condensations developing in this gas at about a million light-years apart, and forming separate nebulæ with masses of the order of a thousand million suns.
3. Condensations developing in turn in the arms of these nebulæ, and forming stars with masses of the order of our sun.

To these, if my 'Tidal Theory' of the origin of the solar system (Memoirs, R.A.S., 1917) is accepted. may be added:

4. Condensations developing in the arms of gas pulled out from the stars by the tidal action of other passing stars, and forming bodies of planetary mass.

5. Condensations similarly developing in the arms of gas pulled out tidally from the planets, and forming bodies of mass comparable with the satellites of the planets.

This scheme covers five complete generations of astronomical bodies, having masses of the order of 10^{44} (or more), 10^{41}, 10^{34}, 10^{29}, 10^{25} gm. respectively, the birth of each generation from the preceding generation being through the agency of "gravitational instability" (*Phil. Trans.*, 199, A (1902), p. 49). It is based on *verae causae*, namely, the law of gravitation and the properties of the gaseous state of matter, and survives at each step the test of numerical computation and comparison.

J. H. Jeans.

Feb. 13.

Wave Mechanics and the Rotation of Homopolar Molecules.

In a letter to Nature (April 17, 1926, p. 555), J. C. Slater suggested an explanation of the 'quarter quantum numbers' used in describing the band spectra of homopolar diatomic molecules by assuming that, on the basis of the old quantum theory, the momentum was to be integrated about a half period only, since the molecule repeats itself after a rotation of 180°. This explanation finds its natural analogy in the new wave mechanics of Schrödinger, and leads to an interesting suggestion regarding the general solution of the wave equation.

In its usual form the wave mechanics presents a wave equation $(H-E)\psi=0$, where H is an operator derivable from the Hamiltonian function and E is the energy constant. It is assumed that only such solutions of the equation have a meaning for which ψ is a regular single-valued function vanishing on the boundaries.

The problem of the diatomic rotator has been solved by Schrödinger and others, who have found the following expressions for the energy and for Y where Y is that part of ψ depending solely on the space co-ordinates, in the present case upon the spherical co-ordinates θ and ϕ,

$$(1)\quad E=\frac{h^2}{8\pi^2 I}(j^2+j),\quad j=0,\ 1,\ 2,\ 3,\ \ldots$$

$$(2)\quad Y=P_{jm}(\cos\theta).(a_m\cos m\phi+b_m\sin m\phi),\qquad m=0,\ 1,\ 2,\ \ldots\ j,$$

where $P_{jm}(\cos\theta)$ is the Legendre function of the mth order.

To extend this solution to the case of a homopolar diatomic molecule, we have only to remember that by such we mean a molecule the two atoms of which are identical in mass and charge, that is, a molecule which repeats itself when it is rotated through 180°. In the wave mechanics this is clearly equivalent to the condition that only such solutions of the wave equation are to be accepted for which Y remains unchanged when $\theta\longrightarrow\pi-\theta$ and $\phi\longrightarrow\pi+\phi$. This will be the case when j is an even integer ($j=0,\ 2,\ 4,\ \ldots$), m being as before any integer odd or even.

The energy and wave function are still given by equations (1) and (2) subject only to the limitation that j shall have even integral values. It may be remarked that while we have treated the molecule as a rigid rotator, no new features are presented by taking into account the vibration of the nuclei, since such vibration does not alter the homopolar character of the system.

In applying the result just obtained to the band spectra of homopolar molecules, we notice that only bands involving a change in the electronic energy will be observed, and that if these are of the usual type possessing positive and negative branches, either the initial or the final state of the molecule must be non-homopolar. For example, if we take the excited state to be non-homopolar, we have for the energies

$$E_i=h\nu_e+hA'(j^2+j),\quad j=0,\ 1,\ 2,\ 3,\ \ldots,$$

$$E_f=hA(j^2+j),\quad j=0,\ 2,\ 4,\ 6,\ \ldots.$$

The selection rule is as usual $j\longrightarrow j\pm1$ or $j\longrightarrow j$, and the transition probabilities are given by the usual formulæ for dipole molecules. This leads to a set of band lines which correspond directly to those obtained previously by the use of quarter quantum numbers. While this is very satisfactory, a closer inspection shows that the theory is not in agreement with other features of the observed bands. Thus we should expect the zero branch to be given by the formula

$$Q_j=\nu_e-(A-A')(j^2+j),\quad j=0,\ 2,\ 4,\ \ldots,$$

whereas, for example, in the helium bands found by Curtis and Long (*Proc. Roy. Soc.*, A, 108, p. 513, 1925) the zero branch is very accurately represented by another relation, namely:

$$Q_j=\nu_e-(A-A')(j^2+j),\quad j=1,\ 3,\ 5,\ \ldots.$$

Furthermore, when j is allowed to have only even integral values, we obtain a specific heat curve which seems to be quite impossible, since the value of C_r/R rises to an abrupt maximum of about 1·5, thus giving a curve which in no way resembles the observed specific heat curve of H_2.

A way out of these difficulties may be found by employing a new postulate in the wave mechanics, namely, that, given the wave equation of Schrödinger, we shall seek such solutions to it for which the function $\psi\bar\psi$, rather than ψ alone, shall be a regular single-valued function where $\bar\psi$ is the conjugate to ψ.

This assumption, which we believe has also been suggested by Heisenberg, has much to recommend itself by being more nearly in accord with the spirit of the new mechanics, since the function $\psi\bar\psi$ seems to represent the electrical density, whereas the function ψ alone has no such physical meaning.

Applying this new assumption to the homopolar molecule, we are led to two independent solutions, the first of which is equivalent to the solution already obtained.

$$\left.\begin{array}{ll}(3) & j=0,\ 2,\ 4,\ \ldots\\(3') & j=1,\ 3,\ 5,\ \ldots\end{array}\right\},\quad E=\frac{h^2}{8\pi^2 I}(j^2+j).$$

These solutions, which are each complete in themselves and admit of no intercombination, seem to correspond respectively to the symmetrical and anti-symmetrical solutions found by Dirac and Heisenberg for systems composed of two or more identical parts.

The empirical relations found to exist among the lines of the helium bands by Curtis and Long (*l.c.*) may now be shown to be just those consistent with solution (3′), although the numerical values of the moments of inertia given by them must be increased by a factor of four.

S. Werner (*Proc. Roy. Soc.*, A, 113, p. 107, 1926) has observed recently a band spectrum of H_2 in the far ultra-violet. We find that the majority of the band lines may be arranged in P, Q, and R branches the positions of which agree with the lines derived from (3′) when we assume the final or unexcited state to be homopolar, an assumption which appears very satisfactory, since Werner's H_2 bands evidently correspond to the Lyman series of the H atom.

The band constants vary somewhat from band to band, but lead to a moment of inertia for the excited molecule of about 10×10^{-41} and for the unexcited molecule of about 6×10^{-41}. The value of the moment of inertia of the excited molecule is of the same order of magnitude as the moments of inertia found from some of the bands of H_2 in the visible region. Since the visible bands correspond to transitions in which both states of the molecule are excited, it is probable that in both states the molecule is non-homopolar, in which case we should continue to employ the usual formula for the diatomic molecule.

Equation (3′) leads to a specific heat curve for the homopolar molecule, which rises without a maximum asymptotically to the value $C_r/R = 1$. In the case of hydrogen the curve fits the experimental data rather well, although it rises somewhat too steeply in the region between 150° and 250° absolute and gives as the value of the moment of inertia of the molecule $6{\cdot}7 \times 10^{-41}$, in substantial agreement with the moment of inertia for the unexcited molecule found from Werner's bands.

We shall now give briefly the results we have obtained for other rotator systems by accepting those solutions to the wave equation for which $\psi\bar{\psi}$ is a regular single-valued function. For the simple dipole diatomic molecule two solutions present themselves:

$$\left.\begin{array}{ll} (4) & j = 0, 1, 2, 3, \ldots \\ (4') & j = \tfrac{1}{2}, \tfrac{3}{2}, \tfrac{5}{2}, \ldots \end{array}\right\}, \quad E = \frac{h^2}{8\pi^2 I}(j^2 + j).$$

As is well known, only the first solution (4) leads to a set of band lines in agreement with the observed band spectra of such molecules. A closer investigation seems to show, moreover, that (4′) has only a formal character and could only apply to molecules for which one could exclude *a priori* the possibility of their ever possessing an electronic angular momentum about the figure axis.

We have also considered the case of the symmetrical top molecule (*i.e.* a polyatomic molecule with moments of inertia $A = B$ and C) and find that the wave equation leads to two independent solutions for which $\psi\bar{\psi}$ is a regular single-valued function.

$$\left.\begin{array}{ll} (5) & \begin{cases} j = 0, 1, 2, \ldots \\ n = 0, \pm 1, \pm 2, \ldots \pm j \end{cases} \\ (5') & \begin{cases} j = \tfrac{1}{2}, \tfrac{3}{2}, \tfrac{5}{2}, \ldots \\ n = \pm\tfrac{1}{2}, \pm\tfrac{3}{2}, \pm\tfrac{5}{2}, \ldots \pm j \end{cases} \end{array}\right\},$$

$$E = \frac{h^2}{8\pi^2}\left[\frac{1}{A}(j^2 + j) + \left(\frac{1}{C} - \frac{1}{A}\right)n^2\right].$$

These solutions are each complete and allow of no intercombinations, and so far as can be seen the energy of a molecule of this type might be given by either (5) or (5′) but not in any case by a combination of the two. Equation (5) is exactly that already given by F. Reiche (*Zeit. für Phys.*, 39, p. 444, 1926) and by R. de L. Kronig and I. I. Rabi (NATURE, Dec. 4, 1926, p. 805) for the symmetrical top molecule, on the basis that the function ψ was to be regular and single-valued. On the other hand, by means of the Born-Heisenberg matrix mechanics, I have obtained two solutions to the problem which correspond exactly to the solutions given above (*Phys. Rev.*, 28, p. 318, 1926).

In the foregoing discussion of the symmetrical top molecule we have assumed that $\psi\bar{\psi}$ will remain unchanged for a rotation of the molecule of 360° about the figure axis as well as for a complete rotation about the precision axis.

If, however, the molecule has a symmetry element in the position of its particles, we must introduce further conditions. For a molecule which repeats itself after a rotation of $2\pi/k$ about the figure axis we find the two independent solutions,

$$\left.\begin{array}{ll} (6) & \begin{cases} j = 0, 1, 2, \ldots \\ n = 0, \pm k, \pm 2k, \ldots \end{cases} \\ (6') & \begin{cases} j = \tfrac{1}{2}, \tfrac{3}{2}, \tfrac{5}{2}, \ldots \\ n = \pm\dfrac{k}{2}, \pm\dfrac{3k}{2}, \pm\dfrac{5k}{2}, \ldots \end{cases} \end{array}\right\},$$

$$E = \frac{h^2}{8\pi^2}\left[\frac{1}{A}(j^2 + j) + \left(\frac{1}{C} - \frac{1}{A}\right)n^2\right]$$

where the absolute value of n is less than or equal to j in both cases.

It is with great pleasure that I thank Prof. E. Schrödinger for many suggestions and for many helpful criticisms during the course of the work. I hope to publish in the near future a more detailed paper covering the calculations.

Zürich, Dec. 23.

Refraction of Electromagnetic Waves round the Earth's Surface.

J. A. FLEMING (*Proc. Phys. Soc. Lond.*, 26, 318-333, 1914) reached the conclusion that the variation with height of the dielectric constant of the atmosphere would bend a ray sent out tangentially to the earth's surface so that its radius of curvature would be about four times that of the earth. Furthermore, he found that, if the atmosphere were constituted wholly of krypton, a horizontal ray would have a radius of curvature equal to that of the earth, on account of its greater density.

As the radius of curvature in air is comparable with that of the earth, we thought it possible that the angle of incidence of the wave on the Heaviside layer would be so affected as to make the apparent height of the layer too great. Although we find this effect to be quite negligible, we came across a point which may be of interest—namely, if electromagnetic waves sent upwards are to return, the effective value of the dielectric constant must change with height in a definite manner.

From recent investigations it appears that from 40 km. to 150 km. above the earth's surface the temperature rises from 220° A. to 300° A. We assume that this change is linear and that the constitution of the atmosphere remains unchanged. These two assumptions, combined with the values of density and height tabulated on p. 72 of Humphreys' "Physics of the Air," give to a fair approximation the following empirical law connecting density d and height h in kilometres:

$$d = 0\,0013\, e^{-0{\cdot}14h}.$$

The well-known relation between dielectric constant K and density, that

$$(K - 1)/(K + 2) \propto d,$$

combined with the equation for d, gives the empirical relation

$$K = K_0 + \rho e^{-ah},$$

from which the value of ρ is $0{\cdot}59 \times 10^{-3}$, taking $a = 0{\cdot}14$, and $K_0 = 1$.

Considering the earth as plane, it can easily be shown that a ray starting from the earth's surface at an angle of elevation ϕ_0 will become horizontal at a height y given by

$$-ay = \log_e [(\rho \cos^2 \phi_0 - \sin^2 \phi_0)/\rho].$$

This cannot hold unless $\tan^2 \phi_0 < \rho$, whatever may be the value of α. This means, in the case of the earth, that a ray starting at an angle of elevation of more than 1°·5 cannot return to the earth if the above law for K holds. If, on the other hand, the signs of both ρ and α are changed, rays at any angle would eventually return.

The equation, when we take account of the earth's curvature, is

$$\cos\phi/\cos\phi_0 = R[1+(1-e^{-\alpha y})\rho/2]/(R+y),$$

where ϕ is the angle of elevation of the ray at any point, y the distance of the point from the surface, and R the radius of the earth.

When the ray is parallel to the earth's surface $\phi=0$. Therefore

$$\sin\phi_0 = 1 + y/R - (1-e^{-\alpha y})\rho/2.$$

From this equation conclusions can be drawn similar to those obtained above when considering the earth's surface as plane.

We thus arrive at the result that the general condition under which a ray can return from the upper atmosphere is that the second differential of the dielectric constant with regard to height should be negative. In the case of the earth's atmosphere the density, according to the assumption given above, varies in such a manner that this differential is positive. The conclusion does not hold for rays at angles of elevation of less than 1° or 2°.

Melanism in the Lepidoptera and its Evolutionary Significance.

IN the interesting article by Dr. J. W. Heslop Harrison in NATURE of Jan. 22 on experiments with Lepidoptera, there appears the following: "Thus we are dealing with a case of evolution directed by the environment, and presumably, therefore, of the Lamarckian order. Naturally, this view has been strongly contested by the opponents of the Lamarckian position, but, let it be emphasised, not one of those so opposed has studied the subject in the field. On the other hand, field workers are unanimous in giving it vigorous support."

I do not underrate the importance of the work of Dr. Harrison, nor do I question the accuracy of his fascinating experiments. But I must confess that I cannot understand the reference to field workers in the passage quoted. Does not the question at issue here concern the interpretation of laboratory experiments? Let us admit that in the industrial areas a tendency for certain Lepidoptera to become melanotic has been clearly demonstrated. Harrison and Garrett have shown that feeding the caterpillars with metallic salts produces the same effect, and that this induced melanism is inherited. There is, however, no evidence in the experiments that a somatic change has produced a germinal change. On the contrary, the melanotic changes did not appear in the first generation treated, but in succeeding generations. It seems just as likely, therefore, that the germ plasm has been influenced before the soma. As Harrison states near the end of his article, the experiments "demonstrate . . . that the germplasm can be influenced by external agencies." They do not supply any further evidence in support of what is usually understood by the term "Lamarckism," although their importance in other directions will be far-reaching.

W. J. DAKIN.

The University, Liverpool,
Jan. 24.

IF reference is made to my original article, it will be found that in his letter Prof. Dakin simply repeats my own views, as he himself realises when he quotes from my concluding remarks.

This position I emphasise further in a paper with the title "Experiments on the Egg-laying Instincts of the Sawfly, *Pontania salicis* Christ., and their Bearing on the Inheritance of Acquired Characters; with some Remarks on a New Principle in Evolution," which appears in the current *Proceedings of the Royal Society* (B), the 'new principle' being seen in a differentiation of that governing the melanism work from those covered by the term 'Lamarckism.' In that communication, without any possibility of misunderstanding, I state: "Clearly such evolution as is pictured at work here is not of the Lamarckian order; most likely the influences at work act directly and simultaneously on soma and germ alike, or even on germplasm alone, and, indeed, the latter view obtains concrete support from the *Selenia bilunaria* work."

However, in my opinion and in that of many other workers, if a chemical substance ingested with the food can influence the germplasm, then the germplasm can be affected through the soma. In connexion with this I ask Prof. Dakin to consider, in particular, the relation between the two existing in plants, as demonstrated in plants raised from leaf-cuttings and by other vegetative means.

J. W. HESLOP HARRISON.

Changes in the Length of the Day.

THE article by Dr. E. W. Brown on "Changes in the Length of the Day" in NATURE of Feb. 5 cannot fail to attract attention. To avoid any possible misunderstanding I think I ought to explain that the references which Dr. Brown makes to my results refer to my paper, "A Solution of Ancient Eclipses of the Sun," published in the *Monthly Notices of the Royal Astronomical Society*, Dec. 1920, not to my paper entitled "Trepidation" in *Monthly Notices* for Dec. 1926, which Dr. Brown had not seen at the time of writing. In the latter paper I show that if we adopt $4''\cdot 8$ as the change in the apparent longitude of the moon in a century, due to any acceleration not recognised in the existing gravitational theory or to changes in the length of the day, the Greenwich meridian observations give $1''\cdot 36 \pm 0''\cdot 15$ as the corresponding change in the apparent longitude of the sun, thus confirming the result which Dr. Brown cites from my work on ancient eclipses. I also find that any correction to the assumed century accumulation for the moon requires a correction of 1/9·5 as much to the deduced accumulation for the sun, so that the latter term is very little dependent on the value obtained for the lunar term.

In the same paper I show that the fluctuations to which Dr. Brown refers are found not only in the longitudes of sun, moon, and planets, but also (1) in the amplitudes of the inequalities produced by the action of Venus in the motion of the earth and of Mars, and (2) in the motion of the equinox. These results are inconsistent with the theory which attributes the fluctuations to a variation in the rate of the earth's rotation. I also find that the Greenwich meridian observations give not 1 in 13·3 as Dr. Brown has assumed, but 1 in 9·5 as the ratio between the fluctuations of the sun and moon.

It is probably too early to give a final explanation of these interesting fluctuations, but it is clear that there is a fluctuation in the total action on the earth, which determines its mean motion, amounting to between one-third and one-fourth of the fluctuation in the action of Venus, but in the opposite direction, so that an increase in the action of Venus is accompanied by a diminution in the total action, and vice versa. This seems to imply something like an interchange of mass between the sun and Venus and perhaps between the sun and other planets. In other words, I think Dr. Brown was right when in 1914 ("Report of the British Association," pp. 319-21) he attributed the fluctuations to a surge spreading through the solar system, and I think he has too readily adopted the theories of others who have tried to explain them as changes in the length of the day.

On this subject I have expressed the conclusion: "We may therefore declare with confidence that while the earth's rotation may be affected by a secular retardation, it is certainly not affected by a fluctuation" (*Monthly Notices*, Dec. 1926, p. 163).

Rotation of Dielectric Bodies in Electrostatic Fields.

THE phenomenon of rotation of dielectric-surfaced cylinders between the poles of a Wimshurst machine, described by Dr. Richardson in NATURE for Feb. 12 (p. 238), and recently demonstrated by him, does not appear to differ in any essential feature from that exhibited by the old toy "electrostatic motor," consisting of several insulating spokes radiating from an axle, and each surmounted by a light celluloid or other ball. This rotated between oppositely charged knobs. The cause of rotation is presumably identical in both cases. The same result could doubtless be obtained by using a conducting surface broken up by insulating strips, as on the commutator of an ordinary D.C. motor.

CHARLES RECORD.

Technical College, Huddersfield.

Biological Fact and Theory.

I HAVE noticed that people who are good at solving cross-word puzzles are also very good at understanding those complex statements of Mendelian results. I am distressed at my inability to worry out cross-word exercises and also those F_1, F_2, etc., synoptical charts, for I feel I may be missing something that will help in an understanding of genetical problems. It would be comforting to know if there are other biologists who admit the same disability.

What, however, are the 'fundamentals of genetics,' and what is this 'whole discipline of biology' that is going to give us the key to the processes of development? Is breeding cats, and cocks and hens, and flies, and so on, such fundamental research? A 'gene' is, I suppose, a physico-chemical entity: at least, it *ought to be* such so long as we study development by chemical and physical methods. We know that it is something that grows, like a crystal of alum selects molecules of alum from its mother-liquor, or 'environment'—the two kinds of growth differ, of course, but let that pass. It selects materials from the nutritive environment and then it reassembles these materials in new chemical forms, but it also reassembles the chemical products in typical morphological constellations. How? This is *the* fundamental genetical problem.

Then a 'gene' has a quasi-independence even if it is 'linked.' It is interesting to see how genes retain their quasi-independent activities so as to continue to give us 'bar-eye' and 'spot' and 'plain' and 'red-eye,' for example, but still a red-eyed Drosophila is always a Drosophila, and so also with the four hundred other characters which presumably express the activities of as many genes. All the time we are looking at the morphological entity that we call Drosophila and 'bar-eye,' or 'red-eye,' or whatever it be, is always related to nervous system and muscles and wings and so on in a typical manner. Can there be a 'super-gene'; in other words, what is the physico-chemical mechanism that results in the development of Drosophila? This, I take it, is really what is fundamental to a knowledge of the developmental process. The appearances in the cell nucleus do not help us much, for no one now takes the crude view that the parts of the chromosomes *are* the genes. It is difficult to see how we shall advance along these lines by "building on the ample foundation already obtained by tens of thousands of breeding tests."

JAS. JOHNSTONE.

The University, Liverpool.

Illinium.

IN a copy of *Gaz. Chim. Ital.* (56, 862; 1926) received a few days ago, Prof. Rolla, of Florence, claims priority for the discovery of element No. 61, and proposes for it the name Florentium on the basis of a "Plico Suggellato" filed in June 1924. Prof. Rolla began his search for the element early in 1922 (see *Z. anorg. allgem. Chem.*, 157, 571; 1926). In making his claim for priority he was, apparently, not aware of the following facts:

In 1919 the University of Illinois and the U.S. Bureau of Standards entered on a joint investigation of the arc spectra of rare earth elements, using materials resulting from long-continued fractionations carried out at the University of Illinois. The results of this investigation were published in the U.S. Bureau of Standards Scientific Papers, 421 (1921), 442 (1922), 466 (1923). In the second of these papers, published at about the time that Prof. Rolla began his work and two years before his "Plico Suggellato" was deposited, Dr. Kiess, who carried out the spectrometric studies, reported 130 spectral lines which were common to the spectra of neodymium and samarium, in the samples submitted to him by Prof. Hopkins, and says, "These lines are of unknown origin and may belong to the missing element of order No. 61, coming between neodymium and samarium."

In January 1924, again five months before the deposit of Prof. Rolla's document, L. F. Yntema published an article, "Observations on Rare Earths. XV. A Search for Element 61," in which he gives five additional lines in the ultra-violet region, and repeats the statement that these probably belong to Element No. 61 (see *J. Amer. Chem. Soc.*, 46, 37; 1924). Finally, on the basis of still further work, including the finding of two X-ray lines of the *L* series, J. A. Harris with B. S. Hopkins announced the discovery of element 61 and proposed the name Illinium (see *J. Amer. Chem. Soc.*, 48, 1594; 1926).

In the light of these facts it would seem that the honour for the discovery of No. 61 belongs primarily to Prof. Hopkins, and that the element should be called Illinium rather than Florentium. This does not detract from the credit which Prof. Rolla should receive for his independent discovery of the element. Both Prof. Rolla and Prof. Hopkins realise that a large amount of additional work must be done before the element can be fully accepted.

W. A. NOYES.

ERRATUM.—We regret that the inscription appearing below Fig. 1 in Prof. John Percival's letter in our issue of Feb. 19, p. 280, was incorrectly printed. It should read: "Grains of wheat found in a vase on the site of a Sumerian house (3500 B.C.). Below are two rows: the upper row of the Sumerian grain, the lower of modern grains of Rivet wheat (*T. turgidum*) for comparison. (Natural size.)"

The Dinosaurs of Tendaguru.

By F. W. H. MIGEOD.

THE expedition sent out by the British Museum in 1924 to Tanganyika Territory to explore the dinosaur remains at Tendaguru broke down in the following year on the death of Mr. W. E. Cutler, the leader, in August 1925.

I was appointed leader in his place, and work was resumed on my arrival in November of the same year. Although the rainy season was coming on I decided to begin at once, and was glad to find that the rains were not heavy enough to be a serious impediment. Occasionally a digging might be flooded if the possibility of drainage was not very good; in which case it had to be baled out. I reckon that in this region continuous work all the year round is possible, and when I left to return to England in November last, I made arrangements for the digging to be continued in my absence. This naturally ensures a much bigger output in the twelve months.

FIG. 1.—Excavating a small dinosaur at Tendaguru.

Nevertheless, prospecting is limited to the dry season. One has only to walk about the country in the neighbourhood of Tendaguru hill after the grass is burnt to see how vast is this graveyard of dinosaurs. There is an area of perhaps three miles width east and west and ten miles north and south where they may be found. Denudation in the course of ages has removed the many strata of rock that ages piled up on their remains immediately after their extinction; and once again these bones lie close to the surface. Most of the damage to them has been done in quite recent years through the penetration of the roots of plants and trees. At the present day they lie at an average level of 700 ft. above the sea, and fragments on the surface commonly, though by no means always, give an indication of where bones may be dug for. Yet further, the stratum is not always an indication, for the dinosaurs I collected lay in several different kinds of ground, as in clays of more than one kind, some stratified and some much contorted, in loose sand and in harder sand rock.

Exploration in the twelve months under review was made in thirteen different sites round Tendaguru hill, and the yield of fairly complete dinosaurs was considerable. There is possibly enough material partly to reconstruct some two dozen skeletons representing a considerable number of different species, and work has been begun on them in the Natural History Museum at South Kensington.

Some of the specimens are naturally more interesting than others. My first dinosaur excavated was a small one (Fig. 1), but near it lay the skeleton of another which eventually required eighty carriers to take it down to the port of Lindi for final packing and shipment. This one when examined may prove to be a brontosaurus. As an indication of its size I may mention that the scapulæ were 48 inches long by 28 inches at the widest part. The greater part of the body had lain on a bank, but a small stream of the distant age, of course, when that dinosaur lived and died, flowed by and had disturbed the remains on one side, some of the bones showing strongly the destructive action of this water. The pelvis, dorsal vertebræ, and upper-limb bones were mostly clear of this stream, though at no great height above it; but mixed with the lower bones were numerous river-worn pebbles, and in the case of one rib two smooth pebbles were tightly jammed under it, causing it to bend and of course break, which could only have taken place after the flesh was decomposed.

Another skeleton, that of a slender animal perhaps forty feet long, was interesting from the fact that the tail when excavated lay out on the ground complete. It was fifteen feet in length, and near the body it had been pressed down into the mud some two feet deep. It had not been completely severed, but two vertebræ nearest the pelvis were hanging vertically, there were two or three at the bottom, and one or two nearly vertical again, the upper one joining the unbroken part of the tail. It was as if at death, or shortly after, some other huge dinosaur had set its foot on the tail in passing and pressed that part of it down into the mud. The dimensions of some of the bones of this dinosaur were: femur 51 inches, scapula 44½ inches, humerus 33 inches. The fore part of the body was on a slightly lower level than the hind part and tail, and the head and neck, which were displaced, were in such a position as if it had died in drinking or trying to drink water. The body lay generally on a very dark-brown clay which I found nowhere else, and a feature, unique so far as my own excavations were concerned, was that, enclosing the bones, was a green matrix which did not exist apart from the bones (Fig. 3).

Of the sites which I worked two were cuttings into hillsides, and accordingly progress was slower here than on the flat. The hillside excavation that was especially interesting in its results was the one which I made into the side of Tendaguru hill itself. This hill stands on the top of the deposits, and represents a piece of old land left rising up like an island, and undenuded comparatively. By getting well into the lower slopes I hoped to reach bones that had not been attacked by the roots of plants and trees. Two strata of bones revealed themselves here. The upper, in the greenish-grey clay, held some bones of large size belonging to a four-footed dinosaur with the fore limbs longer than the hind ones apparently, and which was possibly a brachiosaurus. A femur in excellent preservation measured 67 inches and weighed nearly 4 cwt. when plastered and ready for removal (Fig. 2). A humerus measured 60 inches with the ends incomplete. This grey stratum rested on another of sand, and here, at the meeting of the two strata, other bones, of an apparently different type of dinosaur, were found. On this lower level and near these latter bones lay a tree trunk 26 feet long, with peat adhering, and other finds on this lower level were numerous bi-valve shells of small size, and traces of lignite, as well as impressions of leaves.

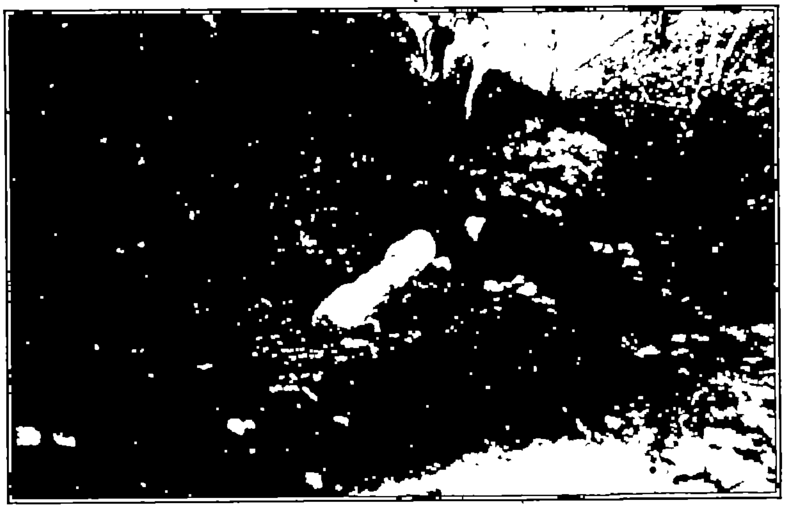

FIG. 2.—A femur 67 in. long, plastered and ready for removal.

FIG. 1.—Tail of a dinosaur in the foreground.

One of my sites furnished, in a space of 88 feet by 64 feet, a vast accumulation of bones which may prove to represent as many as twenty dinosaurs; and beyond these limits there were indications of many more. There was here what had the appearance almost of a battle-ground. We may figure to ourselves a region suffering a process of desiccation such as is going on in lands bordering on the southern Sahara at the present day, and coming on again in the Tendaguru region too. All living things flocked to the remaining pools of water for vegetation to eat and such water to drink as was left in the bed of a dried-up river; and they perished miserably one on the top of the other. A subsequent good rainy season could not help them as all was over. Sand swept over them and covered their remains, and the brief annual flow of the river in later years buried them in mud and sand. Here, as a matter of fact, there was very little clay. The deposit was principally sand, varying from a hardish yellow sandstone to loose and clean white sand.

Though this site did not furnish any bones of outstanding size, the biggest femur being 55 inches and biggest humerus 40 inches, it was interesting to find bones of quite young dinosaurs, one pair of femora measuring only 14 inches.

The position of the bones inclines one to the opinion that the dinosaurs here did not all lay themselves down to die in peace. There was much trampling by reptiles weighing several tons on others already dying or dead, which would cause some breakage of bones. There were bones which seemed to show breakage at or immediately after death, and while the muscles were still operative, one being a femur. Other bones, too, seemed to show fractures made during lifetime which healed without being set. The difference between these fractures and the clean ones made after fossilisation and due to earth tremors or stresses or to the recent action of vegetation, are readily apparent.

The dinosaur field of Tendaguru is by no means yet worked out. One might almost say it has only been scratched. That future work will yield many duplicates of the species already found is only to be expected, but it would be a serious scientific loss to the world if the area were exploited on lines of only taking certain bones and abandoning all others to perish from exposure simply because no immediate use can be made of the output. To cover up the bones again is not the same thing as leaving them untouched. In the circumstances, in view of the already considerable output, the preparation of which will take the British Museum some years, future field work at Tendaguru will be of a limited nature, and be carried on only in places where there is reason to believe in a possibility of different species being found.

Interionic Forces in a Completely Dissociated Electrolyte.[1]

By H. HARTLEY, C.B.E., F.R.S.

ONE aspect of the solution problem which has lately come into prominence is the effect of the forces acting between electrically charged ions. Faraday was much impressed by what he called "the enormous electric power of each particle or atom of matter," that is, the large size of the ionic charge. Helmholtz in his Faraday Lecture gave a calculation showing that the attractive force between the electrical charges associated with equivalent quantities of oxygen and hydrogen is 71,000 billion times greater than the gravitational attraction between these masses. It would seem obvious that such forces as these must affect the behaviour of ions. However, the difficulties in the way of a mathematical analysis of the effects of the electrical forces between ions in solution were considerable, and the problem was not attacked successfully until thirty years later.

Sutherland in 1907 was the first to suggest that electrolytes were completely ionised at all concentrations and that the interionic forces were in part responsible for the change in equivalent conductivity with concentration. In 1909, Bjerrum found that the molecular colour of chromium solutions was independent of dilution in the absence of complex ions, and explained his results on the basis of complete dissociation. He pointed out that the old difficulty with regard to the Mass Law would be removed if the interionic forces were entirely responsible for the variation of the equivalent conductivity and of the molecular freezing-point depression with dilution, as there would be no question of any equilibrium between ions and molecules.

The theory was supported by the additive properties of solutions of electrolytes and by the small change in the heat of neutralisation of strong acids and bases with dilution. In 1912, Milner succeeded in calculating the freezing-point depression of an electrolyte at different concentrations on the assumption of complete dissociation, by taking into account the change in potential energy of the ions on dilution. He pointed out that as a result of the electrical forces between them they would be so distributed that on an average unlike ions would be closer together than like ions, and that consequently work must be done in separating them on dilution. His results showed that in dilute solutions the change in the freezing-point depression with dilution could be ascribed entirely to the effect of interionic forces with a completely dissociated electrolyte.

In 1922, Debye and Hückel attacked the problem by fresh methods, starting from the same assumption of complete dissociation. By taking into account the unequal distribution of the ions, they were able to calculate approximately the freezing-point depression of salts of different valency types in very dilute aqueous solutions, although the calculated and observed values diverged at higher concentrations. But a matter of more immediate interest to us is their treatment of the conductivity problem on the basis of complete dissociation. They start from the same point of view as that of Milner, namely, that owing to the electrical forces between the ions there will be an excess of ions of opposite charge in the immediate neighbourhood of any single ion, as in the structure of a crystal of sodium chloride. Owing to the finite time which is necessary for the redistribution of the ions to take place round an ion that is in motion, there will always be an excess of ions of opposite sign in its rear, and hence it will be subject to a retardation when moving in an electric field. Further, as ions of opposite sign are moving in opposite directions and as both are supposed to carry with them a certain amount of solvent, the viscous resistance to the motion of the ions will be greater than if the solvent were at rest. Thus both these effects act in such a way as to reduce the speed of the ions. Assuming that at infinite dilution the ionic mobilities obey Stokes's equation, Debye and Hückel arrive at the expression

$$\frac{\lambda_0 - \lambda_v}{\lambda_0} = \left(\frac{K_1}{D^{\frac{3}{2}}} w_1 + \frac{K_2}{D^{\frac{1}{2}}} w_2 b\right)\sqrt{\nu m},$$

where the term $\frac{K_1}{D^{\frac{3}{2}}} w_1$ represents the fall in conductivity due to the electrical retardation and $\frac{K_2}{D^{\frac{1}{2}}} w_2 b$ that due to the electrophoresis of the solvent.

K_1 and K_2 are universal constants for all solvents at the same temperature.
D is the dielectric constant of the solvent.
w_1 and w_2 are valency factors.
b is the average radius of the ions.
ν is the number of ions per molecule.
m is the molecular concentration of electrolyte.

---

[1] Extract from the presidential address on "The Ionic Theory of Electrolytic Solutions," delivered at Oxford to the Science Masters' Association on Jan. 4.

Values of w_1 and w_2 for different salt types in which the anion and cation have equal mobilities are given in the following table. w_1 varies with the relative mobilities of the two ions; w_2 is independent of them.

VALUES OF VALENCY FACTORS.

Salt Type.	w_1.	w_2.
KCl . . .	1	1
K_2SO_4 . . .	4·24	1·41
$MgSO_4$ . . .	8	2

It will be seen that the above equation is in general agreement with the experimental results for strong electrolytes, as the fall in λ is proportional to the square root of the concentration, and is dependent on the dielectric constant of the solvent and on the valencies of the ions. The best test of the theory is to see how nearly the equation enables us to calculate the conductivity of a salt in different solvents. The observed and calculated results for potassium iodide are plotted in Fig. 1, the values of b required being calculated by means of Stokes's equation from the mobilities of the ions at infinite dilution. In water and methyl alcohol the calculated slope of the λ_c/λ_0 curve is greater than the observed slope; in ethyl alcohol and acetone the agreement is very close. The salt was chosen at random; others would have given better agreement in some solvents and worse in others, but looking at the results generally, it is a striking achievement that Debye and Hückel's theory is able to predict so closely the variation of the equivalent conductivity in dilute solutions in different solvents from a knowledge of the physical properties of the solvent and the mobilities of the two ions at infinite dilution.

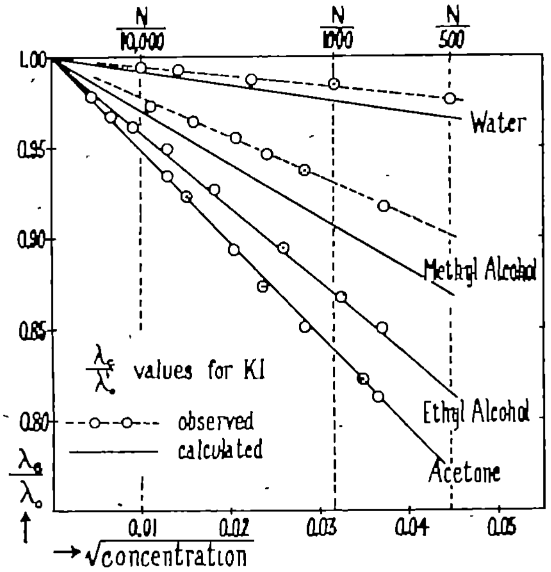

Fig. 1.

The mathematical theory is not yet in a final form even for dilute solutions; it takes no account of the changes in the solvent due to the high pressures produced locally by the electrical attractions between the ions, or of the change in the dielectric constant with the concentration of electrolyte. There is, too, some uncertainty as to the exactness with which Stokes's equation is obeyed; nevertheless, in its present form it gives us ample support for the belief that strong electrolytes are completely dissociated in dilute solution, and that the interionic forces may be responsible for their changes in properties with dilution.

Even, however, in dilute salt solutions, specific chemical interaction between the ions may be of importance, in addition to the normal electrical attraction between them. It is true that in dilute aqueous solutions there is a surprisingly close agreement between the behaviour of salts of the same valency type, although the salts of mercury form a striking exception to the rest, but when we pass to non-aqueous solvents with a lower dielectric constant, the purely physical aspect of the ionic relationship becomes more limited in its application, while the specific interaction of the ions begins to play a more important part. For example, in water the slopes of the equivalent conductivity curves of uni-univalent salts are nearly the same, while in methyl alcohol the results are far less regular; most nitrates have a different slope from that of the chlorides, and the values for silver nitrate fall much more rapidly than those for any other salt.

These differences are too great to be accounted for, on Debye's theory, by differences in the sizes or relative mobilities of the ions; and they indicate in some cases incomplete dissociation owing to interaction between the ions. With divalent ions the discrepancies in non-aqueous solvents are still more marked. In methyl alcohol, calcium chloride and perchlorate are normal in slope while calcium nitrate behaves like a weak electrolyte; with zinc, on the other hand, the perchlorate and nitrate are normal while the chloride is abnormal. Whether this is due to the formation of complex ions or of molecules is not yet known, but it is evident that in dilute non-aqueous solutions the specific interactions of the ions—in fact, their chemical affinities—may dominate the situation.

Obituary.

Sir George Greenhill, F.R.S.

The death of Sir George Greenhill will be greatly regretted by some generations of Artillery officers who were instructed by him in the mathematics of their profession as they passed through the 'Advanced Class' of the school at Woolwich which has had several names but is now known as the Artillery College. When the present writer joined that class in the spring of 1880, Greenhill had already been the mathematical professor there for several years. He went there after a short service at Coopers Hill and followed in succession Bashforth, Hirst, and Niven.

Good judges have been of opinion that Greenhill excelled in the application of dynamics to the problems of everyday life. The questions which, during many years, he contributed to test the candidates for the Mathematical Tripos and other examinations at Cambridge give ample evidence of this. They were concerned largely with the motion of trains and ships, and were recognised as being more in correspondence with actual facts on the engineering side than the academic type of question that had been previously in vogue. He was thus, clearly, the right man in the right place at Woolwich. He was able to treat artillery problems from the engineering point of view and to inspire his pupils to get as far as possible down to the actual facts of gunnery.

During the whole time that Greenhill was at Woolwich, more than thirty years, he was engaged in original investigations both pure and applied. In pure, he had a great liking for the elliptic functions, based on admiration of the classical works of Abel and Jacobi. His best work here had to do with the difficult subject of complex multiplication. In this and in similar investigations he was never satisfied with *theoretical* solutions. Abel having shown that certain equations could always be solved in radicals, Greenhill laboured actually to exhibit such solutions, and in this he was very successful. This was promptly recognised abroad, and his papers on the subject were translated into foreign languages. He was also concerned with the importance of having tables of theta-functions calculated. One of his last acts was to inspire Col. Hippisley, R.E., to carry out this work, which had been in abeyance since the death of Henry Stephen Smith.

Greenhill's leaning towards numerical results from complicated equations was assisted by uncommon algebraical power, which is constantly in evidence in his long series of papers in the *Proceedings of the London Mathematical Society*. The only book that he wrote that was entirely on pure mathematics was his " Differential and Integral Calculus " (1885). In this he is content to obtain results that are necessary for the practical applications. He had no liking for the modern refinements which are based upon the theory of functions. He was wont to speak of these as being " the morbid pathology " of the subject. He was aware, no doubt, that this " morbid " work had to be done by some one, but he was frankly out for practical applications, and was content to be in the company of many of the mathematical physicists of the day who, for example, use Taylor's theorem in practical questions and have little sympathy with a series of lectures on the cases in which Taylor's theorem fails.

Greenhill's " Applications of Elliptic Functions " is a work which exhibits many new results and much algebraical facility in getting out actual numbers. The " Hydrostatics " (1894) is probably his best book, as it is distinctly a new departure. Before its appearance the text-books were mostly on familiar academic lines and treated hydrostatic machines from a diagrammatic point of view. Greenhill's work deals, on the other hand, with the machines actually in use. He spared no pains to get down to reality. The *Transactions* of various institutions of naval architects were ransacked to supply him with problems old and new and their practical solutions. This material is arranged, described, illustrated, and treated by a consummate master of the subject. The result is a book which is unique and of exceptional value to all those who look for information on practical hydrostatics and pneumatics. It has met, it is believed, with universal approval.

Although he drew much of the material for this book from the work of others, Greenhill himself made considerable contributions to the subject. He wrote the article on hydromechanics for the " Encyclopædia Britannica." He defines it as the science of the mechanics of water and fluids in general, including fluids both in equilibrium and in motion. He made several contributions to the publications of the Institution of Naval Architects. In one of these (*Trans.*, 1894) he gave a remarkable demonstration of the theorem of Leclert which expresses the radius of curvature of the curve of flotation of a ship in terms of the radius of the curve of buoyancy, the volume of displacement, and the moment of inertia of the water-plane. It is accompanied by geometrical theorems, of much elegance, connected with stability. In another paper (*Trans.*, 1888), he writes upon the action of the marine propeller. Rankine (1865) assumed that the propeller impresses change of motion upon the water without change of pressure except such as is caused by the rotation of the race. Greenhill takes the converse view and assumes that it is obtained by change of pressure, the only changes of motion being the circumferential velocity due to the rotation of the screw, and a sufficient sternward momentum to equalise the radial and axial pressures.

Greenhill's most important contribution to practical gunnery appears to have been in regard to the rifling of ordnance. The first rifled gun-barrels came from the hands of two Nuremberg men, Kottee (1520) and Danner (1552). There exists at the Rotunda, Woolwich, a muzzle-loading barrel, dated 1547, rifled with six fine grooves. Robins, Copley medallist in 1746 of the Royal Society, experimented with rifled guns and elongated shot in England, but the question did not come seriously to the front until after the Crimean War, when the increased muzzle-velocities and the high pressures in the powder chambers and barrels caused the subject to be urgent. Armstrong's firm, and in particular Capt. (afterwards Sir Andrew) Noble, was the pioneer, and by proposing an increasing twist in the rifling from the powder chamber to the muzzle, directed the attention of the world of science to the problem. Greenhill worked at the subject independently. He established that the pitch of the rifling necessary to keep a projectile in steady motion is independent of the muzzle-velocity, of the calibre, and of the length of the gun ; depending principally on the length of the shell and on its description, so that, for similar projectiles, one pitch would do for all guns. The importance of this work and its value to Great Britain are beyond all question.

In gunnery Greenhill, at Woolwich, did much to mprove the application of the results of Bashforth's experimental work. In external ballistics he did not do anything comparable with the pioneer work of the latter, who laid a foundation stone which, through the years, has never been appreciably disturbed by the workers in any country of the globe.

The War, which disclosed many new problems, found Greenhill in retirement. The questions came before other brains and hands, and enormous progress has been made in every branch. The last occasion upon which he was much in evidence was during the meeting of the British Association and of the International Mathematical Congress at Toronto in 1924. On the passage out in the *Coronia* he was observed to be suffering and failing generally. He was a pathetic sight as he moved slowly about the boat. It will be remembered that he could not be found when the company arrived at Montreal. In answer to a telephone call he was not reported at Toronto, and real anxiety at once existed as to what had befallen him. This lasted for several days until it was discovered that he had really gone on straight to Toronto without telling any one of his intention and without reporting his arrival in that city officially. He was one of the few men of science at the meeting who had accompanied the Association in 1884 when it met at Montreal, for the first time in Canada, under the presidency of the late Lord Rayleigh. He had in his possession a photograph of a group of men taken on that occasion, on the outward voyage. It caused much interest, as it put in evidence the antiquated appearance that a group taken forty years ago can exhibit.

Greenhill was always somewhat eccentric, and as he became older increasingly so. Many of his colleagues or pupils who have travelled with him will recall that he was prone just to catch his train, so that he frequently just missed it. This, of course, is not an eccentricity which works well for the fellow traveller. In the earlier years he was distinctly sociable, certainly so at Woolwich. Later he became less so, and other points in his character—such, for example, as not giving a direct answer to a question—were accentuated. These peculiarities of thought and mind, which were constantly in evidence in social circles, appear to some extent in his mathematical writings and letters; also particularly in the reviews for which he was responsible in Nature and other periodicals. He was obsessed by the idea that mathematicians were not sufficiently engineers and were too much addicted to the philosophical side of their subject. Scientific engineers have been apt to regard him as being unpractical. Undoubtedly he stood somewhere between mathematicians and engineers, and was probably more of a mathematician and less of an engineer than the late Prof. Perry.

Greenhill's mathematical ability was recognised throughout his life. He was second wrangler in 1870, Pendlebury's year, and was bracketed with the latter for the Smith's Prize. He became a fellow of the Royal Society in 1888 and served in the Council in 1896. He received its Royal medal and also the de Morgan medal of the London Mathematical Society. He was corresponding member of the Paris Academy of Sciences and Officier d'Académie, and a foreign member of the R. Accad. Lincei. Young men who evinced a liking for mathematical research always received encouragement from him when he came across them. This was particularly so when it was a case of one who had not been through the usual scientific 'mill.' By such he is gratefully remembered. P. A. M.

Dr. C. D. Walcott.

Geologists and palæontologists mourn the loss of Dr. Charles Doolittle Walcott, who died on Feb. 8. For the last half-century he had occupied a foremost place in research in North America, and his discoveries in the older Palæozoic rocks had excited universal interest and admiration. At an age when most workers begin to need some repose, he continued his investigations with unabated vigour, and he was active in the pursuit of science almost to the end.

Charles D. Walcott was born in New York Mills, Oneida County, New York State, on Mar. 31, 1850, and was descended from New England settlers who had emigrated from Shropshire in the seventeenth century. When still at school at Utica he had already developed an interest in science, and at the age of thirteen he began to collect systematically both fossils and minerals. From school he proceeded to the Utica Academy, and eventually started life as clerk in a hardware store, where he acquired a practical business training which he always felt had been a real advantage in his later career. At the same time all his spare energies were devoted to scientific studies, and his discovery of Cambrian and Ordovician fossils near his home caused him to resolve that he would spend his life so far as possible in investigating the oldest fossiliferous rocks of the North American continent. In 1871, when visiting Indianapolis, he was encouraged in this resolve by Prof. E. T. Cox, who was at that time making a geological survey of the Indiana coalfields. Walcott therefore abandoned commerce, and spent the next five years on a farm at Trenton Falls, where he arranged to do a certain amount of manual labour in return for his board and lodging, and kept the rest of his time for study and field-work. In 1873 he sold his Trenton fossils to the Museum of Comparative Zoology, Harvard University, and would at the same time have gone to pursue a course of study under Prof. Louis Agassiz, had not that great naturalist just died. He had already discussed his plans for future research with Agassiz, and had decided that one of his main endeavours should be to determine the nature of the trilobites. He began by making polished sections of specimens from the Trenton Limestone, and thus discovered the first evidence of the branchial apparatus and the limbs in this group of fossils.

At last, in November 1876, Walcott found a congenial official appointment which enabled him to start his life's work in earnest. He became assistant to Prof. James Hall, the well-known State Geologist of New York. For three years he continued his researches while discharging the routine duties of this position, and in 1879 he entered a still wider field as assistant in the United States Geological Survey, which was then directed by Clarence King at Washington. He began his new official work by studying the geology of the high plateau of southern Utah and the country so far as the bottom of the Grand Canyon of Colorado. He then joined Arnold Hague in the survey of the Eureka mining district in Nevada, and in investigating the Palæozoic rocks of central Nevada. In 1882 he added to his other duties the identification in the Museum at Washington of all the Palæozoic fossils collected by the Survey; but he still continued his special studies of the Cambrian and earlier fossiliferous formations. After several promotions, he became director of the United States Geological Survey in 1894, and retained this appointment until he was elected secretary of the Smithsonian Institution in 1907. His business aptitude enabled him to reorganise the Survey and associated services on a more satisfactory basis than before, and he so gained the confidence of Congress that the appropriations for scientific work were much increased. For ten years from 1897 Walcott also acted as assistant secretary of the Smithsonian Institution in charge of the National Museum, and from 1902 until 1905 he was chief administrative officer of the newly founded Carnegie Institution of Washington.

Administrative duties never appeared to reduce Walcott's powers of research, and during the whole of his career he published in rapid succession papers and memoirs especially on the early Palæozoic fossils, which were always important—often startling—additions to knowledge. His works on the Cambrian faunas of North America and China are noteworthy as showing how varied was the life of the earliest geological period of which we have any satisfactory knowledge, and they will always remain classic. His discoveries of fossils in the still earlier Algonkian rocks of North America are pioneer contributions to a subject on which palæontologists eagerly await more information. His recognition of fish-remains in the Ordovician rocks of Colorado, at first received with scepticism, has now been confirmed by similar discoveries in other parts of North America.

Walcott was especially successful in finding impressions of soft-bodied organisms in the Algonkian and Cambrian formations—organisms which theoretically must have existed in immense variety before the habit was acquired of secreting hard parts which were capable of preservation as ordinary fossils. So long ago as 1898 he published a memoir on peculiar structures from the Middle Cambrian of Alabama which he regarded as the imprints of medusæ. In 1914 he described other structures from the Algonkian rocks of Montana which he interpreted as representing a very varied assortment of calcareous algæ. Almost every year after he became secretary of the Smithsonian Institution he spent the summer in studying the Cambrian formations of the Rocky Mountains in British Columbia; and in the Burgess shale of Mount Stephen he made a great collection of exquisite impressions of soft-bodied animals, previously unknown, which he described as primitive crustaceans, holothurians, annelids, and medusæ. There are still differences of opinion as to the success with which Walcott interpreted these several remarkable discoveries; but all are agreed that they add immensely to our means of studying the dawn of life on the earth, and make us hopeful of eventually finding at least some really generalised ancestors of several of the groups of invertebrate animals.

Walcott was especially fortunate in his home life, and both his first wife and the present Mrs. Walcott were ever sympathetic and helpful in his work. His unwearied industry was sustained until his last illness, and the joy of research always sufficed as recreation and relaxation from the arduous duties of administration.

Walcott naturally received many honours both at home and abroad. He was president of the National Academy of Sciences from 1917 until 1923, and received the Hayden medal from the Philadelphia Academy of Sciences. He was a foreign member of the Geological Society of London, and was awarded the Bigsby and Wollaston medals by that Society. He was also a corresponding member of the Royal Geographical Society. On his last visit to England in 1909 he received the degree of Sc.D. from the University of Cambridge. He was a corresponding member of the Academy of Sciences, Paris, and was awarded the Gaudry medal by the Geological Society of France. He was also a corresponding member of many other societies and academies on the European continent. The value of his work was indeed widely acknowledged by his contemporaries, and his researches will always be appreciated as remarkable pioneer efforts to understand some of the earliest phases of the geological record. A. S. W.

WE regret to announce the following deaths:

Mr. Francis Campbell Bayard, president in 1898–99 of the Royal Meteorological Society. At his home at Wallington, Surrey, he equipped a meteorological station and maintained regular observations there from about 1890 until last year. He died on Jan. 22, at the age of seventy-five years.

Dr. F. H. Knowlton, geologist on the United States Geological Survey since 1907, known chiefly for his work on the fossil flora of North America, on Nov. 22 aged sixty-six years.

Lieut.-Col. Henry Mellish, president of the Royal Meteorological Society in 1909–10. He maintained a climatological station at his home at Hodsock Priory, Notts., and had an unbroken series of observations for the past fifty years. He died on Feb. 2, at the age of seventy years, immediately after taking the morning observations.

Miss Matilda Smith, associate of the Linnean Society, who contributed many drawings to the *Botanical Magazine*, to Hooker's "Icones Plantarum," and to other works, and was associated for more than forty years with the Royal Botanic Gardens, Kew.

News and Views.

During the past few days, considerable prominence has been given in the Press to the appeal issued by the National Union of Scientific Workers to all men and women in Great Britain qualified in science to state their views on the possibility and desirability of building up a body which can claim to be fully representative of their varied interests. They are not asked to join the existing organisation, although they are being given an opportunity of stating if they believe that around the existing nucleus such a body can be built up. The appeal is issued over the signatures of eminent scientific workers, leaders in industry, and public men of differing political views. In addition to the principal signatories, a hundred men and women, representative of every branch of science and nearly every scientific institution in Great Britain, are giving their support to the movement. Such support should go far to remove some of the prejudices which have arisen against this body, mainly due to the title which was chosen by its founders. The words "National Union" are sufficient to arouse in some minds the fear that members of such a body must necessarily contemplate the ultimate use of the strike weapon in enforcing their demands. It is well, therefore, that it is definitely stated in the appeal that recourse to this method of redressing the grievances of scientific workers would be ineffective and absurd. What the society does hope to do, however, if it becomes fully representative, is to mould public opinion to bring about a greater appreciation of potentialities of science and thereby create a greater demand for scientific services, and also to instil the knowledge that this demand can only be met adequately by making the conditions of service sufficiently attractive to bring to the pursuit of science the highest intellectual types in Great Britain. Above all, it aims at producing in scientific workers themselves a consciousness of their functions as citizens, to the end that they will endeavour to take a more active part in the control and the direction of the affairs of a type of civilisation for the evolution of which science is chiefly responsible.

Lord Balfour received a deputation on Feb. 16, representative of various societies and authorities interested in the pollution of the rivers and estuaries of Great Britain, which urged the appointment of a central committee with power to co-ordinate the investigations and efforts now being made to cope with this problem. The need for legislation from the aspect of water-supply, inland and esturine fisheries, public health, and the amenities of the countryside was indicated, and a memorandum by a joint committee of the British Waterworks Association and the Salmon and Trout Association submitted. Lord Balfour acknowledged the very complete way in which the deputation presented its case. He pointed out that the central authority would require executive powers to reserve and purify waters and override other conflicting interests. He stated that co-ordination and advice alone would, in his opinion prove insufficient; what is wanted is more knowledge of the various pollutions. With each manufacture producing its own particular type of evil, each requires its own separate remedy, which can only be found by research. The Government is prepared to supply financial resources so that these necessary investigations may be carried out. The need for more knowledge to provide a firm basis for adequate and equitable legislation was emphasised in our leading article of Jan. 1. This is clearly the view now held by the Government. Compared with the issues at stake, the cost of research is minute, and it is the only practicable insurance against wasteful expenditure in attempts to cope with the purification of noxious effluents.

H.M. the King has signified his intention of visiting Cardiff during Easter week, accompanied by H.M. the Queen, to open the National Museum of Wales. This will be the fulfilment of a hope expressed by His Majesty when he laid the foundation-stone of the Museum in 1912, that he would be able to open the building then inaugurated. The building which will be formally opened by the King includes the magnificent south front, containing the great domed central hall, and a series of galleries on the east and west sides, erected at a cost of a quarter of a million pounds. It represents but part of the complete scheme. The recent donation of £35,000 by Lord Buckland will enable the council of the Museum to proceed with the erection of a further series of galleries on the eastern side, and it is estimated that the building, when completed, will have cost not far short of a million pounds. The interest which the King and Queen have maintained in the progress of the institution, culminating in their visit for its formal opening, should go far in emphasising to the people of Wales the importance of their national Museum and in stimulating their support to enable the full scheme to be brought to fruition.

At the meeting of the Royal Astronomical Society in June of last year, the president, Dr. J. H. Jeans, offered to endow an annual lectureship. This was gratefully accepted, and following the wish of the donor, it was called the George Darwin Lectureship. The deed of gift allows considerable latitude in the time of delivery of the lecture and in the choice of the lecturer, although it was suggested that the lecturer should preferably be resident outside the British Isles, and that the gold medallist of the year might often be a suitable lecturer. This year the Gold Medal of the Society was awarded to Prof. Frank Schlesinger, Director of the Yale University Observatory, and at the annual general meeting of the Society on Feb. 11, the president gave the usual address on the award of the medal. Prof. Schlesinger was prevented by illness from attending the meeting, but he has now arrived in England and will give the first George Darwin Lecture at the next meeting of the Society on Mar. 11, when also the Gold Medal will be presented to him. The title of his lecture will be "Astronomical Photography of Precision."

After a consideration of the quantum theory, Prof. A. S. Eddington, in his fifth Gifford Lecture in the University of Edinburgh on Feb. 18, said it is now generally accepted that in the reconstruction of ideas required to remove the present discrepancy between classical and quantum laws, the quantum laws must form the basis. These grade into the classical laws when the quantum numbers are very large; and it is only then that the classical conception of the physical world—including space, time, electrons, force, etc.—has any application or meaning. In this reconstruction all the determinism is removed from the laws of physics; the apparent determinism is found to be merely high probability. The probability is high (amounting practically to certainty) when averages of large numbers are considered; but in individual processes only moderate odds are concerned. The new quantum mechanics contains only laws which decide the odds; it apparently has no cognisance of any factors deciding what actually will happen. In the old conflict between free will and predestination, it has hitherto seemed that physics comes down heavily on the side of predestination. The quantum theory has entirely removed this bias. Whatever view we may take of free will on philosophical grounds, we cannot appeal to physics against it. The latest picture of the atom contains no mark or factor to decide what *that* atom will do next (although it contains factors deciding the average conduct of a number of such atoms); and whilst further developments in the theory may possibly disclose such a mark, it is on the whole rather against the spirit of the modern conception to expect this.

In his sixth Gifford Lecture, delivered on Monday, Feb. 21, Prof. Eddington dealt with the nature of the stars. He pointed out that failure of the perfect gas laws begins when the atoms are so closely packed that they begin to jam against one another. Generally this begins when the density approaches that of the liquid state; but that refers to terrestrial atoms fully arrayed with their systems of electrons. In estimating the congestion at the very high temperature in the stellar 'ball-room,' we must remember that 'crinolines' of electrons are no longer worn. Thus the stellar ions will not begin to jam until a much higher density is reached, and stellar material can still be a true gas even when its density is that of water or of platinum. Evidently it is possible for stellar matter to reach a density transcending all terrestrial experience. This conclusion recalls a strange message contained in our observations of the faint 'Companion of Sirius,' which was previously dismissed as incredible. Apparently this star had a mass nearly equal to the sun's mass packed into a globe not very much larger than the earth. Fortunately it has been possible to test this conclusion by a method based on Einstein's theory of gravitation, and Prof. W. S. Adams, at the Mount Wilson Observatory, has confirmed this huge density. It is 60,000 times the density of water, and a ton of the material could be contained in a match-box. It is not a new chemical element; it is ordinary matter under extraordinary conditions, namely, with the atoms so shattered by high temperature that they can be packed into an extremely small compass.

A Lecture on "Conceptions of the Cosmos from the Times of Copernicus to Galileo" was delivered at Bedford College for Women (University of London) by Sir Frank W. Dyson, the Astronomer Royal, on Feb. 15. Before the sixteenth century the earth, moon, and sun were accepted as globes, the size and distance of the moon from the earth had been roughly calculated, but the theory of epicycles was still used to explain the movements of the stars in a geocentric cosmos. Copernicus (1473–1543), using Ptolemy's records, thought out a heliocentric system. His cosmos was a series of concentric circles, of which the fifth was the orbit of the earth, with the epicycle of its satellite, the moon. He added an unnecessary 'third movement' of the earth to account for its axis pointing always to the same region of the heavens. Tycho Brahe (1546–1601), though a careful observer, refused to accept the Copernican cosmos and imagined a heliocentric grouping of the planets, but a geocentric cosmos; the moon's and the sun's orbits turned about the earth as a centre, but the movements of the heliocentric planet group formed an epicycle. Kepler (1571–1630) rejected Tycho Brahe's theory and completed the Copernican system, founding his theories upon the incomparable observations of Tycho Brahe. He studied the orbit of Mars and established three laws, which include the principle that the orbits of the planets are not circles, but ellipses with the sun as a focus. His work was not immediately accepted. Galileo (1564–1642) developed the use of the telescope and thus discovered a larger number of stars and the nature of the surface of the moon. His main discovery was that of Jan. 7–14, 1610, when he observed the movements of the satellites of Jupiter and thus produced another argument in favour of the Copernican system. By the work of these four men the geocentric conception of Ptolemy was thus replaced by the heliocentric system now accepted.

Mr. F. J. W. Whipple, the Superintendent of Kew Observatory, sends us a description of a remarkable deposit of rime observed by him in Arundel Park and the neighbourhood on Saturday, Feb. 12. It will be remembered that the south of England was covered with fog for several days. The fog was exceptionally thick on the South Downs on Friday, Feb. 11. When Mr. Whipple made his observations on the Saturday morning it was misty. The rime in many places was heavy enough to bend the tree branches. In the light breeze the fragments of rime blown from the trees pelted the passer-by in no pleasant fashion. In places the fallen rime lay on the ground to the depth of an inch. Rime on the ground had not the brilliance of fresh snow: it made a rather dirty grey. From a distance the grey patches under the trees and bushes were more conspicuous than the unfallen rime. There was, of course, rime on the grass. The deposit on the wiry grass stalks was curious, however, in that very frequently it changed sides half-way up. The deposit on the lower half of the stalk pointed into the wind (the N.E. wind which prevailed when the rime was formed on the trees), but on the upper half the deposit was on the lee side. Another unusual phenomenon was the occurrence of pieces of ice embedded in an earth bank. Each of these pieces of ice was encrusted on a fragment of chalk. A chalk fragment about two inches square and half an inch thick might carry a lump of ice or rather a brittle crown of ice about an inch high. There was no ice on the soft earth or on the roadway nearby. The phenomenon occurred close to trees with a very liberal deposit of rime.

At the anniversary meeting of the Geological Society on Feb. 18, the awards already announced in our columns (Jan. 29, p. 169) were presented by the President, Dr. F. A. Bather. On behalf of Sir Albert Kitson, the Right Hon. W. Ormsby Gore received the Lyell Medal, and the balance of the Murchison Fund was handed to Sir Arthur Smith Woodward for transmission to Dr. Haughton. Alluding to a revival of interest in systematic concepts, in which palæontologists have played a large part, Dr. Bather then discussed the present position and possible future of "Biological Classification." Distinguishing the practical aim from the philosophical, the artificial system from the scientific, he showed the relation of the Key to the former and discussed the stages and various basic ideas of the latter. The phylogenetic mode of approach, and particularly palæontology, have made changes necessary. The phylogenetic method was contrasted with the morphological; the ways of breaking up a phylogenetic tree were discussed, and the concepts of the grade, the genus, the lineage, the gens, the seriation, and the species were expounded. Convergence and polyphyly affect genera and species no less than higher groups. The ordinary species (Linneon) is composed of elementary species (Jordanons); but the true *infima species* of a phylogenetic classification carried to its logical end would be the gene. If, then, a thoroughgoing phylogenetic system is impracticable, might it not be equally scientific to have an adaptational classification? Perhaps this would be more useful and more illuminating; but equally impracticable. Many of our present difficulties arise because the phylogenists have been hampered by a system built on a different plan. In Dr. Bather's opinion the only salvation lies in a compromise accepting the practical intention of binomial nomenclature, and producing a system sufficiently flexible for use by morphologist, ethologist, phylogenist, and stratigraphical geologist.

The Frazer Lecture in Anthropology for 1927 will be delivered at Cambridge on Mar. 2, the lecturer for this occasion being Dr. R. R. Marett. It will be remembered that this lecture is on a foundation formed a few years ago from a fund raised as a tribute to the work in anthropology of Sir James G. Frazer. It is delivered in rotation in the universities with which Sir James Frazer has been connected—Cambridge, Oxford, Liverpool, and Glasgow. Among those who have previously lectured on the foundation are the Rev. J. Roscoe, Dr. E. S. Hartland, and Dr. B. Malinowski. Sir James and Lady Frazer will entertain a number of friends to dinner in Trinity College on Mar. 1, most of whom will remain in Cambridge for the Frazer Lecture on the following day.

The well-known seismic district along the Dalmatian coast has lately been visited by violent earthquakes, the first and strongest at 4.19 A.M. on Feb. 14, and a second, also of destructive intensity, at about 2 P.M. on Feb. 16. Though the loss of life seems to have been small, the area of damage was of great size. Along the coast, it extends from Sebenico on the north to Trebinye on the south, towns which are about 150 miles apart; inland, it reaches beyond Mostar, which is about 40 miles from the coast. Several recent earthquakes in this district, such as the Sinj earthquake of July 2, 1898, have been traced to important dislocations; though, on the whole, the exact positions of the epicentres are not well known. The recent earthquake appears to have been connected with a long fault, roughly parallel to the coast, and possibly a short distance to the west.

Michael Faraday was born in Southwark, London, and his father's forge stood near the well-known "Elephant and Castle" of that place. The Southwark Borough Council desires to commemorate the association of this great pioneer of science with the borough by forming a special collection of standard and current literature on electrical and allied sciences in the Central Reference Library, and by placing in the library a bust of Faraday. It is proposed also to create a Faraday Memorial Library Fund, the income from which would be used to keep the library supplied with the best books upon these subjects. Both object and aim are worthy and appropriate, and we are glad to commend these to readers of Nature. Any contributions in support of this memorial in Faraday's native borough should be sent to the Town Hall, Walworth Road, London, S.E.17, and be addressed to the Mayor of Southwark.

An appeal of exceptional interest is issued by the Gravesend Borough Library and the Gravesend and District Scientific and Archæological Association with the object of raising funds towards the reconstruction of Milton Chantry for the purpose of a museum and library of local history. The Chantry, which is the oldest building in Gravesend and one of the most picturesque in the neighbourhood, dates, at latest, from the early fourteenth century, and is of the greatest importance to archæologists, and also, be it said, to the general public from the historical point of view. Much of the original timber of the roof remains. The walls of flint and chalk are mostly three feet thick and have been preserved by a casing of brick erected in Elizabethan or Jacobean times. The total amount required for reconstruction is £2500, of which £550 has already been contributed by the Office of Works and £500 by the Corporation of Gravesend. The latter body has also voted £400 per annum for upkeep in conjunction with the existing Borough Library. The scientific and educational value of a well-organised and well-arranged local museum needs no emphasis. But the importance of Gravesend as a centre of archæological and historical research, rich in prehistoric, early British, Roman, and Anglo-Saxon remains, already well represented in the collections in the custody of the Library Committee, render this appeal, which has the support of such bodies as the Society of Antiquaries, the Royal Anthropological Institute, and the Royal Historical Society, a matter of national and not merely of local interest.

The January issue of the *Quest* contains an interesting article by Prof. D. Fraser Harris on "Science and Preconceived Perfection," in which he gives numerous examples from the history of natural science and medicine of attempts to hinder the progress of science by religious doctrines or other preconceptions. One of the earliest examples of this was the opposition which Galileo encountered for his description of the spots on the sun, owing to the preconceived notion of his opponents that the sun was perfect. A similar preconceived idea of perfection led Hoffmann of Nuremberg to attack Harvey's discovery of the circulation, a constant return of blood to the heart being regarded by Hoffmann as an imperfect arrangement. Throughout the Middle Ages the progress of anatomy was checked by the Mohammedan injunction against dissection on the ground that touching a dead body rendered a man ceremonially unclean. The Italian surgeon Tagliacozzi, who introduced a plastic operation for repair of the nose, ears, and lips in the middle of the sixteenth century, was denounced for his impiety in daring to alter the human countenance, and after death his bones were scattered by order of the ecclesiastical authorities. In more modern times, the opposition to inoculation against small-pox, of which Voltaire was so ardent a propagandist, and later to vaccination and the use of chloroform in childbirth, was partly based on the belief that such methods were interfering with the will of Providence.

In continuation of the excellent series of exhibits dealing with modern scientific research which have recently been on view at the Science Museum, South Kensington, an exhibition has been arranged under the auspices of the British Research Association for the Woollen and Worsted Industries, which will be opened on Mar. 1 by the Earl of Balfour. Dr. F. A. E. Crew, Director of the Animal Breeding Research Department of the University of Edinburgh, is co-operating with the Association and has arranged a biological section designed to show the application of science to the wool industry in all its stages from the sheep to the finished fabric. In this section will be illustrated questions of breeding, feeding, and fleeces. The exhibits will be divided into groups showing research on wool characteristics and processes, technical research, dyes and wool, worsted spinning, woollen carding and spinning physical research. It should be noted that a number of the exhibits have been supplied by the firms connected with the Association. The Woollen Industries Research Association was incorporated in 1918 and has its own chemical, physical, and engineering laboratories at Torridon, Headingley, Leeds, with more than thirty trained investigators. Its annual budget is about £14,000. The fundamental work of the Association deals with pure research on wool and the processes involved, with the view of increasing the quality and quantity of the fibre, improving and cheapening manufacture, and enhancing the appearance and prolonging the life of the finished fabric.

At the invitation of the American Association of Economic Entomologists and the Entomological Society of America, the fourth International Congress of Entomology will be held at Ithaca, New York, presumably in the third week of August 1928. A preliminary programme will be issued in the near future.

At the annual general meeting of the Quekett Microscopical Club on Tuesday, Feb. 8, the following officers were elected: *President*, Dr. W. T. Calman; *Vice-Presidents*, Sir David Prain, Mr. D. J. Scourfield, Mr. J. M. Offord, Mr. C. D. Soar; *Hon. Treasurer*, Mr. F. J. Perks; *Hon. Secretary*, Mr. W. S. Warton; *Hon. Reporter*, Mr. A. Morley Jones; *Hon. Librarian*, Mr. C. S. Todd; *Hon. Curator*, Mr. C. J. Sidwell; *Hon. Editor*, Mr. W. S. Warton.

At the anniversary meeting of the Geological Society of London held on Feb. 18, the following officers were elected:—*President*, Dr. F. A. Bather; *Vice-Presidents*, Dr. J. W. Evans, Prof. E. J. Garwood, Dr. E. Greenly, Mr. H. W. Monckton; *Secretaries*, Mr. W. Campbell Smith and Dr. J. A. Douglas; *Foreign Secretary*, Prof. J. E. Marr; *Treasurer*, Mr. R. S. Herries; *New Members of Council*, Dr. E. E. L. Dixon, Dr. J. D. Falconer, Prof. V. C. Illing, Mr. Philip Lake, and Prof. H. H. Swinnerton.

At the annual general meeting of the Physical Society, held on Feb. 11, the following officers were elected:—*President*, Prof. O. W. Richardson; *Vice-Presidents other than Past Presidents*, Dr. E. H. Rayner, Prof. E. A. Owen, Dr. D. Owen, and Prof. F. L. Hopwood; *Secretaries*, Prof. A. O. Rankine, Imperial College of Science and Technology, and Mr. J. Guild, National Physical Laboratory, Teddington, Middlesex; *Foreign Secretary*, Sir Arthur Schuster; *Treasurer*, Mr. R. S. Whipple; *Librarian*, Mr. J. H. Brinkworth; *New Members of Council*, Mr. T. Smith, Prof. E. N. da C. Andrade, and Dr. Ezer Griffiths.

The Principal Trustees of the British Museum have appointed Dr. W. D. Lang, Assistant Keeper in the Department of Geology, to a Deputy Keepership in the same Department. Dr. Lang was educated at Christ's Hospital, Harrow School, and Pembroke College, Cambridge. He obtained a first class in Part I of the Natural Sciences Tripos in 1901 and his research work gained him the Sc.D. degree in 1919. He entered the service of the Trustees in 1902 as assistant in the Department of Geology. His chief publications have been on fossil Polyzoa, fossil corals, recent insects, philosophical biology, and the geology of the neighbourhood of Charmouth, Dorset.

The Dyers' Research Medal, offered each year by the Worshipful Company of Dyers for the best scientific research or technical investigation connected with the tinctorial arts which has been submitted to the Society of Dyers and Colourists for publication in its journal, has been awarded for 1925–1926 to Dr. H. H. Hodgson, for work carried out in the Department of Colour Chemistry at the Technical College, Huddersfield. Dr. Hodgson has had two papers in the Society's journal during this period: (1) "Behaviour of the Sulphides of Sodium in Aqueous and Alcoholic Media" (July 1925), and (2) "The Action of Sulphur on the Monochloroanilines" (Mar. 1926). During the year 1926, sixteen papers have been published in various scientific journals by Dr. Hodgson and his research students.

We are informed by Messrs. Carl Zeiss (London), Ltd., that a contract has just been signed for the purchase of a Zeiss planetarium for the city of Vienna. The opening date has been fixed for May.

The January number of *Watson's Microscope Record* (No. 10) contains a practical paper on "Critical Illumination," by Dr. F. J. Brislee; chapter 2 of "The Desmidiaceæ," by Mr. G. T. Harris; and a paper on "Relief Staining of Bacteria, Protozoa, Infusoria," by Dr. A. C. Coles, in which the use of a saturated aqueous solution of nigrosin is advocated as giving apparently permanent preparations showing minute characters and structure not otherwise seen. The *Record* is published three times a year, and will be forwarded free on application to Messrs. Watson and Sons, 313 High Holborn, W.C.1.

Applications are invited for the following appointments, on or before the dates mentioned:—A lecturer on public health at the Westminster Hospital School of Medicine—The Dean, Westminster Hospital Medical School, 12 Caxton Street, S.W.1 (Mar. 1). An assistant master at the Redhill Junior Technical School and Technical Institute to teach mathematics, with mechanics as a subsidiary subject—The Secretary, Education Committee, Municipal Buildings, Reigate (Mar. 2). A research bacteriologist at the Low Temperature Research Station, Cambridge—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1 (Mar. 11). A junior assistant at the Building Research Station, Garston, Watford—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1 (Mar. 11). An assistant lecturer in agriculture under the County of Southampton Education Committee—The Director of Education, The Castle, Winchester (Mar. 11). An assistant in the statistical department of the Rothamsted Experimental Station—The Secretary, Rothamsted Experimental Station, Harpenden (Mar. 17). An instructor in engineering science at the Kingston-upon-Thames Technical Institute—The Principal. A teacher of engineering subjects at a junior technical school of the Wandsworth Technical Institute—The Principal. A graduate for engineering subjects and mathematics at the Workington County Technical and Secondary School—The Principal. A senior laboratory assistant in the department of Pathology and Bacteriology of the University of Sheffield—The Professor of Pathology, The University, Sheffield. A part-time demonstrator of biology at St. Thomas's Hospital Medical School—The Medical Secretary, St. Thomas's Hospital Medical School, S.E.1. A junior physicist under the Linen Industry Research Association—The Secretary, Research Institute, Lambeg, Co. Antrim.

Our Astronomical Column.

A Fixed Easter.—Mr. J. J. Withers, University of Cambridge, has introduced a bill in the House of Commons proposing to fix Easter as the Sunday following the second Saturday in April, and thus reduce its possible range from five weeks to one week. The matter has been before a special committee of the League of Nations for the last year or two, on which there were representatives of the principal religious bodies, and it was agreed that no insuperable obstacle lies in the way, if there is sufficient consensus of public opinion in favour of the change. The subject was dealt with in an article in our issue of Nov. 27, 1926. It is likely that the present bill is intended merely to strengthen the hands of the League of Nations committee; if so, there is nothing to be said against it. But it would be undesirable to give it legal effect before obtaining general ecclesiastical sanction.

There are millions of people in Great Britain and Ireland who would not admit the power of a secular legislature to fix the date of a religious festival; the public holiday, of course, lies within its competence, but to divorce this from the feast with which it has always been associated would meet with serious opposition.

Spectroscopic Parallaxes.—Two papers on the spectroscopic parallaxes of stars are published in the current number of the *Astrophysical Journal* (vol. 64, No. 4). The first, by Adams, Joy, and Humason, gives the parallaxes of 410 M-type stars based on recent research into the behaviour of suitable lines in spectra of this type. The list includes all the Boss stars north of −30° declination, together with about 100 dwarf stars of faint visual magnitude; many stars classed as $K5$ at Harvard are also included. For the giant M-type stars the lines used were at λλ4207, 4258, 4389, 4489 (Fe); λ4077 (Sr$^+$); $H\gamma$, and $H\beta$. The reduction curves were based, primarily, on mean parallaxes from parallactic and peculiar motions; these results being corrected by a method of successive approximations. For the dwarf stars the lines found to be most suitable were λλ4318, 4435, 4454, 4586 (Ca); λ4535 (Ti blend); and λ4607 (Sr). The reduction curves were based entirely on trigonometric parallaxes. The results show an interval of more than six magnitudes between the faintest giants and the brightest dwarfs, within which there is an entire absence of stars. The rapid variation in luminosity with spectral type for the dwarf M-type stars also suggests the possibility of obtaining parallaxes from this relation alone.

The second paper, by A. V. Douglas, is on A-type stars. Two methods of attack were used. The first, depending on the variation in relative intensities of arc and spark lines, resembled that devised by Adams for later type spectra. The pairs of lines found by Douglas to show the necessary variations were: λλ4215 : 4227, 4233 : 4227, 4535 : 4481, and 4549 : 4481. In the second method a relation was discovered between luminosity and the width of the lines λ4481, $H\delta$, and $[K]$, so that seven criteria were finally available for determining parallaxes. The reduction curves were based on a combination of group with trigonometrical parallaxes, and were determined separately for stars of sharp- and diffuse spectral lines. The final results are given in a list of parallaxes of 200 A-type stars.

Research Items.

Malayo-Polynesians in America.—Dr. Paul Rivet again attacks the question of the migrations of Malayo-Polynesians to America in vol. 18, No. 5, of the *Journal de la Société des Américanistes de Paris*. He briefly reviews the evidence of physical anthropology and ethnography with which he has dealt previously. The form of certain types of skull in lower California shows a Melanesian affinity, while the Lagoa-Santa skull is of a type of wide distribution in South America and presents affinities with the hypsistenocephalic type of Melanesia and Australia. In the material culture a large number of objects of typical Polynesian or Melanesian character, of which a detailed list is given, are also found in America. The linguistic evidence—a detailed examination of grammatical structure and comparison of vocabularies—shows a close affinity between the Hoka family which extends, though not continuously, from Oregon to Salvador, and the Malayo-Polynesian family. If we accept Uhle's classification and dating of pre-Inca pottery in Peru, and put the first wave of immigration as contemporary with the proto-Nasca ware, this would give a date at about the beginning of our era, but Uhle's dates are too low and allow an inadequate period for the evolution of the stone age in America. These immigrants met and were to a great extent overwhelmed by the migrations of peoples from Asia who were responsible in the main for the general physical character of the American Indian; but it would be a mistake to regard the part played by the Malayo-Polynesian element in the racial make-up of America as negligible.

Individual Difference in Accident Rates.—The problem of accidents is still challenging attention. Some time ago a report by Miss E. M. Newbold was reviewed in this journal: in this report a statistical study of the human factor in the causation of accidents was made, and it appeared that, quite apart from the objective causes of accidents, there was a personal factor operating that rendered some people more liable than others to accidents. Since then the problem has been studied from another point of view by E. Farmer and E. G. Chambers, and their findings are published by the Industrial Fatigue Research Board in Report No. 38 (London: H.M.S.O. 2*s*. 6*d*. net). The writers tested workers in various occupations for æstheto-kinetic co-ordination, intelligence, and nervous instability. The results of these tests were correlated with the accident records of the same subjects. While the authors draw but tentative conclusions from a very interesting piece of work, yet, however tentatively expressed, the results are valuable. It appears that it can be definitely asserted that inequality in accident liability is not solely determined by external factors or by chance, but is due to measurable individual differences. A relationship can be shown to exist between accidents and poor æstheto-kinetic co-ordination, but there is no relationship between accidents and the higher intellectual processes. These results afford confirmation of the earlier work as well as adding fresh knowledge. It is perhaps not going too far to hope that the time will come when it will be possible to estimate an individual's accident liability with mathematical accuracy.

Ultramicroscopic Organisms as Symbionts.—In an article entitled "Ultramicroscopic Life," published in the Nov. issue of the *Rivista di Fisica, Matematica e Scienze Naturali* (Naples), Prof. Umberto Pierantoni gives an account of those ultramicroscopic organisms which are used by higher organisms as factors of their normal functions. These so-called ultramicrosymbionts occur at least as frequently as the microsymbionts, and the functioning of organs and tissues by means of such protoplasmic inclusions must be regarded as a normal phenomenon and not as analogous to pathogenic ultramicrobic symbiosis, which constitutes an abnormality of only a few individuals of a species. The penetration of ultramicrosymbionts into the egg of an insect may immediately determine a change in the direction of embryonal morphogenesis leading to the formation of new organs. Investigations on luminous animals have demonstrated that the presence of such ultramicro-organisms in many animals, especially cephalopods, is accompanied by the appearance of highly complicated structures — lenses, reflectors, refractors, analysers of light—due to stimuli exerted by them in the cells in which they become located. The effects which these organisms exert on the cell plasma undoubtedly tend to modify and regulate the activity, and indeed to determine the specific activity, of the plasma. Bioluminescence, with the many indisputable cases in which it is due to symbiosis, has entered a new field of study, and, if it could be proved that luminous ultramicrosymbionts exist, the phenomenon would admit of a definite explanation.

Life-History and Distribution of Limnæa.—Dr. C. L. Walton and W. Norman Jones (*Parasitology*, 18, No. 2, 1926) report the results of observations in North Wales on the life-history of *Limnæa truncatula*, the usual intermediate host of the liver-fluke of the sheep. The average number of eggs in 20 egg-masses of this snail, collected in March 1925, was 9·75, and the hatching period (in the laboratory) was 12–26 days, with an average of 20–21 days for the spring generation. The young snails were isolated and reared, and they deposited eggs during the first week of July, which hatched in the first week of August. *L. truncatula* is therefore self-fertile. Data were obtained which show that two and probably three generations occur between March and October. Dr. Walton and W. Rees Wright (*op. cit.*, No. 4, 1926) find that, in North Wales, *L. truncatula* occurs over a range of pH 6·0 to 8·6, *L. peregra* pH 5·8 to 8·8, and *L. palustris* pH 7·4 to 8·0 (three readings only), and they express the opinion that the hydrogen-ion concentration is not of vital importance to these snails or, on the evidence available, to mosquito larvæ. The differential distribution of *truncatula* and *peregra*—for these species are seldom found together though they may be abundant in contiguous environments and some overlapping may occur—is accounted for by the relatively broader foot and shell of *peregra*, which enables it to travel over the surface of soft mud in which *truncatula* would sink.

Forestry Research in South Africa.—The Research Station of the Forest Department of South Africa, situated at Deepwalls, Knysna, has made remarkable progress and carried out some important investigation work during the comparatively few years which have elapsed since its inauguration on up-to-date lines. One of the troublesome factors in connexion with forestry work in the Dominion is the restricted area and size of the indigenous forest. The department is seeking to rectify Nature's deficiencies in this respect by the artificial cultivation of conifers, with the view of the gradual reduction of imports of soft woods and the saving of expenditure in this direction. The opinion is held by a section of forest officers that in every country efforts should be made to safeguard the future of, and even extend when necessary, the indigenous forests; that a total reliance on forests of exotic species is, economically, a mistake. Those holding such views will be interested in the paper by Mr. John Phillips, of the Deepwalls Research Station (*Ecology*, vol. 7, No. 3, July 1926), dealing with the biology of the flowers, fruits, and young regeneration of *Olinia cymosa* Thunb. This is one of the South African forest trees and is known as 'hard pear.' The tree plays an important part in forest succession in the Knysna forest region, and also produces a most excellent timber for constructional purposes. Little has been known of the power of reproduction or facilities for propagation either of this or other important species of these curious indigenous forests. By his close study into the habits of *Olinia cymosa*, Mr. Phillips discloses an extraordinary state of affairs which, if equally true of other species, furnishes a reason for the poor condition of growth of the forests. In spite of an extravagant production of flowers and fruits season by season, by one individual or another, the production of fertile seeds is small, and only a very few natural seedlings actually result from a heavy crop of flowers. The problem of how to assist and increase the natural regeneration of the species is dealt with in some detail, as also the main factors, which require further elucidation.

Russian Exploration in Mongolia.—Expeditions of the Russian Academy of Sciences were working in Mongolia in 1925 and 1926, studying mainly soils, vegetation, and partly also the fauna of the country. The so-called Gobi 'Desert' has been crossed twice, and this enabled the expedition to state that the whole north-western part of Gobi does not represent a desert, but is a flat steppe, with brown soil with some pebbles, and populated by nomad Mongolians; there occur locally some low ridges and stationary sand-hills; underground waters are everywhere near the surface and the grass cover was generally good. In remarkable contrast with the present steppe landscape of the Central Gobi are groups of large trees (elms) which apparently mark some old valleys now filled in. A special party of the expedition was occupied in detailed studies of local soils, and special attention has been paid to the study of processes of origin and accumulation of soluble salts in the soils.

Volcanic Rocks of Central America.—In the *Journal of Geology* for Nov.-Dec. 1926, P. C. Putnam describes the petrography of the lavas of Central America. In an arcuate zone concave to the Pacific, vulcanism began in the late Cretaceous and Eocene, languished during the succeeding period when folding and intrusion were going on, and broke out afresh with explosive fury in the Miocene. The lava basements of the present volcanoes are thought to be of Pliocene age, while the cones themselves are of later age and have been built mainly of ejectamenta with only occasional lava-flows. Throughout this region half a dozen rock types are widely distributed, both in space and time, ranging from olivine-basalt through latite to rhyolitic pumice. Partial analyses show that all the types are simply related, the most characteristic feature of the province being the richness of the basalts in potash and the complementary abundance of soda at the rhyolite end of the series. This feature suggests that the basalts are not representatives of the layer which gives rise to plateau-basalts, but are rather differentiation products of an intermediate latite magma. The weighted silica percentage is 62, and that of other circum-Pacific provinces ranges from 58 to 63. The explosive phase of eruptivity that followed the Oligocene intrusions gives strong support to Dr. Day's recent recognition of the importance of the gases given off during the crystallisation of an underlying cauldron, and their bearing on local volcanic phenomena.

The *Elephas antiquus* of Pignataro.—A large fossil elephant's skull, found at a depth of 8 m. at Fontanarosa, on the southern slopes of the hills commanding Pignataro Interamna, near Cassino, is described by G. De Lorenzo, *Rivista di Fisica, Matematica e Scienze Naturali* (Dec.). The old quaternary soil in which the skull was found has previously yielded fossil mammoths, but the latest find is one of importance as it represents a complete skull of enormous dimensions, measuring 3·50 m. from the frontal protuberance to the apex of the tusk. Moreover, it appears to have been found in its original, and not in a secondary, position, the animal having sunk in muddy ground and been submerged by a further deposition of alluvium. Consequently it is hoped that the whole of the remainder of the skeleton may be found, although difficulties may be expected owing to the decalcification of the bones, possibly as a result of infiltration of water charged with carbon dioxide.

Oil in Burma.—An important contribution to the petroleum geology of Burma was made by Dr. L. Dudley Stamp at the meeting of the Institution of Petroleum Technologists on Jan. 11. Since the publication of Pascoe's well-known memoir on "The Oilfields of Burma" in 1912, very little information has appeared concerning work on oilfield developments, much remaining hidden in the archives of the companies responsible for the intensive geological surveys carried out for this purpose. Oil in Burma is not confined to the Peguan beds but, according to the author, may be found at all horizons from the middle of the Eocene to the top of the Peguan (Oligo-Miocene); such petroliferous horizons are definitely associated with intermediate conditions, *i.e.* phases in the history of the Burmese gulf when neither freshwater nor deep marine environments are implied; a clear understanding of the distribution of oil in the Tertiary rocks follows from a consideration of this gulf as the recipient of river-borne sediment from the north, and marine sediment from the south, and a good case is made out for proving the fallacy of one stratigraphical oil-bearing horizon in Burma. This stressing of essential *facies* rather than essential structure in oil accumulation constitutes a principle often overlooked in other countries than Burma; structure is necessary, but without the right type of rocks being involved, its testing makes an unprofitable and discouraging task. Evidence is adduced in support of the contention that mother- and reservoir-rocks in Burma are identical, *i.e.* that vertical migration is precluded by the rapid alternation of porous sand and impervious clay; lateral migration may have been operative. "Oil is always found in strata in which the majority of fossils are marine, but of shallow water type." This statement naturally leads the author to discuss the coal-oil relationship, which he is inclined to regard as accidental, rather urging that one essential to the formation of petroleum is a concentration of salts in the water of a land-locked lagoon or lake, or on the seaward side of a delta.

Low Temperature Carbonisation.—The Department of Scientific and Industrial Research has issued a report of a test of another process for the carbonisation of coal at low temperatures, in accordance with the scheme in vogue (Nature, Sept. 20, 1924, p. 441). This report of the Director of Fuel Research deals with the 'Freeman' Multiple Retort of British Oil and Fuel Conservation, Ltd., Willesden. In this plant the coal is fed into the top of a tower built up of circular compartments separately heated by external gas burners. The coal is mechanically stirred and moved downwards from one compartment to another until it leaves as a mixture of breeze and dust, which is therefore not directly available for use as domestic fuel but might serve for powdered fuel. The striking result was the high yield of tar, 21·1 gall./ton, which is the highest yet observed with any plant tested by the Fuel Research staff. This high yield may be due to the fact that the gas is removed immediately from the plant, each compartment having an offtake. The yield of gas was low, and of ammonia negligible. Considerable mechanical trouble occurred with the plant, and it may be inferred that the process is not technically mature.

The Thermal Ionisation of Elements.—In their earlier attempts to obtain experimental evidence of the thermal ionisation of elements, the experimental arrangements of Saha and his collaborators have always been open to the criticism that the ionisation potentials of the vaporised elements were less than the potential differences actually existing between various regions in the vapour. In their latest arrangement (*Zeit. fur Physik*, vol. 40, p. 648, 1926) Saha, Sur and Mazumdar have used a vacuum oven, similar to King's design, and have heated the elements under investigation in an auxiliary oven made of quartz. The latter was kept at a temperature lower than that of the vacuum oven, and served to regulate the vapour pressure of the elements. The degree of thermal ionisation was determined by measuring the electric current between two parallel graphite plates, which were mounted on molybdenum rods insulated from the oven, when a potential difference of only 1 volt was applied to them. The temperature of the vacuum oven was measured by a Wanner pyrometer, and that of the auxiliary oven by means of a thermocouple. With this arrangement no current was recorded when mercury, zinc, or cadmium were heated up to 2000° C.; heated magnesium gave only a small current, but heated potassium and sodium gave large currents of the order of some milli-amperes. These results are in complete agreement with the magnitude of the ionisation potentials of the elements investigated.

The Fluorescence of Iodine Vapour.—It is well known that iodine vapour may be caused to fluoresce by illumination with light of suitable wave-length, and that this fluorescence is markedly decreased by the addition of foreign gases to the vapour. G. Ramsauer (*Zeit. fur Physik*, vol. 40, p. 675, 1927) has recently made experiments to determine whether this decrease depends on the wave-length of the light which produces the fluorescence. Pure iodine vapour and iodine vapour containing air were simultaneously illuminated with light from the same source, and the intensities of the fluorescent light from the two samples of vapour were compared by means of a polarisation photometer. Within the limits of experimental error no difference was found when green or yellow light was used to produce the fluorescence. The vapours were also excited by light from an arc of which the anode consisted of an alloy of sodium and cadmium, and the lines of the fluorescent spectra produced by the cadmium and sodium lines respectively were photographed and compared. There was a faint indication that the molecules of air produced a slightly greater effect on the fluorescence caused by the sodium lines than on that caused by the cadmium lines. On the quantum theory it would be expected that the intensity of all the terms of a fluorescence series would be decreased in the same proportion when molecules of a foreign gas are added to the vapour. This was proved to be untrue in the case of measurements carried out on iodine vapour containing oxygen, when the cadmium, copper, mercury, and sodium lines were used to produce the fluorescence. It is suggested that the presence of molecules of a foreign gas causes a change in the probability of transition of the excited iodine molecules.

Micro-crystals in Electrolytically Deposited Silver.—An X-ray examination of the micro-crystals in electrolytically deposited silver, carried out by H. Hirata and H. Komatsubara, is described in the *Memoirs of the Kyoto College of Science*, Series A, Nov. 1926. The X-ray photographs show that the micro-crystals of silver have a tendency to deposit in a fibrous form, and that the diagonal axis of each cubic lattice is parallel to the axis of the fibre. These results contradict those of Glocker and Bozorth, who suggest that electrolytically deposited silver has no regular orientation.

Instruments for Measuring Alternating Currents.—An interesting paper, by Lieut.-Col. K. Edgcumbe and F. E. J. Ockenden, on recent improvements in the design of measuring instruments for alternating current work, was read to the Institution of Electrical Engineers on Feb. 3. Except for radio frequency measurements, the 'hot-wire' type of instrument, once so popular on the Continent, is now 'antiquated.' For measuring electric currents and moderate voltages, the 'moving-iron' type of instrument is coming into general use. For very high voltages electrostatic instruments are employed, and for measuring power, electrodynamic instruments. Practically every scale now used subtends an angle of 120° at the pivot instead of 90° as formerly. But this merely improves the ease with which they can be read. It has little effect on their accuracy. The range of electrostatic condensers can be multiplied to any extent by putting condensers in series with them. It is now also of importance to measure the peak value of the high voltage wave so as to be able to calculate the maximum value of the electric stress on the insulating material. The simplest method of doing this is by means of a neon tube. It is known that a neon tube, if exhausted to the point of minimum impedance, breaks down at a peak voltage which is practically independent of the frequency of the supply and the temperature. The neon tube, shunted by a variable condenser, is put in series with a high-pressure air-insulated electrostatic voltmeter. The 'striking' of the neon tube can be detected in the dark by the luminous effect produced, but it can always be detected by means of a head telephone in series with the neon tube. The accuracy of hot-wire ammeters at high frequencies is sometimes questioned as the 'skin effect' comes into operation. It is stated that the error due to this cause in a good instrument when measuring 3 amp. at a frequency of 5,000,000 does not exceed 1 per cent.

Preparation of Hydrogen Peroxide.—A simple method of preparing concentrated solutions of hydrogen peroxide is described by M. L. Kilpatrick, O. M. Reiff, and F. O. Rice in the *Journal of the American Chemical Society* for Dec. 1926. A 20 per cent. solution of sulphuric acid, cooled in ice, is treated with small quantities of sodium peroxide until nearly neutralised. The crystals of sodium sulphate which form on standing are filtered off, and the adhering hydrogen peroxide washed into the filtrate. Vacuum distillation at 60°-65° yields a 20 per cent. solution which is treated with silver sulphate to remove chloride. After further distillation the solution is concentrated at room temperature over sulphuric acid in a vacuum desiccator for three days. By this means an excellent yield of approximately 90 per cent. hydrogen peroxide is obtained.

The Royal Society Election.

SELECTED CANDIDATES.

THE president and council of the Royal Society have recommended the following candidates for election as fellows of the Society :—

E. V. APPLETON, M.A., D.Sc. Wheatstone Professor of Physics in the University of London. Formerly Fellow of St. John's College, Cambridge. Distinguished for his researches on electric waves, atmospherics, and the Heaviside layer. Author of many papers upon these subjects published in the *Proceedings of the Royal Society*.

T. G. BROWN, M.D. Professor of Physiology, University College, Cardiff. Distinguished for his knowledge of physiology. Author of "Studies in the Physiology of the Nervous System" (*Quart. Jour. Exper. Physiol.*, 1909–1916), and many other papers.

R. H. BURNE, M.A. (Oxon). Curator of the Department of Comparative Anatomy, Museum of the Royal College of Surgeons. Author of many important contributions to comparative anatomy extending from 1892 until 1923, and published in the *Proceedings of the Zoological Society*, *Proceedings of the London Malacological Society*, the *Journal of the Linnean Society*, and *Journal of Anatomy and Physiology*.

J. CHADWICK, Ph.D. Fellow of Gonville and Caius College, Cambridge, and Assistant Director of Radio-Active Research in the Cavendish Laboratory. Distinguished for his researches on radio-activity and atomic structure, especially investigations on the properties of α- and β-particles and on the magnitude of the charge on the nucleus and the law of force around it. Since 1919 he has collaborated with Sir Ernest Rutherford in pioneer investigations of the disintegration of elements by α-particles which have yielded results of fundamental importance.

G. M. B. DOBSON, M.A. (Cantab. and Oxon), D.Sc. (Oxon). University Lecturer in Meteorology, Oxford. Distinguished for his work in meteorological physics. As Major in the R.F.C. was in charge of instrument research for the Air Force at Farnborough and at the Air Ministry, and designed many aircraft instruments now in use. Author of papers in the *Proc. Roy. Soc.* and other journals on conditions in the upper atmosphere, atmospheric turbulence and similar topics.

S. Z. DE FERRANTI, Hon. D.Sc. (Manch.). Electrical Engineer. Faraday Medallist of the Institution of Electrical Engineers. He has contributed in a notable degree to the advancement of electrical engineering, especially by his remarkable pioneering work in relation to the generation and distribution of energy by means of electric current at high voltages. His work on the electric furnace, on the electric energy meter, and in improving alternating current generators and motors, has been of the greatest value.

J. KENDALL, M.A. (Edin.), D.Sc. (Edin.). Professor of Chemistry, Columbia University, New York. Distinguished as an investigator in physical and general chemistry. Has published since 1912, partly with collaborators, more than sixty papers in *Proc. Roy. Soc.*, *Jour. Chem. Soc.*, *Phil. Mag.*, *Jour. Amer. Chem. Soc.*, *Jour. Phys. Chem.*, etc., dealing with the ionisation process, strong electrolytes, correlation of ionisation and solubility in solution, and related subjects.

P. P. LAIDLAW. Investigator at the National Institute for Medical Research, Hampstead. Formerly Dunn Professor of Pathology, Guy's Hospital. Distinguished as a pathologist, pharmacologist, and biochemist.

A. A. LAWSON, D.Sc., M.Sc., Ph.D. Professor of Botany, University of Sydney. Investigator of embryology of Gymnosperms (*Annals of Botany*, 1904–10, and later in Australian publications), seven memoirs; of Gametophytes of Psilotaceæ (*Trans. Roy. Soc. Edin.*, 1915–16); also of cytology (*Trans. Roy. Soc. Edin.*, vols. 47-48); an authority on algal floras of the west coast of America, Jamaica, and Britain.

J. W. MELLOR, D.Sc. Inorganic, physical and technical chemist. Director of the British Refractories Association and Principal of the Pottery School, Stoke-on-Trent; Honorary Secretary of the Ceramic Society. Distinguished as the author of "A Comprehensive Treatise on Inorganic and Theoretical Chemistry," ultimately extending to at least twelve volumes, of which six are now published—a reference work so valuable to chemists that its importance can scarcely be over-estimated. Is the leading authority on the scientific principles underlying the pottery industry, and the author of some fifty original publications on the chemistry and physics of ceramics.

OTTO ROSENHEIM. Distinguished for his investigation into the chemical nature of substances of physiological importance. His work on sphingomyelin and the galactosides of the brain is recognised to be definitive. He discovered, simultaneously with others but independently, the effect of irradiation upon cholesterol. With Dudley he has established the chemical nature of spermine and effected its synthesis.

M. SAHA, D.Sc. Professor of Physics, University of Allahabad. Especially distinguished for his development of the theory of high-temperature ionisation, which has been applied by himself and others to account for many of the principal features of solar and stellar spectra.

J. S. B. STOPFORD, M.D. Professor of Anatomy, University of Manchester. Distinguished for his investigations on the peripheral sensory nervous mechanisms, and particularly for the correlation of the results of his anatomical, experimental, and clinical observations, the one with the other, as well as with those of other workers (*Jour. Anat.*, 1918–21; *Lancet*, 1915–22; *Brain*, 1920); and for his technical achievement in determining the exact distribution of arteries in the brain, and enunciating important morphological principles and clinical applications (*Jour. Anat.*, 1916 and 1917).

H. H. THOMAS, Sc.D. (Camb.). Petrographer to H.M. Geological Survey. Harkness Scholar and Sedgwick Prizeman. Distinguished for his researches in petrology and stratigraphical geology. Author of many papers in the Geological Society publications dealing with the stratigraphy, palæontology, and petrology of South Wales, petrology of the sapphire bearing rocks of Mull and of the Triassic sediments of Devonshire; also papers on minerals and technology in the *Mineralogical Magazine*.

C. M. WENYON, M.B. B.S., B.Sc. (Lond.). Director of Research in the Tropics to the Wellcome Bureau of Scientific Research. Distinguished for his work in medical protozoology. Author of more than fifty published memoirs embodying the results of his researches on the parasitic Protozoa—especially those causing diseases in man. He has made important contributions to protozoology, and to knowledge of leishmaniasis, malaria, amœbic dysentery, and trypanosomiasis.

Birds of Ecuador.[1]

THIS is a companion volume to the "Distribution of Bird-Life in Colombia," forming vol. 36, 1917, of the *Bulletin of the American Museum*. It differs from many other valuable ornithological books in the fact that at least one-third of it is most interesting reading, and not for specialists in ornithology alone. The introductory chapters, after giving a review of the history of Ecuadorean ornithology, and describing the work done in Ecuador by the American Museum's expeditions, partially under the leadership of the author himself, describes clearly and vividly the general physiography of the country, the distribution of forests, the climatic conditions, and chiefly the life-zones. The author admits four life-zones: the tropical, the subtropical, the temperate, and the Paramo zone, which is the treeless region above 11,000 feet to the snow line.

While the avifauna of the subtropical zone must have derived from the tropical, and that of the temperate from the subtropical one, that of the Paramo, the youngest Andean zone, has acquired its bird-life comparatively recently, not from the neighbouring temperate zone of the Ecuadorean Andes, but very largely from its sea-level equivalent in Patagonia. This is fully explained by numerous examples. In comparing the various regions, numbers of genera are often used; this is not very useful, however, as the limits of genera are so differently defined by various ornithologists, the number of genera generally being greater in American works than in European, with one or two exceptions. It would be better if comparative lists of faunal regions were only given in species and subspecies.

Both books of Dr. Chapman show how wonderfully rich in species the highlands of the Andes are, in comparison with, for example, the elevated portions of Africa; thus, while on Ruwenzori only 95 'zonal' birds, as the author calls them, are known, not less than 412 are recorded from Ecuador, of which about 300 could be found within an area no larger than that occupied by Mt. Ruwenzori. This is doubtless due to the much larger extent of the highlands of the Andes as well as to their much greater height, but also, one may add, to the fact that altogether South America—even the lowlands—is richer in species than Africa. 1508 species and subspecies are included in the list of the birds of Ecuador, a larger number than has before been recorded from an area of similar size. Only 151 forms are treated trinomially as subspecies. The reason for this is that a number of forms have been admitted as species, because it is not known that they intergrade with others. This is still often done in America, but the known existence of intergradations is due to the material available in collections, and it is impossible to say if intergradations occur in the case of rarer birds, of which only a few skins are known. The method of many modern European ornithologists, who regard as subspecies all forms agreeing in the essential characters and only differing in shades of colour, size, or other details, if they strictly represent each other geographically, seems to be more natural.

Dr. Chapman is to be congratulated on his book, which is adorned by maps, photographs of scenery, and by excellent coloured plates of birds, and it is to be hoped that a volume on the birds of Peru may follow before long, so as to give us a still fuller knowledge of the birds of western South America.

University and Educational Intelligence.

CAMBRIDGE.—The following have been appointed as the Council of the School of the Physical Sciences: Mr. A. Berry, Mr. Cameron, Prof. Eddington, Mr. R. H. Fowler, Prof. Hutchinson, Prof. Inglis, Dr. H. Jeffreys, Mr. Landon, Sir Joseph Larmor, Mr. Lees, Mr. McCombie, Prof. Newall, Sir William Pope, Sir Ernest Rutherford, Prof. G. I. Taylor, Mr. L. B. Turner.

Dr. A. C. Haddon has been elected a member of the governing body of the International Institute of African Languages and Cultures. Dr. R. R. Marrett will give the Frazer lecture on Mar. 2 on the subject, "The Diffusion of Culture."

The General Board of Studies has recommended to the University that the readership in geography, about to become vacant by the resignation of Mr. Lake, should be continued.

Honorary degrees are proposed for Brigadier-General E. W. Costello, V.C., officer in command of the University contingent of the Officers' Training Corps, and for Colonel T. C. Hodson, reader in ethnology.

Three Davison scholars will be elected next term for a year's study at Harvard, Yale, and Princeton Universities. Scholars are chosen from undergraduates or bachelors of arts in residence.

THE *Faraday House Journal* for the Lent term shows that there are 83 students in their first year in the college, 51 in their second year, which is spent in mechanical engineering works, 74 in their third year, spent in college, and 71 in their fourth year, spent in electrical engineering works. The names of 45 old students who have obtained appointments since the issue of the Michaelmas number of the journal are given, with the titles of the posts obtained. There are five short scientific articles by staff and old students, amongst them one by the Principal, Dr. A. Russell, showing that the recent experiments which appear to indicate that an electric spark can pass between electrodes near together when the difference of potential between them is less than 350 volts, are probably vitiated by the electrostatic attraction between the electrodes having pulled them together. There are several scholarships and exhibitions offered by the college to be competed for in April next.

THE prefatory note to a pamphlet published by the Universities Bureau of the British Empire (50 Russell Square, London, W.C.1), entitled "Professional Schools, Post-Graduation Courses, Specialist Studies, in the Universities and University Colleges of Great Britain and Ireland, 1926–27," clearly describes its purpose: "Of their [the universities] several fields of study the greater part is common ground, yet each of them has its special plots which it cultivates. . . . The statements which follow indicate the respects in which the universities, individually, specialise, *i.e.* undertake work which is not common to them all." That the pamphlet accomplishes what it promises can best be shown if it be imagined that half-a-dozen students, unacquainted with the "special plots" of universities, desired, respectively, to attend lectures in oceanography, constitutional experiments in the Irish Free State, problems of bi-lingualism, tuberculous diseases, technical chemistry, the leather industry. Twenty minutes' study of this pamphlet would save them hours of hunting through bulky prospectuses and calendars, and would save much preliminary correspondence with registrars.

Calendar of Discovery and Invention.

February 27, 1706.—On this day John Evelyn, the diarist, died. He is commemorated here for his "Silva, a discourse of forest trees," 1664. It was Evelyn's house, Saye Court, Deptford, in which lived Peter the Great. Evelyn is also known as one of the founders of the Royal Society.

February 27, 1812.—Wilhelm von Biela, an Austrian major, on Feb. 27, 1812, discovered Biela, the comet to which his name was given. The comet had a period of 6¾ years, and when it returned in 1846 and 1852 it was seen to have divided into two comets. It then disappeared, but at the end of 1872 showers of shooting stars were observed, and it is believed these were caused by the breaking up of the comet.

February 28, 1838.—A report on Kew Gardens by Dr. John Lindley and two practical gardeners, dated Feb. 28, 1838, recommended that the gardens should be transferred to the care of the nation. They were duly taken over by the Commissioner of Woods on April 1, 1840, and W. J. Hooker was appointed director. It was under his skilful management that the gardens gained the high reputation they now enjoy.

March 1, 1866.—While a journalist in London, Walter Weldon (1832–1885) became interested in industrial chemistry, and though at first ignorant of chemical analysis, on Mar. 1, 1866, he took out the first of several patents connected with the manufacture of soda and chlorine. His introduction of the 'lime-manganese' process in the production of chlorine reduced the price of bleaching powder £6 a ton and, in the words of Dumas, cheapened "every sheet of paper and every yard of calico." The Weldon process has now been superseded by electrolytic methods.

March 2, 1617.—This is the date of the first British patent, but it was the Act of 1623 which for the first time secured "the sole working or making of any manner of new manufactures within this realm to the true and first inventor."

March 4, 1866.—On the memorial to Sir Norman Lockyer in the observatory on Salcombe Hill, Sidmouth, he is described as a "pioneer in the investigation and interpretation of the chemistry of the sun and stars and in the science of astronomical physics." It was on Mar. 4, 1866, that Lockyer first applied the spectroscope to the direct examination of the sun's surface, and in the same year he proposed a new method of observing the 'red flames' of the sun in daylight. A more powerful instrument came into his hands in October 1868, and on Oct. 20 he wrote to the Royal Society: "I have this morning perfectly succeeded in obtaining and observing part of the spectrum of a solar prominence." Janssen had achieved the same result in India, and the joint discovery was recognised by the striking of a medal by the French Government.

March 5, 1874.—Dr. (now Sir) David Ferrier brought before the Royal Society his experiments mapping the surface of the brain of the monkey into regions whence minute electrical stimulation was found by him to evoke precise movements of the face and limbs, characteristic for each region. The experiments were made to test "the theory of Hughlings Jackson that unilateral epilepsies are caused by irritation of the grey matter of the cerebral hemisphere." Ferrier's experiments laid the foundation of the knowledge which guides the physician and surgeon in locating to-day the seat of injury, tumour, etc., in the cerebrum. Moreover, the success of the surgical operations on the monkey's brain obtained in those experiments made clear that similar success might be attained on the brain of man; and in 1884 Rickman Godlee removed a tumour from the human brain. E. C. S.

Societies and Academies.

LONDON.

Royal Society, Feb. 17.—**G. C. Simpson**: The mechanism of a thunderstorm. The theory that the separation of electricity is brought about by the breaking of raindrops is adopted. The orders of magnitude of the meteorological and electrical quantities involved are in accordance with observations. The observations made by Schonland and Craib in South Africa of changes of electrical field-strength produced by lightning discharges are in complete accord with the theory.

G. U. Yule: Wolfer's sunspot numbers considered as a disturbed periodic series. The series of sunspot numbers is analogous to the data that would be given by the observed departures of a simple pendulum subjected to random (or largely random) impulses. The graph of such a series is very smooth, but amplitude and phase are continually changing, just as with the sunspot graph. The problem of determining period and 'disturbances' for such a series is attacked by two methods: (1) By forming the least-square equation of the form appropriate to a simple harmonic function

$$u_x = ku_{x-1} - u_{x-2},$$

between three consecutive terms. Trial of the corresponding extended equation appropriate to two periods gave no evidence of the existence of any period other than the fundamental. (2) By forming the general least-square linear equation

$$u_x = b_1 u_{x-1} - b_2 u_{x-2},$$

and solving as a finite difference equation: the solution is a heavily damped harmonic function. The correlations between u_x and the preceding terms up to u_{x-5} again fails to give evidence of any period other than the fundamental. The 'disturbances' (divergences of u_x from the value estimated by the two preceding terms) show two conspicuous characteristics: (*a*) a tendency to be mainly positive and highly variable, mainly negative and much less variable, over alternate intervals of 40 to 42 years; (*b*) a tendency to be mainly positive during the rise of the graph, mainly negative during the fall.

H. Horrocks: Meteorological perturbations of tides and currents in an unlimited channel rotating with the earth. As tidal predictions from analysis of observations still differ considerably from observations, this paper aims at throwing light on the type of disturbance to be expected when conditions of wind and atmospheric pressure vary at the ocean surface. The special basin considered is an unlimited rotating channel with atmospheric conditions varying across it, and turbulence in the water is taken into account.

G. M. B. Dobson, D. N. Harrison, and J. Lawrence: Measurements of ozone in the earth's atmosphere and its relation to other geophysical conditions (Part 2). As previously found, there is a marked connexion between the amount of ozone and the meteorological upper-air conditions. Possible reasons for this connexion are briefly discussed and connexions with terrestrial magnetism and possibly with sunspots are indicated.

M. Bentivoglio: An investigation of the rate of growth of crystals in different directions. The crystal is grown in a rotating vessel, and relative rates of face-growth are determined for crystals of isomorphous double sulphates of magnesium-ammonium, iron-ammonium, and magnesium-potassium, and potassium and ammonium tartrates. The measurements show that, under conditions of experiments, (i) similar faces of a *simple* form grow at same rate, even when of different sizes. Hence a misshapen crystal, if grown under uniform conditions, *tends* towards the ideal form. (ii) On a combination, unlike faces grow at different rates, like faces grow at the same rate, except when adjacent to a large face of another fast-growing form. Except in this case there is a constant ratio between rates of growth of any two different forms. (iii) In crystals having no centre of symmetry, rates of growth of parallel faces may be widely different. (iv) In isomorphous series the order of increasing rates of growth is not the same in different members.

P. A. M. Dirac: The quantum theory of the emission and absorption of radiation. The problem is treated of an assembly of similar systems satisfying the Einstein-Bose statistical mechanics, which interact with another different system, a Hamiltonian function being obtained to describe the motion. The theory is applied to the interaction of an assembly of light-quanta with an ordinary atom, and gives Einstein's laws for the emission and absorption of radiation. The interaction of an atom with electromagnetic waves is then considered, and it is shown that if one takes the energies and phases of the waves to be q-numbers satisfying the proper quantum conditions instead of c-numbers, the Hamiltonian function takes the same form as in the light-quantum treatment. The theory leads to the correct expressions for Einstein's A's and B's.

Physical Society, Dec. 10.—**A. O. Rankine** and **J. W. Avery**: Electrical polarisation in selenium cells and the effects of desiccation. The secondary E.M.F.'s displayed by selenium cells and the apparently abnormal effect of illumination on the corresponding secondary currents were measured. Both are probably due to an invisible water film in parallel with the selenium. That this film is the principal seat of the polarisation seems to be proved by the fact that the polarisation disappears almost completely with prolonged drying. On this basis a satisfactory quantitative explanation of the various effects is given. An important practical consequence of the desiccation of the cell is the large increase obtained in its sensitivity to light.—**T. G. Hodgkinson**: Synchronous alternating-current motors and mechanical vibrating systems maintained by thermionic valves at the frequency of the vibrating systems. The design of a chronograph which will give a time trace subdivided into units and fractional units requires the association of a rotating system and a vibrating or time-keeping system. If a low-frequency vibrating system be employed, the rotating system, although keeping good average time, may show exaggerated errors in unit subdivisions due to acceleration and deceleration between periods of control. The paper discusses the association of a high-frequency synchronous alternating-current motor with a high-frequency valve-maintained tuning-fork.—**K. R. Rao**: (1) On the spectrum of ionised tin; (2) On the spectrum of doubly ionised gallium and indium.

LEEDS.

Philosophical and Literary Society, Jan. 25.—**J. Lamb**: A 15-ic resolvent of the sextic equation. If this resolvent—whose coefficients are all invariants—has a rational root, the sextic breaks up into three quadratic factors involving a cubic irrationality.—**H. Jones** and **R. Whiddington**: The passage of electrons through gases. Quantum energy losses appear to occur when low-speed electrons pass through gases at low pressure. These losses in some cases correspond with sufficient accuracy with previously known critical potentials, but in other cases do not so correspond.—**W. R. Atkin**: Development of the Sorensen equation for the isoelectric points of ampholytes. The isoelectric point of a simple ampholyte such as an amino acid is $h=\sqrt{k_w . k_a/k_b}$, but this equation is not valid for proteins where the terminal $-NH_2$ and $-COOH$ groups are not necessarily equal in number. The isoelectric point of proteins is given by the equation $h^2+k_a(1-n)h-n . k_w . k_a/k_b=0$, where n is the ratio of $-COOH$ groups to $-NH_2$ groups, and k_a and k_b represent average values of the acidic and basic dissociation constants.

WASHINGTON, D.C.

National Academy of Sciences (*Proc.*, Vol. 12, No. 12, Dec.).—**Arthur Bramley**: Maxwell's equations and atomic dynamics. Electric and magnetic forces within a charge are stated as functions of the velocities of the moving body and its position. This satisfies the first of Maxwell's equations and gives the second set as equations of motion of the charge; from the latter, Bohr's frequency condition can be derived.—**Lucien B. Taylor**: The spectrum of krypton in the extreme ultra-violet.—**C. H. Kunsman**: Some thermionic experiments with a new source of positive ions. Fused mixtures of iron oxide with about 1 per cent. of an oxide of an alkali or alkaline earth metal form a satisfactory hot anode in a vacuum tube. The positive ions emitted are single atoms, mostly of the added metal, stripped of one electron. Positive ions are emitted when the equivalent voltage of the work function for vaporisation of the ion is greater than the potential holding the outer electron to the atom.—**J. H. Van Vleck**: The dielectric constant and diamagnetism of hydrogen and helium in the new quantum mechanics. Whenever the quantum numbers are small, the theory developed here gives values more in accord with experiment than those of the old quantum theory.—**Richard C. Tolman**: On the equilibrium between radiation and matter. From the first and second laws of thermodynamics, an equation connecting concentration and temperature can be obtained. It contains a constant b, requiring a knowledge of the absolute entropy of the system; Planck's procedure, $S=k \log P$, where S is the absolute entropy and P is the total number of stationary states the energy of which does not exceed the total energy available, may lead to the evaluation of the constant b.—**R. C. Gibbs** and **H. E. White**: Extension of doublet laws in the first long period to chromium and manganese.—**Leonard B. Loeb**: Ionic mobilities in ammonia-hydrogen mixtures and an anomalous effect of ammonia. Traces of ammonia in hydrogen and in air increase the mobility of the positive ions by as much as 30 per cent. without affecting the negative ion, and the formation of a stable NH_4^+ ion which prevents clustering is suggested. 0·1 per cent. and more of ammonia decreases both ionic mobilities by about the same amount. Experiments to find if ammonia would 'protect' the positive ion from ether suggest that the ether molecule attaches to the positive ion in preference to the ammonia molecule.—**Carl Eckart**: Note on the correspondence principle in the new quantum theory. If the co-ordinate matrix is expanded in terms of Planck's constant, the first term approaches the coefficient of the $(m-n)$th harmonic in the Fourier expansion of the motion in the old theory when n approaches infinity. For large quantum numbers, the Fourier coefficients thus constitute a first approximation to the matrix terms, in accordance with the correspondence principle.—**M. Demerec**: Miniature-a—a second frequently mutating character in *Drosophila virilis*. This wing character 'mutates' to wild type at any stage in the life-history; it is sex-linked.—**Chas. W. Metz**: Genetic evidence of a selective segregation of chromosomes in Sciara (Diptera). Maternal chromosomes separate from the paternal ones, the maternal group always going to the pole to remain in the spermatocyte.—**Roscoe G. Dickinson** and **Allan C. G. Mitchell**: Decomposition of ammonia by optically excited mercury atoms. The photochemical decomposition is sensitised by mercury vapour illuminated by a cooled quartz mercury arc with radiations of less than 2340 Å.U. filtered off. Diffuse band fluorescence in the green and ultra-violet accompanies the action.—**J. M. Cork, C. James**, and **H. C. Fogg**: The concentration and identification of the element of atomic number 61. *L*-series lines of the new element were given by a neodymium concentrate obtained from a large quantity of Brazilian monazite sand.—**Gregory Paul Baxter** and **Howard Warner Starkweather**: (1) The density of oxygen and its compressibility below one atmosphere (ii). The average corrected normal density is 1·42897, the coefficient of deviation from Boyle's Law −0·00092 per atmosphere, and the molal volume 22·4144 litres. The atomic weight of helium (density 0·17846) is 4·0001, the last decimal place being without special significance. (2) The density, compressibility, and atomic weight of nitrogen. The average density at 1 atmosphere is 1·25036. The average of the coefficient of deviation from Boyle's Law between 0 and 1 atmosphere is −0·00045 and the average atomic weight 14·006(7).—**William D. Harkins** and **Hugh A. Shadduck**: The synthesis and disintegration of atoms as revealed by photography of Wilson cloud tracks (see NATURE, Dec. 18, 1926, p. 875).—**Hugh Stott Taylor** and **John Reginald Bates**: Photosensitised decompositions by excited mercury atoms. Various gases, with and without mercury vapour, were passed through a system including a cooled mercury arc; the difference in the rate of increase of pressure in each pair of experiments indicated the occurrence of decomposition. Water gives oxygen and hydrogen in excess, ethyl alcohol gives acetaldehyde and other decomposition products, benzene gives some diphenyl, and so on. Ammonia gives a big excess of hydrogen, suggesting decomposition by stages, probably through hydrazine.—**Cecilia H. Payne**: (1) Some applications of the ionisation formula. Graphical illustration of the principles of the comparison of the state of ionisation of the atmospheres of stars for which both temperature and pressure differ. Curves for pressure change at constant temperature give the ratio in partial electron pressure in the atmospheres of two stars of known temperature, if the intensity ratio of the corresponding spectrum line is known. (2) On the spectra of stars of class *cF*8.—**Willard J. Fisher**: The apparition dates of the Andromede (or Bielid) meteor swarms. The method used by H. A. Newton is applied to the known records of this shower. Apparitions may be expected yearly about Nov. 16-19. Three of the 'plots' converge at Nov. 16·7, 1935 U.T.—**Maynard M. Metcalf**: Larval stages in a protozoon. The Opalinidæ, which are commensals in the recta of frogs and toads, are arranged in an evolutionary table ranging from Protoopalina, an archaic genus of the Triassic, cylindrical in form and with two nuclei, through a flattened form, through another cylindrical form with four or more nuclei, to the flat Opalina, which may be broad or narrow. Opalinids from tadpoles showing all these varied stages in development have been found.—**S. Lefschetz**: Transformations of manifolds with a boundary.—**Paul Slavenas**: A possible way to discuss the fundamental principles of relativity. The method is applied to the motion of a rigid system relative to another in Euclidean space, and it is found that Euclidean space admits the law of uniform translation, and that the moving system undergoes contraction in the direction of motion.—**R. L. Moore**: Concerning paths that do not separate a given continuous curve. In space of two dimensions, every two points that do not belong to a given continuous curve may be joined by a simple continuous arc that does not disconnect that curve.—**W. A. Manning**: On simply transitive primitive groups.—**L. E. Dickson**: Quadratic forms which represent all integers.—**Luther Pfahler Eisenhart**: Congruences of parallelism of a field of vectors.—**Gordon T. Whyburn**: Concerning certain types of continuous curves.—**H. S. Vandiver**: Summary of results and proofs concerning Fernat's last theorem (second note).

Diary of Societies.

SATURDAY, FEBRUARY 26.

BRITISH PSYCHOLOGICAL SOCIETY (Industrial Section) (at Royal Anthropological Institute), at 11 A.M.—Dr. C. Delisle Burns: The Group Mind in Industry.

MERSEYSIDE AQUARIUM SOCIETY (at Liverpool University), at 3.—Prof. J. Johnstone: Address.

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS (Associates' and Students' Section) (at Neville Hall, Newcastle-upon-Tyne), at 3.—W. Leebetter: Winning Thin Seams of Great Britain.—Papers open for further discussion:—Screening and Washing Plant at Deaf Hill Colliery, by L. F. H. Booth; Steam and Electric Locomotives for Colliery Purposes, by P. F. Hope.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr. J. B. McEwen: Beethoven (1).

MONDAY, February 28.

Society of Chemical Industry (Joint meeting of Fuel and Yorkshire Sections) (at Queen's Hotel, Leeds), at 2.30.—The Influence of Atmosphere and Temperature upon the Scaling of Steel:—Dr. C. B. Marson and Prof. J. W. Cobb: Part I. Scaling by Air, Water Vapour, and Carbon-Dioxide.—Dr. H. T. Angus and Prof. J. W. Cobb: Part II. Prevention of Scaling by Hydrogen and Carbon-Monoxide.—Dr. A. Parker: A Thermal Study of the Process of Manufacture of Water Gas.—At 5.—R. A. Mott: A Study of Coke Formation.—H. Hollings: Coke in Relation to some of its Industrial and Domestic Uses.—Margaret F. Bligh and H. J. Hodsman: The Behaviour of Cokes in the Open Grate.

Royal Irish Academy, at 4.15.

Cambridge Philosophical Society (in Botany School, Cambridge), at 4.30.—R. E. Holttum: Some Problems of Plant Biology in Malaya.—*Papers to be communicated by title only*:—Dr. A. S. Parkes: The Mammalian Sex-Ratio.—Dr. V. Nath: On the Present Position of the Mitochondria and the Golgi Apparatus.—H. E. Tunnicliffe: Glutathione.—G. C. Steward: On Herschel's Condition and the Optical Cosine Law.

Institute of Actuaries, at 5.—E. W. Phillips: The Actuary in Commerce and Industry.

Royal College of Surgeons of England, at 5.—Prof. V. Z. Cope: Shock and Collapse, with special reference to Acute Abdominal Disease.

Institution of Electrical Engineers (North-Eastern Centre) (at Armstrong College, Newcastle-upon-Tyne), at 7.—Lt.-Col. K. Edgcumbe and F. E. J. Ockenden: Some Recent Advances in Alternating-Current Measuring Instruments.

Institution of Electrical Engineers (Tees-Side Sub-Centre) (at Cleveland Technical Institute, Middlesbrough), at 7.—J. R. Beard and T. G. N. Haldane: The Design of City Distribution Systems, and the Problem of Standardisation.

Royal Institute of British Architects, at 8.—H. Corbett: Organisation and Cost of the Building Industry in America.

Royal Society of Arts, at 8.—Prof. E. G. Coker: Photo-elastic Measurements of Stress Distribution (Cantor Lectures) (3).

Chemical Industry Club, at 8.—C. Ainsworth Mitchell: Expert Evidence in Criminal Trials.

Royal Society of Medicine (Odontology Section), at 8.—Dr. H. W. Barber: The Relationship of Diseases of the Skin to Dental Infection.—E. C. Sprawson: Further Notes on Dentigerous Cysts.

Hunterian Society of London (at Cutlers' Hall, E.C.), at 9.—W. G. Ball: The Value of Modern Methods of Investigation in the Diagnosis and Treatment of Hæmaturia.

University of Birmingham Chemical Society.—Prof. W. N. Haworth: Some Hetero-cyclic Compounds (Presidential Address).

TUESDAY, March 1.

North Staffordshire Institute of Mining Engineers (in Central School of Science and Technology, Stoke-on-Trent), at 4.—T. C. Maynard: Notes on the Re-opening of a Working District after Spontaneous Combustion.

Royal College of Physicians of London, at 5.—Dr. W. F. Dearden: Health Hazards in the Cotton Industry (Milroy Lectures) (1).

Royal Institution of Great Britain, at 5.15.—Prof. J. S. Huxley: Problems of Animal Growth and Development (5).

Child-Study Society (at Central Hall, Westminster), at 6.—St. John Ervine: The Drama and Education.

London Natural History Society (at Winchester House, E.C.), at 6.30.—Major E. E. Austen: Tse-tse Flies and their Significance to Tropical Africa (Lecture).

Institution of Electrical Engineers (East Midland Sub-Centre) (at University College, Nottingham), at 6.45.—J. R. Beard and T. G. N. Haldane: The Design of City Distribution Systems, and the Problem of Standardisation.

Electrical Power Engineers' Association (Midland Division) (at Chamber of Commerce, Birmingham), at 7.—C. Vernier: Super-Tension Cables.

Royal Photographic Society of Great Britain, at 7.—M. Terry: Northern Australia—An Account of my 1925 Expedition.

Institute of Metals (North-East Coast Section) (at Armstrong College, Newcastle-upon-Tyne), at 7.30.—Annual General Meeting.

Hull Chemical and Engineering Society, at 7.45.—Dr. W. H. Hatfield: Stainless Steel.

Institution of Automobile Engineers (at Royal Society of Arts), at 7.45.—H. R. Ricardo: Some Notes on Petrol-Engine Development.

Röntgen Society (at British Institute of Radiology), at 8.15.

Institute of Chemistry (Annual General Meeting).

WEDNESDAY, March 2.

Electrical Association for Women (at Hackney Electricity Showrooms, 18 Lower Clapton Road, E.5), at 3.—Discussion on Electric Cookers, from the Housewife's Point of View.

Royal College of Surgeons of England, at 5.—Sir Arthur Keith: Recent Researches carried out in the Museum.

Institution of Electrical Engineers (Wireless Section), at 6.—T. L. Eckersley: Short Wave Wireless Telegraphy.

Liverpool Engineering Society (at The Temple, Dale Street, Liverpool), at 6.—J. Wilding: The Mersey Crossings and Industrial Developments.

Institution of Civil Engineers (Students' Meeting), at 6.30.—L. G. B. Rock: The Construction of a Large Cleaning-shed for Electric Trains.

Institution of Heating and Ventilating Engineers (at Caxton Hall), at 7.—Discussion on paper by Dr. Margaret Fishenden on The Effect of Weather Conditions upon the Heat Requirements of a House.

Society of Public Analysts and other Analytical Chemists (Annual General Meeting) (at Chemical Society), at 8.—A. W. Knapp, J. E. Moss, and A. Melley: Cacao Butter Substitutes and their Detection.—Dr. H. W. Bywaters, F. T. Maggs, and C. J. Pool: The Detection of Illipé Butter in Chocolate.—A. F. Lerrigo and A. L. Williams: A Study of the Determination of Saccharin, Colorimetrically and by the Ammonia Process.

Royal Society of Arts, at 8.—U. R. Evans: The Corrosion of Metals at Joints and Crevices.

Eugenics Society, at 8.

Royal Society of Medicine (Surgery Section), at 8.30.—C. Max Page, Dr. Beddard, R. C. Elmslie, and others: Discussion on The Surgical Treatment of Chronic Non-tuberculous Arthritis.

Royal Microscopical Society (Biological Section).

THURSDAY, March 3.

Royal Society, at 4.30.—Prof. W. L. Bragg: The Structure of Certain Silicates.—M. Bentivoglio: An Investigation of the Rate of Growth of Crystals in Different Directions.—M. C. Johnson: Doppler Effects and Intensities of Lines in the Molecular Spectrum of Hydrogen Positive Rays.—W. L. Webster: The Transverse Magneto-Resistance Effect in Single Crystals of Iron.—*Papers to be read in title only*.—R. Mallett: A Vector Loci Method of Treating Coupled Circuits.—H. Gregory and H. Marshall: The Thermal Conductivity of Carbon Dioxide.—Prof. H. S. Allen and I. Sandeman: Bands in the Secondary Spectrum of Hydrogen.—Prof. C. G. Darwin and F. H. Watson: The Constants of the Magnetic Dispersion of Light.

Royal Society of Medicine (Balneology and Climatology Section), at 4.30.—Dr. C. McClure, Dr. Wybauw, Dr. F. Fox, and others: Discussion on The Breakdowns of Middle Life.

Royal College of Physicians of London, at 5.—Dr. W. F. Dearden: Health Hazards in the Cotton Industry (Milroy Lectures) (2).

Royal Institution of Great Britain, at 5.15.—Prof. J. Garstang: The Progress of Hittite Studies (2).

Child-Study Society (at Royal Sanitary Institute), at 6.—G. K. Jones: The Battersea Scheme of Children's Concerts and Cinema Shows.

Institution of Electrical Engineers, at 6.—J. W. T. Walsh: Illuminating Engineering.—H. T. Harrison: The Problems of Public Lighting by Electricity.

Institute of Metals (Birmingham Section) (jointly with Staffordshire Iron and Steel Institute and Birmingham Metallurgical Society) (at Engineers' Club, Birmingham), at 7.—Dr. E. W. Smith: Metal Melting Furnaces.

Society of Chemical Industry (Bristol Section) (Annual Meeting) (at Bristol University), at 7.30.—G. Gray: Science and Industry (Chairman's Address).

Chemical Society, at 8.—R. W. Lunt and R. Venkateswaran: The Decomposition of Carbon Monoxide in the Corona due to Alternating Electric Fields. Part II.—Prof. T. M. Lowry, L. P. McHatton, and G. G. Jones: The Properties of the Chlorides of Sulphur. Part I. Freezing-points.

FRIDAY, March 4.

Royal College of Surgeons of England, at 5.—Sir Arthur Keith: Recent Researches carried out in the Museum.

Royal Photographic Society of Great Britain, at 7.—Pictorial Group Meeting.

Photomicrographic Society (at 4 Fetter Lane), at 7.—A. E. Tonge: Notes on the Eggs of Lepidoptera.

Society of Chemical Industry (Liverpool and Manchester Sections) (at Manchester), at 7.30.—Dr. D. Clibbens: Chemical Control in the Cotton Bleaching Industry.

Junior Institution of Engineers, at 7.30.—Informal Meeting: An Evening with the Old Brigade.

Geologists' Association (at University College), at 7.30.—Dr. R. L. Sherlock: A Correlation of the British Permo-Triassic Rocks. Part II. The Permo-Trias of England and Wales South of the Pennines.

Philological Society (at University College), at 8.—Prof. D. Jones: Cardinal Vowels.

Oxford University Junior Scientific Club, at 8.15.—Prof. R. A. Peters: Nutrition in the Light of Modern Research.

Royal Institution of Great Britain, at 9.—Sir Herbert Jackson: Some Colouring Agents in Glasses and Glazes.

SATURDAY, March 5.

Royal Institution of Great Britain, at 3.—Dr. J. B. McEwen: Beethoven (2).

PUBLIC LECTURES.

SATURDAY, February 26.

Horniman Museum (Forest Hill), at 3.30.—C. Daryll Forde: Ancient Ships and their Modern Descendants.

SUNDAY, February 27.

Guildhall (Eccleston Square), at 3.30.—Prof. J. A. Thomson: The Naturalist's Approach to Religion.

MONDAY, February 28.

London School of Economics and Political Science, at 5.—Prof. H. J. Laski: The Political Philosophy of Spinoza.

King's College for Women (Household and Social Science Department), at 5.15.—J. Fletcher: Principles of Design in Furniture and Decoration.

TUESDAY, March 1.

Bedford College for Women, at 5.15.—Prof. H. H. Turner: Conceptions of the Cosmos in the Galilean and Newtonian Period.

WEDNESDAY, March 2.

University College, at 5.30.—W. H. Patterson: Volta.

THURSDAY, March 3.

King's College, at 5.30.—R. G. Collingwood: The Mind: Æsthetics.

FRIDAY, March 4.

King's College, at 5.30.—C. J. Gadd: Herodotus in Babylon.

SATURDAY, March 5.

Horniman Museum (Forest Hill), at 3.30.—H. Harcourt: Some Poisonous Snakes of India.

SUNDAY, March 6.

Guildhouse (Eccleston Square), at 3.30.—Dr. C. Delisle Burns: Experimental Religion.

SATURDAY, MARCH 5, 1927.

A Representative Body for Science in Great Britain.

THE invitation sent out by the National Union of Scientific Workers to all those who have made science their vocation, to assist in building up an organisation which shall be fully representative of their various interests, may appear to some to be superfluous. They may argue that the functions which it is proposed this representative body should perform come within the scope of the legitimate activities of existing bodies, the various learned societies, propagandist bodies like the British Association and the British Science Guild, and the professional institutions the members of which are engaged in the teaching and practice of science. Others, while prepared to agree with the statement that none of the existing bodies is fully representative of science and the scientific worker, may feel that this is an advantage rather than a disadvantage, in that it is conducive to the freest expression of the will of the individual. They may fear that the establishment of a code of professional ethics, for example, might result in the growth of a narrow professionalism deadly to the spirit of science.

A hundred years ago similar objections were raised to the formation of the British Medical Association. Some qualified physicians, surgeons, and apothecaries on one hand, and all the quacks on the other, regarded this body with the greatest disfavour, the former because they resented the implication that the existing bodies were not all-sufficient and wished to safeguard their right to control their respective branches of the medical profession, the latter because they were fearful of the material consequences to themselves. Yet it cannot be seriously suggested that the peculiar form of professionalism which was established mainly through the initiative and instrumentality of the British Medical Association has not been of the greatest advantage to the members of that profession and even more to the public. It must be acknowledged that the type of professionalism which insists that the results of ameliorative research should be made available to the whole world, which insists also that the discoverers themselves shall not derive any immediate and direct pecuniary benefit from them, is expressive of the highest ideals of service and calculated to attract to the profession some of the finest spirits of the age. Neither can it be said that the prestige of the Royal Society of Medicine, the Royal College of Physicians or the Royal College of

Surgeons, or the faculties of medicine of the universities of Great Britain suffered through the activities of the democratically constituted body: actually their prestige was enhanced. The medical profession is practically a self-governing body, members of the profession predominate on the General Medical Council, and the Government puts large funds at the disposal of the Medical Research Council, most of the members of which, and the chief administrative officer, are also members of the medical profession. Moreover, they act in an executive capacity, and not merely an advisory capacity like the scientific members of the Committee of the Privy Council for Scientific and Industrial Research.

The suggestion that the proposed body for science is superfluous is disposed of by the signatories and supporters of the present appeal: among them are some who have held or are at present holding high offices in learned societies and professional institutions. In another category is the vague fear that such a body would tend to warp the spirit of the individual scientific worker or restrain his freedom of action in any way. Much would depend on the character of the restraint. It might quite reasonably recommend its members not to apply for appointments where low initial salaries were not compensated for by the prospects of a moderate competency later, or where other conditions of service were notoriously bad. But it is difficult to imagine in what other ways it would fetter the judgment of an individual. It can scarcely be imagined that it would demand a thirty-six-hour week, or that it would exhibit that peculiar vice of modern trade-unionism—the excessive demarcation of function—or even that it would proscribe certain types of research. It is obvious that it must do none of these things. On the contrary, one of its most important tasks might be the freeing of research workers in certain industrial undertakings and government departments and State-aided institutions from many of the unnecessary and irritating restraints from which they suffer to-day—conditions which are only possible because of the lack of organisation among the victims. Just as the British Medical Association broke down the narrow professionalism and exclusiveness of the older sectional organisations, so could the proposed body promote unity among the many distinct and overlapping sectional bodies in science.

It is a little unfortunate that the general newspapers, in commenting on the appeal, have unduly stressed its material aspect, and almost entirely ignored the wider aims outlined. Naturally, a body which exists for the purpose of furthering and protecting the interests of scientific workers must do all in its power to bring about an improvement of the salaries and other conditions of service of its members. The shortage of men and women of the first rank for research has been noted in nearly every report on scientific research which has lately been published, and this shortage is attributed to the slender material attractions of a career which demands not only a rare type of mind, but also the utmost perseverance and self-training. Amateurs of the type of Cavendish and Darwin are few in number. The ranks of research workers have now to be filled by those to whom science must be a profession. "Human nature," stated the *Observer* last Sunday, "would have to be more exalted than it is to secure that the highest gifts would always be devoted to the service of knowledge for a reward much lower than accrues to mediocre grades of business ability." Clearly, it is the duty of the profession of science to ensure that the value put upon its services is sufficient to attract the highest type of recruit.

More is, however, demanded. Scientific workers must be valued not only for their achievements in harnessing the forces of Nature to the service of man, for giving him a greater measure of control over his environment by their successes in the combat against the diseases which afflict human beings, animals, and plants; for the material blessings they bestow on communities, or for the potency of the lethal weapons they have devised. They must be valued for their greatest achievement, the habit of mind which their patient and persevering observations and inquiry has engendered. They can bring to the examination of world problems an outlook which cannot rest content with partial and incomplete solutions. Hitherto, they have been denied the opportunity of directing or sharing the control of the affairs of a civilisation for which they are mainly responsible. Again, the remedy lies with scientific workers themselves. They could, if they were united in a great resolve, make the nation understand the contributions they have to offer to its problems, social problems, industrial problems, problems of finance. It is essentially their function, and not primarily that of a government department, to state the aims and the needs of science, and how best those needs can be met. It is their paramount duty to insist that science should be adequately represented in the councils of the nation, and they could best accomplish that end if they presented the appearance of a disciplined force instead of unorganised or inchoate and impotent factions.

It may be thought that unity in science will be best accomplished by the formation of a federal council upon which the various learned societies and professional institutions can be represented, rather than by a body aiming at becoming representative of these varied interests on the basis of individual membership. Scientific workers must realise, however, that to be effective, a federal council must have executive authority. It must be in a position, should the necessity arise, to take action involving each and all of the constituent bodies without direct reference to them: in other words, the constituent bodies must delegate large powers to their representatives. The breakdown of the Conjoint Board of Scientific Societies was largely due to the reluctance of the various societies to grant their representatives any such authority; and, in the end, to the Royal Society deciding not to support an appeal to Government for increased aid for the publication of scientific papers. Other attempts to obtain concerted action by the various societies have been equally unfortunate. On the other hand, if scientific workers are of opinion that a representative body able to speak with the authority of the majority of men and women professionally qualified for scientific service by their university degrees or other qualifications, is desirable for the advance of science and civilisation, they should make their wishes known.

Modern Geophysics.

Lehrbuch der Geophysik. Herausgegeben von Dr. B. Gutenberg. Lieferung 1. Pp. 176. 9·75 gold marks. Lieferung 2. Pp. 177-400. 13·80 gold marks. (Berlin: Gebrüder Borntraeger, 1926.)

GEOPHYSICS has now its 'Lehrbuch'; at any rate, it has two-fifths of one at the moment of writing, and the remaining instalments are promised for an early date. The difficulty that no single author can cover the whole subject has been met by obtaining the collaboration of a number of authors, and the whole is under the editorship of Prof. B. Gutenberg, whose distinguished work has already led to great advances in seismology and the study of the propagation of sound. The first two parts are by Profs. A. Born, E. A. Ansel, A. Sieberg, J. Bartels, and Gutenberg himself.

The opening chapter consists of three pages on cosmogony by Born, and gives short summaries of the nebular and planetesimal hypotheses of the origin of the solar system. It is rather unfortunate in mentioning work of mine in support of the planetesimal hypothesis; though the hypothesis I favour starts with the same initial assumptions as the planetesimal hypothesis, to the authors of which I have often expressed my indebtedness, it happens that the principal modification I have found necessary consists in dispensing with the planetesimals, and consequently a different name is needed for the theory I have advocated. The author decides that the primitive earth was fluid; this agrees with my own views, but not with the original form of the planetesimal hypothesis.

Prof. Born then gives a condensed account of the classification of rocks, with much useful information about their composition, mechanical properties, and thermal conductivity. Such information in an accessible form has long been needed; most analysts seem to think that it is much less important to know the density of a rock than whether it contains 0·3 or 0·5 per cent. of titanium. On p. 8 aluminium has somehow escaped mention as a constituent of felspars.

The composition and radioactivity of meteorites are then described, and Prof. Born goes on to the abundance of the chemical elements in the crust. The greater density and basicity of suboceanic rocks in comparison with continental ones are brought out. Data concerning radioactivity are given, but thorium contents are given only for basalts. A very good account of methods of determining geological time follows; De Geer's method for post-glacial time is included. The main geographical features of the earth are described in the next chapter.

There is a remark on p. 52 that the melting-point of basaltic rocks at atmospheric pressure is about 200°-300° C. lower than that of granite ones, which is given as 1100°. F. W. Clarke gives 1240° for granite, and values from 1060° to 1250° for basalt ("Data of Geochemistry," 1924, 298-301). J. H. L. Vogt gives 1250° for the crystallization point of gabbro, which is chemically similar to basalt, and 1000° for granite ("Economic Geology," 1926, 207-233). The latter estimates refer explicitly to dry material, but it seems to be generally believed by geologists that in natural conditions the melting-point of granite is more affected by water than that of basic rocks. A reconsideration of the data on this question is overdue; such a conflict of opinion on some of the most important experimental data of geophysics should not be allowed to persist.

A useful discussion of gravity and isostasy by Prof. Ansel follows. The account of the differences between the Airy, Pratt, and Hayford views of isostasy is clear and good, and there is a short account of the figure of the earth. The method of reduction of gravity observations is described, with special application to European data.

Movements of the crust are then treated by Prof. Born. Those on a continental scale are treated shortly, and then there is a description of the processes involved in the formation of mountains, with many excellent illustrations and accounts of relevant experiments. Pp. 122-125 are concerned with objections to the contraction hypothesis in general, not merely to the thermal contraction hypothesis. All seem to me quite unsound. One is that the strength required in the crust if it is to support itself like an arch without resting on the interior is many times the crushing strength of rock materials. Of course: but who has said that the crust had to become detached from the interior before it could be crumpled?

Phenomena of denudation and vulcanism are discussed in the next two chapters, mainly quantitatively.

The section on earthquakes in relation to geology is by Prof. Sieberg. It is concerned mainly with macroseismic data; there are several striking illustrations showing the fractures, rotations, and other disturbances produced in the neighbourhood of an earthquake. In addition to the ordinary scales of intensity, Prof. Sieberg gives one of his own adapted to disturbances felt at sea. The relations of earthquakes to volcanic and tectonic disturbances, and the physical processes involved in earthquakes, are then treated at considerable length.

The chief types of seismographs are described by Gutenberg in the next chapter. A novelty is an account of the torsion seismograph of Anderson and Wood, which depends on a cylinder mounted on a vertical wire in such a way that its centre of mass is not on the wire. Horizontal disturbances of the ground displace the wire and cause the cylinder to rotate about it. Then Gutenberg proceeds to consider the information yielded by the records of distant earthquakes. Most of his work on this subject has already been published, but not in so convenient a form, and it is so important that a connected account of it is invaluable. On pp. 245-6 tables derived from observation show the times of transmission of the direct *P* and *S* waves through the earth. These times are mostly rather shorter than those obtained by Zöppritz and still used as a basis for reductions by Turner; the differences for *P* reach about 12 seconds when the epicentral distance is 90°, while those for *S* are on the whole rather less.

Gutenberg's times have been derived from a discussion of many more earthquakes than were available when Zöppritz wrote, and have been supplemented by the amplitudes of the displacements observed, which afford a valuable check on the times measured directly. In addition, he has used these times to calculate the times of transmission of the various other waves theoretically possible. Following up some earlier work of R. D. Oldham, Gutenberg has found that the earth has an extensive central core where the *S* (distortional) wave is not transmitted, and the *P* (compressional) wave travels much more slowly than in the outer parts. This opens up the possibility that any wave incident on the boundary of this core will be broken up into three new waves—compressional waves in both shell and core, and a distortional wave in the shell. Waves incident on the outer surface, again, in general give rise to both compressional and distortional reflected waves. The waves transmitted into the core can undergo further separations when they emerge from it, so that on the whole a very complex picture is presented of the motion produced by a single earthquake shock. In the figure on p. 247 there are 16 curves showing the times of transit of waves to different distances; originally only three of these were empirical, and all the others are direct inferences from these three by means of the ordinary laws of wave propagation. I believe I am right in saying that every one of these curves has been verified by tracing the derived waves on actual records.

Near earthquakes and surface waves are then discussed, with several other interesting seismological questions, and Prof. Gutenberg then passes on to water waves and tides. The bodily tide, precession and nutation, and the variation of latitude are well, if somewhat briefly, discussed. The last twenty-three pages form the beginning of Dr. Bartels' article on terrestrial magnetism and related phenomena.

That the book should be in the possession of every geophysicist need scarcely be said. Nevertheless one feels at times that the authors' style is cramped for lack of space, and that geophysics is too large for one text-book, even one of a thousand pages. Still the amount of information compressed into the first four hundred pages is astonishing.

Harold Jeffreys.

Intellectual Activities in France.

Statistique intellectuelle de la France: tableaux relatifs à l'enseignement public, aux bibliothèques, aux spectacles, aux publications, préparés sous les auspices de l'Institut International de Coopération Intellectuelle et de l'Institut de Statistique de l'Université de Paris. Par Tatiana Beresovski-Chestov. Année 1923–24. Pp. vii + 124. (Paris: Les Presses universitaires de France, 1926.) 35 francs.

USUALLY, if one wants to discover detailed and comprehensive statistics concerning all kinds of educational machinery from primary, secondary, technical, and art schools to libraries, and even theatres, they must be sought in many (and often elusive) publications. Here they appear in one volume—a recommendation in itself.

It would be easy, of course, to succumb to the usual temptation presented by such a volume, namely, to compare its figures with those available in Great Britain. That is, however, a temptation we shall resist for three reasons. First, it is very difficult to make trustworthy comparisons where various parts of the machinery and their several objectives do not exactly correspond to those in Britain. Secondly, considerations of space would force us to select only those parts of the machinery in which we are specially interested; and, lacking the exact correspondence already mentioned, we would merely confirm the haters of statistics in their sweeping assertion that figures can be made to prove anything. The third reason, however, is the most important. It is that the idea behind this volume is not merely the presentation of many figures which uncontrolled enthusiasts may use to show how much more should be done in the fields which interest them most, or which railers against taxes may use to show in what manner public money is wasted. Nor is it, in the slightest degree, a defence of administration. It is a definite recognition that departmental statistics afford no real evidence of the intellectual progress of a country.

Not yet is it sufficiently realised that education is a process by no means confined to the school. There are libraries and pictures; theatres and cinemas; churches and museums; books and companions: there are also thoughtless parents and heedless employers; and who will doubt the enormous influence of the Press? All these, and countless other important and often unnoticed influences, go to make up the forces which determine intellectual progress. Only when their interlacing and interdependent qualities become more clearly perceived will the waste and sprawling disorder of the methods by which we try to advance become capable of scientific handling and direction.

To the question of how is this perception to be achieved, there are doubtless as many answers as there are difficulties to be overcome; and one of the many difficulties arises out of our inevitable drive towards specialisation—in education no less than in other fields. As the specialist becomes more immersed in his own developing activities, he often becomes less inclined to do more towards co-operation than to utter phrases of pious generalisation in public, while in private he is apt to become contemptuous of what he regards as intrusion. To criticise this attitude too severely is futile. It is, after all, quite comprehensible and is based upon a sound enthusiasm which is of vital importance to the swift destruction of the varied barriers against man's completer knowledge of his environment. Nevertheless, it must never be forgotten that specialisation achieves its highest value only by reason of its relationship to the great unity of knowledge which serves mankind.

In Great Britain the tendency to draw together activities in order to obviate lonely and superfluous endeavour has recently found practical expression—particularly in the direction of securing a clearing-house for all kinds of specialised information—in the formation of the Association of Special Libraries and Information Bureaux. On the statistical side, it is in the category of such movements that we would place the present volume. It does not pretend to be so complete as might be desired. It is, indeed, frankly admitted that the lack of certain information makes the work fall short of the ideal which has inspired it. Its value, however, cannot be over-estimated, and we shall look forward to the next volume (1924–25) which is already promised. In the meantime we cannot do better than conclude by quoting a passage from the introduction:

> "Une publication comme celle-ci fait comprendre à quel point nous sommes loin de donner au public les renseignements qui serviraient à évaluer la grandeur et la nature de la production française dans les sciences, les arts, les lettres et l'enseignement et en général l'importance de l'activité intellectuelle de la France. L'Institut International de Coopération Intellectuelle a fait savoir qu'il demanderait à tous les États de bien vouloir examiner les moyens de multiplier les relevés statistiques relatifs à la vie intellectuelle, suivant un plan qu'il leur proposera. Il est certain que l'apparition simultanée de statistiques bien faites sur l'activité intellectuelle de chaque pays pourrait singulièrement servir au progrès général."

Gmelin's 'Handbook.'

Gmelin's Handbuch der anorganischen Chemie. Achte völlig neu bearbeitete Auflage. Herausgegeben von der Deutschen Chemischen Gesellschaft. Bearbeitet von R. J. Meyer. Unter beratender Mitwirkung von Franz Peters. (1) System-Number 13: Bor. Pp. xix + 142. n.p. (2) System-Number 5: Fluor. Pp. xvi + 86. n.p. (Leipzig und Berlin: Verlag Chemie, G.m.b.H., 1926.)

INORGANIC chemistry has been so completely transformed within recent years that long before the completion of the seventh edition of Gmelin's well-known treatise, an entirely re-fashioned and comprehensive work, showing but little resemblance to the older editions, has been undertaken by the German Chemical Society. Except for the non-valent gases, which are all grouped into the first section, each element is being issued as a separate part under a specific 'system-number' (not identical with its atomic number), and it is expected that seventy separate parts will ultimately be issued within a decade and that the whole will form twenty-two volumes. Compounds of two elements will be found under the element of the higher serial number. Thus a particular subject will often be divided, *e.g.* boron carbide falls under carbon, whilst boron sulphide falls under boron, but an alphabetical index of subject matter becomes unnecessary. At the beginning of each section on one element there is a full table of contents, a list of abbreviations, an alphabetical register of journals to which reference is made, and also a complete list of system-numbers to facilitate the location of a compound in the complete work.

(1) In order to adhere to the general plan and at the same time to impart to the section on boron a certain independence, it has been found advisable to include condensed but freely annotated accounts of certain topics, which will be discussed in fuller detail at a later stage, *e.g.* several pages are devoted to a description of metallic borides in general, to heteropolyboric acids and organic complexes, and to perborates. The literature has been exhaustively studied—not merely transferred from earlier editions—to the end of 1925, but an addendum of seven pages includes some later material. Several diagrams are inserted in illustration of the relation between electrical conductivity and temperature, the influence of alcohols on the solubility of boric acid, etc.

(2) The section on fluorine is illustrated with excellent diagrams of the apparatus used by Moissan in 1887 in isolating the element, and of the modifications used later by Argo, Meyer, and Sandow, and by Simons. The history of the element, the general and physical properties, electrochemical behaviour and preparation of its compounds, are all dealt with in detail and a considerable amount of attention is given to analytical methods. A comprehensive survey of the results of atomic weight determinations from 1814 to 1925 is included. Amongst optical properties are found values of atomic refraction, wave-lengths in the arc and spark spectra, and even quite recent direct measurements of the *Kα* line obtained by X-ray analysis. The literature has been revised to the middle of 1926. Complex fluorides are catalogued in eight (periodic) groups, with formulæ and a full list of references.

Each part is bound in stiff-paper covers and clearly printed. When complete the 'Handbuch' will be an indispensable work of reference to the specialists in both pure and applied inorganic chemistry, and it will assuredly lighten the tedious labour involved in searching the literature.

Electrometric Methods.

(1) *Hydrogen Ion Concentration: its Significance in the Biological Sciences and Methods for its Determinations.* By Prof. Leonor Michaelis. Vol. 1: *Principles of the Theory.* Authorised translation from the second revised and enlarged German edition by Dr. William A. Perlzweig. Pp. xiv + 299. (Baltimore, Md.: Williams and Wilkins Co.; London: Baillière, Tindall and Cox, 1926.) 22*s.* 6*d.* net.

(2) *Potentiometric Titrations: a Theoretical and Practical Treatise.* By Dr. I. M. Kolthoff and Dr. N. Howell Furman. Pp. xii + 345. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1926.) 22*s.* 6*d.* net.

(3) *Les ions d'hydrogène: signification, mésure, applications, données numériques.* Par W. Kopaczewski. Pp. ix + 322. (Paris: Gauthier-Villars et Cie, 1926.) 70 francs.

(1) OF recent years the application of potentiometric methods to the determination of conditions of equilibria in aqueous solutions as well as to quantitative analysis has assumed proportions of no inconsiderable magnitude, and has thus created a demand for text-books on the subjects. To English readers the appearance of the second edition in English of Michaelis's well-known volume will prove a welcome addition to the text-books, few in number, which are universally appreciated. It is unfortunate that in this edition the

erroneous calculations of Ghosh, pp. 117-120, on the conductivity of strong electrolytes, have not been eliminated or replaced by those of Milner and Debye and Hückel. The book is specially valuable, as it is the only one of which the reviewer is aware in which the various types of electrification which can be produced at interfaces are described and discussed. In biology, at least, phase boundary membrane and electrokinetic potentials appear to be of the greatest significance.

(2) The volume of Kolthoff and Furman covers a somewhat different field. Here emphasis is laid on the more recent work on oxidation reduction potentials as well as the employment of metal electrodes in volumetric potentiometric analysis. The book is very well written and the conditions necessary for accurate work fully described. Possibly the weakest portion of the text is the descriptive portion in Chapts. vii. and viii. There are many simple and accurate potentiometers now on the market, such as that constructed by the Cambridge Instrument Co. designed specially for this work. These are now employed almost universally in research laboratories and works, and a short description of such might well replace some of the more complicated but no more accurate systems described. It is interesting to note that adsorption of precipitating ions may cause quite serious errors in the end points of various volumetric titrations in which precipitates are formed.

(3) Kopaczewski has confined himself to the potentiometric and colorimetric methods for the determination of hydrogen ions. The theoretical discussion on the nature of electrolytic dissociation and on the various activity coefficients is treated very inadequately, whilst the remainder of the book, chiefly experimental in character, follows the usual course. Eric K. Rideal.

The General Theory of Relativity.

Les équations de la dynamique de l'éther. Par Prof. Henri Eyraud. Pp. iii + 67. (Paris: Albert Blanchard, 1926.) 12 francs.

THIS monograph, dealing with the general theory of relativity, has a particular interest of its own in so far as it deals with a novel application of a recent generalisation of M. Cartan to the dynamics of the ether. Besides a brief historical introduction of three pages, and an appendix of nine pages on the technique of space and time measurements, there are two chapters, one of nearly thirty pages, dealing with the geometry of the spaces of the relativity theories, and another of nearly twenty pages dealing with the application of the principle of least action to the theories of gravitational and electromagnetic fields.

The first chapter works out, by traditional methods, the generalisation of M. Cartan already referred to, in which the components Γ^i_{jk} of the affine connexion in Weyl's geometry are no longer assumed to be symmetric in the two lower indices. Consequently a new true tensor arises, namely, the *torsion* $\Lambda^i_{jk} = \Gamma^i_{jk} - \Gamma^i_{kj}$, which plays an important part in the geometry of the generalisation of Weyl's space. The second chapter, which is the novel part of the monograph, introduces an action integral after the fashion of Mie and Weyl, in which the action density is assumed, initially, at all events, to be a function of two tensors of the second order: one, the skew symmetric electromagnetic tensor, which is the rotation of the contracted components of the affine connexion, Γ^k_{jk}, and the other, the gravitational tensor, which is the symmetric part of the contracted Riemann-Christoffel tensor, R_{ij}.

The ether thus defined is deduced from a Riemann space by a projective conformal transformation, and that the vector potential of the electromagnetic tensor, apart from a numerical factor, can be identified with the contracted torsion tensor $\Lambda_j = \Lambda^k_{jk}$. With the action density so far defined as a function merely of the electromagnetic and gravitational tensors, the ether is empty, that is, devoid of electric charge and current. When, however, the action density in addition is an explicit function of the contracted torsion tensor, the current vector appears as the partial differential coefficient of the action density with respect to the new tensor. A plausible assumption as to the form of the action density in the general case leads to an energy tensor of the usual type, with a part representing the electromagnetic energy, another part representing the electronic energy, and generally a third complementary part, which has the character of a pressure. The additional hypothesis that the action density depends mainly on the gravitation potentials, g_{ik}, whilst the influence of the electromagnetic and current terms is comparatively small, leads to the results that (1) the Lorentz electrodynamics holds, (2) the atoms are bounded universes with constant total curvature, and (3) the complementary energy is absent, both in the ether and the atoms.

The monograph is very concise, but offers no particular difficulty for readers familiar with the technique of the general theory of relativity. For such readers it will prove to be most interesting.

The Atomic Weight of Silver.

In Nature of Dec. 11, 1926, reference is made to the determination of the atomic weight of silver (*Trans. Chem. Soc.*, 1926, p. 2510) by H. Brereton Baker and H. L. Riley, who, by determining directly the ratio Ag : O in pure silver oxide have obtained the value 107·864 ± 0·0013. This work, carried out with the greatest ingenuity and with care and exactitude such as has only been reached by Th. W. Richards and his school, is of cardinal importance. As I have the honour to be chairman of the Sub-Committee for Atomic Weights of the International Commission on Chemical Elements, I have perhaps the right, as well as the official duty, of offering a few critical remarks. I may be allowed to add that I have studied the literature of atomic weights for fifty years and I was the first to propose, in 1888, the adoption of O = 16 as the standard of atomic weights. A like proposal was made almost simultaneously by Venable in America, and, as is well known, this has become the established practice. As the atomic weights of elements cannot as a rule be determined directly in relation to oxygen, secondary standards are required, and the most modern work published by Richards and his school is being carried out by finding the ratios $x\mathrm{Ag} : \mathrm{RCl}_x$ or $y\mathrm{Ag} : \mathrm{RBr}_y$ to determine the atomic weight of R.

The atomic weight of silver has hitherto been a relative quantity, depending upon the atomic weights of other elements, especially chlorine, potassium, lithium, and nitrogen. As I have shown in critical articles in Abegg's 'Handbook,' it must lie between 107·876 and 107·871, and this view was adopted by the International Commission for Chemical Elements in 1925. In this way the classical value 107·930 of Stas (1865) (declared by Ostwald to be exact to the limit ±0·004 !) was superseded.

The best determination of the atomic weight of silver published by the Richards school led them to regard the value 107·876 as probably the best, and I agreed with them.

The acceptance of the results given by Baker and Riley would affect the whole series of results of the Richards school, and if we accept 107·864, chlorine would become 35·452–35·450 and nitrogen 13·999, values highly improbable having regard to the whole chemical and physical-chemical work bearing upon these elements.

After a very careful study of the paper of Baker and Riley, I beg permission to point to a possible experimental error which appears to have been overlooked by the authors. They decomposed silver oxide by heat and fused the metallic silver so obtained in an atmosphere of hydrogen. They do not seem to have considered whether silver is not volatile at its melting point, 960°·5, or a little above this temperature. Now Stas distilled silver with the oxyhydrogen flame, and I found in my work on the atomic weight of tellurium that it may be easily distilled by the flame of air and coal gas. Even on an open support of lime, silver is volatilised by using an ordinary blowpipe, a copious brown deposit (of oxide or possibly colloidal silver) being formed. On heating the metallic silver obtained by the method of Stas in a tube of the hardest Bohemian glass in the vacuum of a Sprengel pump, I found that at a dull red heat a distinct ring of fine particles of metallic silver was deposited on the cooler part of the tube. Silver, therefore, must have a small but appreciable vapour tension even at 400°-500°. Prof. H. Krepelka has observed repeatedly that on heating the purest, finely divided ('atomic weight') silver to its melting point in hydrogen, a distinct sublimate of small globules of metallic silver was formed on the cooler parts of the silica tube. From this I conclude that metallic silver is volatilised to a small extent at a temperature near 1000° to which Messrs. Baker and Riley heated it and fused it in hydrogen. Thus they would find their atomic weight too low.

The question arises what would be the magnitude of this source of error. If we assume the real value of the atomic weight to be 107·871 or 107·876, we can recalculate the data. I have done this, and find that if we attribute the difference of Baker and Riley's value from the value 107·871, the loss of silver on fusing would lie between the limits of 0·13 milligram and 0·006 milligram; if we take silver as 107·876, the loss would lie between the limits of 0·20 milligram and 0·06 milligram. If we take the mean atomic weight 107·864 given by Baker and Riley, the losses would be respectively 0·08 milligram and 0·14 milligram.

These quantities are so small that the silver corresponding to them would not be visible in any way in the quartz tube. I confess that I am surprised to find the above values so small, but I offer an explanation and give details in the full paper that will be published elsewhere.

May I say, in conclusion, that many years ago I contemplated a direct determination of the ratio of the atomic weights of silver and oxygen by reduction in hydrogen or in a mixture of hydrogen and nitrogen at the lowest possible temperature, but I could not carry out this most difficult and delicate work alone.

Bohuslav Brauner.

Bohemian University, Prague.

Thanks to the courtesy of the Editor of Nature, we are able to reply at once to the very kindly expressed criticism of Prof. Brauner. He considers that there is a possible source of error in our recent determination of the atomic weight of silver owing to the loss of traces of silver, by volatilisation, during its final melting in hydrogen. It is certain that, at the temperature of 900°, silver does give off some vapour, but we are convinced that no silver left the weighed tube. The silica tube was 17 cm. in length, not more than half of which was heated in the furnace. The rest, shielded from the heat of the furnace by asbestos board, together with the ground joint and narrow glass tube, has a length of 20 cm. They were kept cool by fanning during the whole time of the experiment. The current of hydrogen was very slow, about one bubble in 3 seconds.

It is not possible that the silver, which may volatilise at 900°, should escape in the state of vapour. If it escaped at all, it must have been in the form of fine particles of solid metal, and it seems almost inconceivable that no deposit should ever have been observed throughout the eight years during which the experiments have been going on. In the last eighteen determinations the same pair of silica and glass tubes has been used, and microscopic examination fails to reveal any trace of deposit on the part of the silica tube which was cooled, or in the glass tube. A more certain proof, however, is given by the weighings. In each determination the silver was melted several times in the silica tube until its weight was constant to one or two hundredths of a milligram. If there had been any such loss as Prof. Brauner has suggested, such constancy could never have been attained; the weight of the tube would have shown a constant diminution.

The knowledge of the atomic weight of silver is, as Prof. Brauner says, of such importance, that we have begun a new series of experiments to investigate the volatility and condensibility of silver.

A New Method of Measuring the Absolute Surface Area of a Metallic Catalyst.

IN a previous communication (NATURE, vol. 118, p. 730; 1926) it was shown that simultaneous measurements of the electrical conductivity, and the thickness of the oxide layer on a film of metallic copper supported on china-clay rods, enabled the fractional decrease in surface area on sintering to be evaluated.

The thickness of the oxide film was measured by observation of the surface colour. These results give directly the equivalent air thickness of the oxide film, but to convert them into absolute measure the refractive index of the film must also be known. The mineral cuprite, cuprous oxide, has a refractive index of 2·85 and is cubic; whereas cupric oxide, occurring in the mineral kingdom as tenorite, is anorthic, having values of the refractive index of 2·63 for red light, and 3·18 for blue. Cuprite is translucent, having a red colour; tenorite is more opaque, occurring in scaly black crystals.

The colours shown by the oxide films are so marked that it is evident that in very thin films the absorption is almost negligible in amount. Since the oxide film is of higher refractive index than the air above it, the dispersion will tend to exaggerate the colours shown by films of a given thickness. The film is backed by metallic copper, and it is assumed that the path difference is caused by the passage of the light from the top of the film to the reflecting interface at the bottom and back again. With substances of such high refractive indices, the light in the film will be practically normal to the film in spite of the varying angles of incidence.

Let S = the surface area of the metal forming M grams of oxide spread over the china-clay support;
C = the electrical conductivity of the film;
q = equivalent air thickness of the oxide film;
μ = refractive index of the oxide;
ρ = density of the oxide;
k_c = initial value of the constant in the parabolic law for the fall in conductivity;
k_q = initial value for the equivalent air thickness.

Then the rate of formation of the oxide as a fraction of the total oxide possible

$$\frac{\rho . S}{M . \mu} \cdot \frac{dq}{dt}$$

is equal to the rate of disappearance of the metal, expressed similarly, *i.e.*

$$\frac{1}{C} \cdot \frac{dC}{dt}.$$

Hence we have

$$\frac{S}{M} = \frac{dC/dt . \mu}{dq/dt . C . \rho} = \frac{\mu}{\rho . C}\sqrt{\frac{k_c}{k_q}} . \quad . \quad . \quad . \qquad (1)$$

For an activated copper film the following values were found, k_c and k_q being measured at 210° C.:

$k_c = 1{\cdot}52 \times 10^{-2}$; $k_q = 2{\cdot}50 \times 10^{-10}$; $\mu = 2{\cdot}85$ (mean); $c = 0{\cdot}64$; $\rho = 6{\cdot}3$.

Therefore S/M = 5500 sq. cm. per gram of metallic oxide formed.
= 6900 sq. cm. per gram of film.

The area of the supporting china-clay rods for each gram of metallic film was 3200 sq. cm.

It is now possible to complete the comparison of the surface activity of pure electrolytic copper with that of activated reduced copper (*Proc. Roy. Soc.*, A, vol. 110, p. 285; 1926). 2000 sq. cm. of electrolytic copper had an activity that was imperceptible at 370° C., whereas the activity of about 70 sq. cm. of reduced copper was easily detected at 200° C. From the temperature coefficient of the reaction the activity of 540,000 sq. cm. of electrolytic copper would have been imperceptible at 200° C.; hence reduced copper has an activity that is at least 8000 times greater than that of electrolytic copper.

The activity of the smooth surface is very small indeed when compared with the reduced product.

These results, while showing very clearly the order of magnitude of the surface presented by reduced copper, cannot yet be regarded as accurate determinations until the growth of the oxide film has been studied by spectrometric methods. This research is now proceeding.

Cambridge.

Spectrographic Observations of the Second Green Line of the Auroral Spectrum.

IN previous papers on the origin of the auroral spectrum, and recently in a letter to NATURE of Dec. 4, 1926, I have directed attention to the existence of a second green line lying in the region of about λ5230, which should correspond to the line, or rather group of lines, N_2, of the spectrum from solid nitrogen.

As stated in my letter to NATURE, this second auroral line is usually extremely faint and has only occasionally been observed with spectroscopes; in consequence, various observers have found values of the wave-length which differ within fairly wide limits.

On account of the faintness of the line, and also of the fact that the usual photographic plates have a minimum of sensitiveness in this region, I was not able during the early years of my work to obtain this line on my plates.

On a spectrogram made last autumn, however, on a panchromatic plate, I obtained for the first time, after an exposure of forty northern-light hours, this second line; but it was too faint for accurate measurements. The wave-length obtained was 5223.

After this spectrogram had been taken I was able to obtain a sensitiser which gave the plates a high sensitivity in the region wanted. The first exposure with this plate was made in a small spectrograph with fairly high light power and a broad slit. It was exposed at the Geophysical Institute of Tromsø for fifteen effective northern-light hours. On this spectrogram, which gave the ordinary auroral lines much over-exposed, I also now obtained this second green line very well marked on the plate.

The accompanying reproduction (Fig. 1) shows the strong green auroral line marked by *a*, the second green line by *b*, and the strongest lines of the negative band spectrum by *c*, *d*, *e*.

It will be noticed first of all that the second green line is not sharp; although much weaker than the other lines, it covers a greater part of the spectrum. Measurements showed the breadth of the second green line to be 0·22 mm., while that of the other lines, although more strongly exposed, was only 0·15 mm.

From this we can conclude that what is called the second green line is not a single line, but consists of a group of lines.

As stated in my previous letter to NATURE, this is also the case with the N_2 line from solid nitrogen. This fact, which has also been confirmed by McLennan, was taken by him to be an argument against my theory. We see, however, that the spectrogram obtained for the second green line, on the contrary, in this respect has confirmed my view with regard to the origin of the auroral spectrum.

On account of the small dispersion and the broad slit we cannot at present find the wave-length of the various components of the second green line; we have only been able to measure the wave-length of the maximum and limits of the band obtained by our plate. The limits are λλ5220-5269, and for the maximum we find λ5238. On account of the small dispersion, errors of a few angstroms are not excluded.

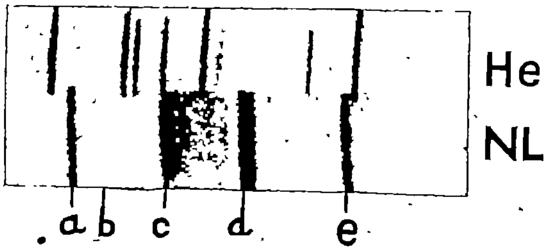

FIG. 1.

Comparing this result with those obtained for the luminescence from solid nitrogen, it is of interest to notice that when small quantities of solid nitrogen are condensed in a solid system of inert gases, we find one of the components of N_2, which in certain cases is dominant, to have wave-lengths of λλ5236-5239, *which within the limits of experimental errors correspond to the wave-length found for the maximum of the second green auroral line.* L. VEGARD.

Physical Institute, Oslo, Feb. 11.

Biological Fact and Theory.

PROF. JOHNSTONE'S letter in NATURE of Feb. 26 suggests an analogy. I happen for my sins to be gifted with very poor mathematical powers. Like him, also, on this account I "feel that I may be missing something that will help in an understanding" of the scientific problems with which mathematics are concerned. But I do *not* therefore attempt to belittle mathematical physics as Prof. Johnstone attempts to belittle the results of Mendelism.

He asks "what are the fundamentals of genetics?" The fundamentals of genetics to date are, I take it, the laws of segregation, independent assortment, and linkage; the proof that the chromosomes carry the genes, and that the genes are arranged in linear order; the genetical results of heteroploidy and chromosome aberrations; the individuality of the chromosomes (as, of course, complicated by crossing-over); the normal chromosomal determination of sex; the theory of genic balance; the facts concerning multiple allelomorphs, and multiple, modifying, and lethal factors; the new insight provided by neo-Mendelian methods into species-crosses and into the effects of inbreeding and cross-breeding; the origin of certain variations by point-mutation, chromosome-mutation, genome-change, deficiency, duplication, balanced lethals, and abnormal crossing-over; the demonstration that Mendelism and biometrics are not opposed; the fact that no development is possible at all in the absence of at least one haploid set of chromosomes; the demonstration that genes often determine the *rate* of definite developmental processes. There are doubtless other points which I have forgotten in this hasty survey; but it is absurd to imply that this is not a very considerable achievement and an "ample foundation" for future work.

Prof. Johnstone and Prof. Walker both seem to think that the sum of the genes *cannot* be responsible for the development of the "organism as a whole" or large characters such as the head. But has Liverpool never heard of Boveri's experiments on dispermic sea-urchin eggs, published exactly twenty years ago? It may be at present impossible to understand how the sum of the genes is responsible for the development of the organism as a whole, but Boveri made it reasonably certain that it is actually the case.

However, the work of the experimental embryologists, of Child, and of Goldschmidt, is at last beginning to give us an insight into the *how* of this problem—but only by building on the Mendelian foundation which Prof. Johnstone scorns. I would refer critics to Goldschmidt's new book ("Physiologische Theorie der Vererbung") and to a brief critical summary of my own (NATURE, Feb. 23, 1924) as showing how the obvious difficulties of the situation may perhaps be surmounted. I hope to summarise some of the recent work on the relations of hereditary constitution to developmental physiology in an article in NATURE in the near future. Meanwhile I would merely ask Prof. Johnstone whether he, like Prof. Noël Paton, wants to leave on one side all the results of Mendelian work in our attack upon the problem of heredity and its relation to the development of the organism as a whole? That is the only meaning I can attach to his concluding sentences; and it appears to me to be a counsel of despair.

Prof. Walker says (NATURE, Jan. 29, p. 161) that Dobell 'proved' that hereditary characters could not be controlled by chromosomes in certain Protozoa. The main reason advanced by Dobell concerned sex, and was that the Protozoa in question were haploid during all their sexually differentiated phase. If Prof. Walker had been better acquainted with genetical literature he would have remembered that almost simultaneously with Dobell's 'proof,' Wettstein was demonstrating experimentally, and conclusively, the control of sex by chromosomes in another group of organisms in which sex is displayed in the haploid phase—the mosses. Dobell's *a priori* arguments were never even theoretically valid, and long since fell to the ground on confrontation with actual fact.

As to Tornier:—If Prof. MacBride chooses to believe that experiments on developmental physiology, unaccompanied by breeding, have any direct bearing on heredity, I fear I cannot argue with him; to my mind, Tornier's work has just as much (or as little) bearing on the origin of mutations as has that of Driesch or Jenkinson or Child. For the information of readers of NATURE, however, it should be recorded that Berndt (*Zts. Ind. Abst. Vererb.*, 36, 1925) has repeated Tornier's goldfish work, and has also bred goldfish, on a large scale, and fails to verify either Tornier's facts or conclusions save in a few negligible details.

JULIAN S. HUXLEY.

King's College,
Strand, London, W.C.2, Feb. 22.

The Radcliffe Science Library, Oxford.

THE two paragraphs on pages 247-8 of NATURE of Feb. 12, 1927, in reference to the proposed transfer of the Radcliffe Science Library at Oxford to the University of Oxford, have been framed in such a way as to convey a false impression of the facts of the proposed arrangement. The Radcliffe Trustees would therefore be obliged if the following corrections could be inserted:

1. The trustees and the electors have refrained from appointing a successor to the late Dr. Jackson simply in view of the fact that very shortly after his death, negotiations for the proposed transfer were set on foot, pending which it would have been undesirable to make any fresh appointment.

2. In fact, the Library has been during the last few years most admirably carried on by the sub-librarian, Mr. James Ford, whose services the University has recently recognised by conferring on him the degree of M.A., *honoris causa*.

3. The second paragraph is a travesty of what is proposed. Had the writer, or the person who furnished the materials, candidly examined the print of the scheme of transfer which appeared in two numbers of the *Oxford University Gazette* (Feb. 2 and 9, 1927), he must have observed that all existing facilities and privileges of readers and students in the Radcliffe Science Library are preserved with meticulous care, including in particular 'the open shelf' and the right of taking books out into the various scientific departments of the University Museum.

4. In regard to the suggestions which both paragraphs make, that during these three years "the Library has lost many books by theft" (an inevitable source of loss which is in some degree common to all public libraries), the plain fact is that the annual proportion of such losses has fallen very much during the period in question: such books as have been so lost are current text-books of small pecuniary value, and their actual number is exceedingly small.

Cottesloe.
(Chairman of the Radcliffe Trustees.)

---

1. Lord Cottesloe does not explain why the Radcliffe Trustees, in negotiating the transfer of scientific books to the University, would not have been greatly assisted if they had had the benefit of the inside scientific knowledge of their own Librarian. Their readers have been deprived of his expert aid for *three* years, and that is a long time in the history of a science library, or in the life of an undergraduate.

2. The merits of Mr. Ford and his invariable courtesy on trying occasions are recognised by all who use the Library; but he would be the last person to lay claim to that special knowledge of scientific literature for which generations of Radcliffe Librarians have been famous and helpful.

3. The past success of the Science Library has undoubtedly been partly due to the above-mentioned facilities, wisely given by former Librarians. It is exceedingly doubtful whether the proposed association with the Bodleian Library will lead to the improvement of those facilities. The experience of many a reader is that the difficulties of obtaining books from the Bodleian for use in the Radcliffe Library are so great as to be deterrent.

4. Complaints of undergraduates who, on the eve of examination, are deprived of text-books, even though "of small pecuniary value," evidently ring louder in the ears of their tutors than in those of the Radcliffe Trustees.

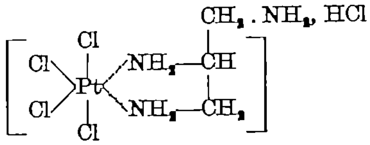
The Writer of the Notes.

A Novel Type of Optically Active Complex Metallic Salt.

Werner's conception of co-ordinated groups and of auxiliary valency has been extraordinarily useful in classifying and in elucidating the configurations of complex metallic compounds. Although many salts of this class, such as *tris*-ethylenediamine cobaltic chloride $[Co(NH_2.CH_2.CH_2.NH_2)_3]Cl_3$, have been resolved into optically active components, no proof has hitherto been given that an auxiliary valency linking can render a carbon atom asymmetric. This interesting proposition has been now established by the further study of the recently described salt, tetrachloro- (triaminopropane monohydrochloride)-platinum, $PtCl_4,NH_2.CH_2.CH(NH_2).CH_2.NH_2,HCl$, obtained by the action of the $\alpha\beta\gamma$-triaminopropane hydrochloride on chloroplatinic acid (Mann, *Jour. Chem. Soc.*, 129, 2681; 1926).

In the new salt the components, $PtCl_4$ and two of the NH_2-groups with some of the associated carbon and hydrogen atoms, must lie inside the co-ordinated group, whilst the third NH_2-group must protrude therefrom. It has now been found that the salt can be resolved into optically active components by the aid of silver *d*- and *l*-camphorsulphonate. The two salts, *l*-base *d*-acid, and *d*-base *l*-acid, have thus been obtained in an optically pure state; the hydrochlorides regenerated from these salts give molecular rotations of − 502° and + 501° respectively for the mercury green line in aqueous solution at 15°.

It is clear, therefore, that the constitution of the hydrochlorides must be represented by the following formula:



In the above formula the enantiomorphism of configuration is associated with asymmetry of the middle or β-carbon atom of the triaminopropane molecule; this asymmetry arises from the attachment of the α- and β-amino-groups to the platinum atom by auxiliary valencies. This is the first case to be recorded in which asymmetry of a carbon atom results from the operation of auxiliary valencies.

The new type of molecular enantiomorphism now disclosed will no doubt appear among numerous complex metallic compounds and, indeed, a complex copper salt, analogous in constitution to the above platinum salt, has been already prepared (*loc. cit.*). We are now engaged on the further investigation of these and other related compounds.

Migration and Reproductive Rhythm in Birds.

In a previous letter (Nature, April 4, 1925) a brief account was given of an attempt to break the annual reproductive rhythm in the Junco (*Junco hyemalis*) and to induce premature recrudescence of the gonads in the middle of the winter. It was suggested that migration might be dependent on the production of a hormone by the organs whilst in a certain stage of regeneration. Thanks to a research grant from the Royal Society, I have this winter been able to repeat and extend my earlier investigations. Nearly two hundred Juncos were trapped on their southward migration in the autumn and divided, as before, between two aviaries. The experimental one has been artificially lit since Oct. 1, beginning on the first day with 5 minutes after darkness, 10 on the second, 15 on the third, and so on. The controls got no artificial light. Their day was therefore decreasing, while that of the experimentals was increasing artificially at about the same rate as it would have been normally in the spring. Neither aviary is heated.

An experimental Junco was killed along with a control on Dec. 30, 1926, and dissected. In this experimental bird the testes were large and conspicuous and practically in the spring breeding condition. In the control the testes were found to be quite minute. The birds have been exposed to the severest winter weather on record in northern Alberta for at least the last twelve years, involving long spells with below-zero temperatures with a minimum of −35° F. Two canaries (one control, one experimental) which lived with the Juncos under identical conditions and were killed at the end of November 1926, possessed testes in precisely the same condition as those of the Juncos referred to above.

Juncos have been released at intervals. Out of 51 controls liberated between November and March (in two winters), 48 have been retaken alive at the point of liberation. Of the three remaining, one was killed by a cat, one by a shrike, and the last by a blizzard. In other words, it is evident that, regardless of temperature, barometric pressure, weather conditions in general, etc., birds released with their gonads at their resting minimum, stay where they are even though given their freedom hundreds of miles north of their normal wintering grounds. They will not migrate while in this condition.

Out of 36 experimentals released this winter after the first samples, taken at random from the aviary, showed the organs to be developing, 14 have been retaken. The other 22 departed upon release. All the ones retaken have been killed for examination. Without exception their gonads have been in the condition of one or other of the two Juncos referred to above. None with organs in an intermediate stage of development have stayed here upon release. Returns from liberated birds would probably be too much to hope for in the circumstances, but each is ringed with a U.S. Biological Survey band.

Carbon Monoxide Poisoning in the Absence of Hæmoglobin.

Warburg (*Biochem. Zeit.*, 177, p. 471; 1926) has shown that carbon monoxide depresses the rate of oxygen consumption by yeasts and a micrococcus, and that the amount of carbon monoxide required to produce a given effect increases with the partial pressure of oxygen. He concluded that carbon monoxide competes with oxygen for a catalyst concerned in respiration, as it does for hæmoglobin in vertebrates. He also showed that the affinity of oxygen for this substance is 7-14 times that of carbon monoxide, instead of 1/150 to 1/550 as in the case of hæmoglobin at 15° C., and that, like carbon monoxide hæmoglobin, the compound formed with carbon monoxide is dissociated by light.

I have extended these observations to two higher organisms, namely, the wax-moth *Galleria mellonella* and the cress plant *Lepidium sativum*. The moths behave normally in so little as 2·0 per cent. oxygen at atmospheric pressure provided this gas is diluted with 'nitrogen,' but become motionless in 0·8 per cent. In intermediate concentrations they are feeble and ataxic. When, however, the oxygen is diluted with carbon monoxide, about 16 per cent. of an atmosphere of oxygen is needed for normal behaviour, and in 8·8 per cent. oxygen + 91 per cent. carbon monoxide they are completely immobile. With intermediate amounts of oxygen, smaller amounts of carbon monoxide are poisonous. On admitting air, recovery is rapid and complete.

Cress seeds would not germinate at all in atmospheres containing less than 1·7 per cent. oxygen when diluted with nitrogen, and even in 5 per cent. oxygen growth was poor, though it was almost normal in 10 per cent. When the oxygen was diluted with carbon monoxide there was no germination whatever under 3 per cent. oxygen, and only a few seeds opened in 7 per cent., while in 14 per cent. growth was slow. A comparison of different cultures showed that for a given amount of growth 2-3 times as much oxygen was needed in the presence of large quantities of carbon monoxide as in its absence. Carbon monoxide is therefore relatively less poisonous for cress than for moths or yeast.

The most probable conclusion from these experiments is that oxygen, before it can be utilised for some at least of the oxidative processes in the cell, must combine with a substance possessing a lesser but well-marked affinity for carbon monoxide, these two gases combining with the same group in its molecule. As this substance is found in higher animals and plants as well as bacteria and fungi, it is probably a nearly universal cell constituent. The apparently different ratio of its affinities for carbon monoxide and oxygen in cress as compared with yeast and moths, is of course paralleled in the case of hæmoglobins from different animals.

Persistent Lines of Hafnium.

A number of spectra of zirconium ores and oxides have been examined for persistent lines of hafnium, using the wave-lengths for this latter element given by Hansen and Werner (Nature, 112, 618; 1923). The most persistent lines observed—three of which were found in all spectra examined—are at wave-lengths

2773·40, 2866·35, and 2919·55 angstroms,

of which the first is the most persistent. Other lines slightly less persistent are 2516·85, 2887·15, 2898·25, 2904·40, (2904·80), 2940·80, 2964·85, 3194·20. (The line 2904·80 is uncertain on account of a strong zirconium line nearby. The hafnium line and its neighbour 2904·40 are possibly a pair like those at 2513·00 and 2512·70. The line 2904·40 is very persistent, but the shorter pair are not.)

On account of the shortness of the range of Hansen and Werner's wave-lengths, none of these lines may safely be considered to be true *raies ultimes*, but their persistence may have some practical utility. In this regard it may be remarked that the crude ores are but slightly more difficult of examination than are fairly pure oxides, in spite of the richness of the preponderant spectra involved. With moderate dispersion ($\lambda\lambda$ 7000-2100 on a 10-inch plate) and good focus, the number of blends involving strong hafnium lines in the region studied is small and for analytical purposes probably of little moment. In using the ores and oxides of zirconium in a carbon arc, satisfactory spectra were not frequently obtained unless the arc carried enough current to be noisy. When satisfactory zirconium spectra were got there was no uncertainty about the hafnium traces, repeated exposures giving concordant results. Of the ores at hand the richest was of Wisconsin origin, being surpassed only by concentrates from a Carolina ore which was not available in crude state. In addition to the commoner elements in the ores, scandium appeared strongly in several cases.

Regularities in the spectrum of hafnium, to which the persistent lines should be a guide, have not yet appeared satisfactorily. The arc spectrum should be of odd multiplicity; McLennan, McLay, and Smith (*Proc. Roy. Soc. London*, 112, 76; 1926), applying Hund's principles, make the lowest arc term a triplet *F*. Inspection of Hansen and Werner's wave numbers beginning with the differences between the most persistent observed lines reveals a number of apparent triplets, and several triplet combinations having satisfactory intensities and the latter meeting possible inner quantum restrictions. Lacking confirmation such as Zeeman effect, these regularities seem, however, too conjectural to deserve recording at present.

The Intrinsic Fields in Ferromagnetic Substances.

From many points of view it seems evident that the so-called 'molecular field' introduced by P. Weiss into the theory of ferromagnetism cannot be purely magnetic. The magnitude of such a field, if responsible for the ferromagnetic phenomena, would be of the order of 10^7 gauss (in the saturated state). On the other hand, a purely magnetic field of the same order of magnitude, as W. Voigt has pointed out, is required for accounting for the enormous Faraday- or Kerr-effect in ferromagnetic substances. The study of this effect in the infra-red part of the spectrum (where the classical theory of 'free' electrons in metals is fairly valid) seems to make it probable that the so-called 'free' electrons moving between the atoms of iron or nickel are influenced by intrinsic magnetic fields of the order of 10^7 gauss. Thus two independent sources seem to make probable the existence of such enormous magnetic fields. Since both methods are, however, more or less indirect, it seemed worth while to work out a direct experimental method which could give some information as to the fields existing inside a ferromagnetic substance.

As an instrument for studying the intrinsic fields, a narrow beam of real free electrons, β-particles, was chosen. If a magnetic field exists inside a magnetised foil of nickel, it is evident that the beam of β-particles passing through the foil will be deflected. The experimental arrangement was chosen in such a way that fields of the order of 10^4 gauss (that is, fields of the order of the induction actually existing) would remain unnoticed. But fields exceeding 10^5 gauss could be easily detected by the displacement of the traces of β-particles on a photographic plate. Nickel-foils of 0·015 mm.–0·022 mm. thickness were magnetised in fields of about 500 gauss and more.

No difference whatever was detected between photographs taken using magnetised and demagnetised nickel foil. Thus it can be claimed that no magnetic field exceeding 10^5 gauss exists in a ferromagnetic substance.

Further experiments on the passage and scattering of β-particles in ferromagnetic substances are in progress.

Action of Magnetic Fields on the Refractive Index of Carbon Dioxide Gas.

In Nature of Nov. 20, 1926, p. 734, Messrs. Ghosh and Mahanti report an alteration of refractive index of carbon dioxide on applying a magnetic field of 3600 gauss transversely to the direction of propagation of the light. They attempt to explain this effect by an orientation of the molecules in the magnetic field. Now in a gas the molecules of which are orientated, if any effect on the refractive index were expected, one would naturally anticipate the primary effect would be a double refraction. Krishnan (*Proceedings of the Indian Association for the Cultivation of Science*, 10, 1. 35; 1926) has searched diligently for this effect in pure carbon dioxide over the whole range of pressures used by Ghosh and Mahanti, and his results were uniformly negative. For this reason an effect of the type described could not be due to molecular orientation. Further, the basis for the supposition of orientation in polyatomic gases, namely, the experiments of Glaser on their susceptibility, has been rendered very uncertain by Lehrer (*Ann. d. Physik*, 81, 229; 1926). Using a more satisfactory method, the latter was unable to reproduce Glaser's results. These facts made the experiments of Ghosh and Mahanti very difficult to understand, and it was considered worth while to repeat them.

Fields of 3600 and 6000 gauss were used. The carbon dioxide was prepared by heating pure sodium bicarbonate, and was dried by freezing and over phosphorus pentoxide. A Jamin refractometer was used, illuminated by the green line of mercury, $\lambda = 5461$. The compensating tube was evacuated; the other lay between the poles of an electromagnet. Carbon dioxide was admitted by a leak into the second tube, and at the same time the fringe shift was noted. In all sixty fringes passed the cross-wire for the range of pressure, 0-450 mm. mercury, as opposed to eight in the experiment of Ghosh and Mahanti. On plotting pressure against fringe-shift the same straight line was obtained whether the field was on or off, and on reduction the refractivity agreed to within one-half per cent. with the tabulated value. In fact, the results seem quite inconsistent with the parabolic curve of Ghosh and Mahanti.

Cavendish Laboratory, Cambridge.

Magnetic Induction in Continuous Media.

Consider a volume τ of any shape, occupied by material of unit permeability, having resistivity ρ (e.m.u.) placed in an alternating magnetic field of arbitrary distribution, sinusoidal in time, with pulsatance p. Let L specify its leading dimension. The three parameters which, together with the applied field distribution, determine the heat generated and the power dynamically conserved in the volume τ, are L, ρ, p. Then if H (e.m.u.) denotes the amplitude of the magnetic field at a particular point, the heat generated can be written

$$H^2 . L^\alpha p^\beta \rho^\gamma f\left(\frac{L^2 p}{\rho}\right) \text{ erg./sec.}^{-1},$$

where the function f depends, *inter alia*, on the distribution of H. It is supposed that the greatest dimension of the volume τ is short compared with $\frac{2\pi c}{p}$.

The argument of f is in effect the only possible adimensional combination of the parameters.

Then $L^\alpha p^\beta \rho^\gamma$ must have dimensions $L^3 T^{-1}$, and may therefore be written $L\rho(L^2 p/\rho)^\beta$ where β is arbitrary. If then we vary any two of the parameters, so as to keep $L^2 p/\rho$ constant, the power dissipated will vary as $L\rho$, $L^2 p$, $\rho\sqrt{\rho/p}$ according to the variables chosen, while for a complete variation, subject only to the above restriction, the power remains proportional to $L^2\sqrt{\rho p}$.

Variation of L has been supposed to take place by a variation of the scale of the space of τ and the field H. Variation of the power dynamically conserved obviously follows the same rules as the power dissipated.

Apparently this principle of similitude has not previously been formally enunciated.

Physical Aspects of Quantum Mechanics.[1]

By Prof. M. BORN, University of Göttingen.

THE purpose of this communication is not to give a report on the present status of quantum mechanics. Such a report has recently been published by W. Heisenberg, the founder of the new theory (*Die Naturwissenschaften*, **45**, 989, 1926). Here we shall make an attempt to understand the physical significance of the quantum theoretical formulæ.

At present we have a surprisingly serviceable and adaptable apparatus for the solution of quantum theoretical problems. We must insist here that the different formulations, the matrix theory, Dirac's non-commutative algebra, Schrödinger's partial differential equations, are mathematically equivalent to each other, and form, as a whole, a single theory. This theory enables us to compute the stationary states of atoms and the corresponding radiation, if we neglect the reaction of the radiation on the atoms; it would seem that in this respect we have nothing more to wish for, since the result of every example in which the calculations are carried out agrees with experiment.

This question, however, of the possible states of matter does not exhaust the field of physical problems. Perhaps more important still is the question of the course of the phenomena that occurs when equilibrium is disturbed. Classical physics was entirely concerned with this question, as it was almost powerless toward the problem of structure. Conversely, the question of the course of phenomena had practically disappeared from the quantum mechanics, because it did not immediately fit into the formal developments of the theory. Here we shall consider some attempts to treat this problem on the new mechanics.

In classical dynamics the knowledge of the state of a closed system (the position and velocity of all its particles) at any instant determines unambiguously the future motion of the system; that is the form that the principle of causality takes in physics. Mathematically, this is expressed by the fact that physical quantities satisfy differential equations of a certain type. But besides these causal laws, classical physics always made use of certain statistical considerations. As a matter of fact, the occurrence of probabilities was justified by the fact that the initial state was never exactly known; so long as this was the case, statistical methods might be, more or less provisionally, adopted.

The elementary theory of probability starts with the assumption that one may with reason consider certain cases equally probable, and derives from this the probability of complicated combinations of these. More generally: starting with an assumed distribution (for example, a uniform one, with equally probable cases) a dependent distribution is derived. The case in which the derived distribution is entirely or partly independent of the assumed initial distribution is naturally particularly important.

The physical procedure corresponds to this: we make an assumption about the initial distribution, if possible, one about equally probable cases, and we then try to show that our initial distribution is irrelevant for the final, observable, results. We see both parts of this procedure in statistical mechanics: we divide the phase space into equally probable cells, guided only by certain general theorems (conservation of energy, Liouville's theorem); at the same time we try to translate the resulting space-distribution into a distribution in *time*. But the ergodic hypothesis, which was to effect this translation, and states that every system if left to itself covers in time its phase space uniformly, is a pure hypothesis and is likely to remain one. It thus seems that the justification of the choice of equally probable cases by dividing the phase space into cells can only be derived *a posteriori* from its success in explaining the observed phenomena.

We have a similar situation in all cases where considerations of probability are used in physics. Let us take as an example an atomic collision—the collision of an electron with an atom. If the kinetic energy of the electron is less than the first excitation potential of the atom the collision is elastic: the electron loses no energy. We can then ask in what direction the electron is deflected by the collision. The classical theory regards each such collision as causally determined. If one knew the exact position and velocity of all the electrons in the atom and of the colliding electron, one could compute the deflexion in advance. But unfortunately we again lack this information about the details of the system; we have again to be satisfied with averages. It is usually forgotten that in order to obtain these, we have to make an assumption about equally probable configurations. This we do in the most 'natural' way by expressing the co-ordinates of the electron in its initial path (relative to the nucleus) in terms of angle variables and phases, and by treating equal phase intervals as equally probable. But this is only an assumption, and can only be justified by its results.

The peculiarity of this procedure is that the microscopic co-ordinates are only introduced to keep the individual phenomena at least theoretically determinate. For practical purposes they do not exist: the experimentalist only counts the number of particles deflected through a given angle, without bothering about the details of the path; the essential part of the path, in which the reaction of the atom on the electron occurs, is not open to observation. But from such numerical data we can draw conclusions about the mechanism of the collision. A famous example of this is the work of Rutherford on the dispersion of α-particles; here, however, the microscopic co-ordinates are not electronic phases, but the distance of the nucleus from the original path of the α-particle. From the statistics of the dispersion; Rutherford could prove the validity of Coulomb's law for the reaction between the nucleus and the α-particle. The microscopic co-ordinate had been eliminated from the theoretical formula for the distribution of the particles over different angles of deflexion.

---

[1] Extension of a paper read before Section A (Mathematics and Physics) of the British Association at Oxford on Aug 10, 1926. Translated by Mr. Robert Oppenheimer. The author is very much obliged to Mr. Oppenheimer for his careful translation.

We thus have an example of the evaluation of a field of force by counting, by statistical methods, and not by the measurement of an acceleration and Newton's second law.

This method is fundamentally like that which makes us suspect that a die is false if one face keeps turning up much more often than every sixth throw; statistical considerations indicate a torque. Another example of this is the 'barometer formula.' Of course, we can derive this dynamically, if we regard the air as a continuum and require equilibrium between hydro-dynamical pressure and gravity; but actually pressure is only defined statistically as the average transport of momentum in the collisions of the molecules, and it is therefore not merely permissible but also fundamentally more sound to regard the barometer formula as a counting of the molecules in a gravitational field, from which the laws of the field may be derived.

These considerations were to lead us to the idea that we could replace the Newtonian definition of force by a statistical one. Just as in classical mechanics we concluded that there was no external force acting if the motion of the particle was rectilinear, so here we should do so if an assembly of particles was uniformly distributed over a range. (The choice of suitable co-ordinates leads to similar problems on both theories.) The magnitude of a force, classically measured by the acceleration of a particle, would here be measured by the inhomogeneity of an assembly of particles.

In the classical theory we are of course faced with the problem of reducing the two definitions of force to one, and that is the object of all attempts at a rational foundation of statistical mechanics; we have tried to make clear, though, that these have not been altogether successful, because in the end the choice of equally probable cases cannot be avoided.

With this preparation we turn our attention to quantum mechanics. It is notable that here, even historically, the concept of *a priori* probability has played a part that could not be thrown back on equally probable cases, for example, in the transition-probabilities for emission. Of course this might be merely a weakness of the theory.

It is more important that formal quantum mechanics obviously provides no means for the determination of the position of particles in space and time. One might object that according to Schrödinger a particle cannot have any sharply defined position, since it is only a group of waves with vague limits; but I should like to leave aside this notion of 'wave-packets,' which has not, and probably cannot be, carried through. For Schrödinger's waves move not in ordinary space but in configuration space, that has as many dimensions as the degrees of freedom of the system ($3N$ for N particles). The quantum theoretical description of the system contains certain declarations about the energy, the momenta, the angular momenta of the system; but it does not answer, or at least only answers in the limiting case of classical mechanics, the question of where a certain particle is at a given time. In this respect the quantum theory is in agreement with the experimentalists, for whom microscopic co-ordinates are also out of reach, and who therefore only count instances and indulge in statistics. This suggests that quantum mechanics similarly only answers properly put statistical questions, and says nothing about the course of individual phenomena. It would then be a singular fusion of mechanics and statistics.

According to this, we should have to connect with the wave-equations such a picture as this: the waves satisfying this equation do not represent the motion of particles of matter at all; they only determine the possible motions, or rather states, of the matter. Matter can always be visualised as consisting of point masses (electrons, protons), but in many cases the particles are not to be identified as individuals, *e.g.* when these form an atomic system. Such an atomic system has a discrete set of states; but it also has a continuous range of them, and these have the remarkable property that in them a disturbance is propagated along a path away from the atom, and with finite velocity, just as if a particle were being thrown out. This fact justifies, even demands, the existence of particles, although this cannot, in some cases as we have said, be taken too literally. There are electromagnetic forces between these particles (we neglect for the moment the finite velocity of propagation); they are, so far as we know, given by classical electrodynamics in terms of the positions of the particles (for example, a Coulomb attraction). But these forces do not, as they did classically, cause accelerations of the particles; they have no direct bearing on the motion of the particles. As intermediary there is the wave field: the forces determine the vibrations of a certain function ψ that depends on the positions of all the particles (a function in configuration space), and determine them because the coefficients of the differential equation for ψ involve the forces themselves.

A knowledge of ψ enables us to follow the course of a physical process in so far as it is quantum mechanically determinate: not in a causal sense, but in a statistical one. Every process consists of elementary processes, which we are accustomed to call transitions or jumps; the jump itself seems to defy all attempts to visualise it, and only its result can be ascertained. This result is, that after the jump, the system is in a different quantum state. The function ψ determines these transitions in the following way: every state of the system corresponds to a particular characteristic solution, an ***Eigenfunktion***, of the differential equation; for example, the normal state the function ψ_1, the next state ψ_2, etc. For simplicity we assume that the system was originally in the normal state; after the occurrence of an elementary process the solution has been transformed into one of the form

$$\psi = c_1 \psi_1 + c_2 \psi_2 + c_3 \psi_3 \ldots ,$$

which represents a superposition of a number of ***eigenfunktions*** with definite amplitudes c_1, c_2, c_3, . . . Then the squares of the amplitudes c_1^2, c_2^2 . . . , give the probability that after the jump the system is in the 1, 2, 3, state. Thus c_1^2 is the probability that in spite of the perturbation the system remains in the normal state, c_2^2 the probability that it has jumped to the second, and so on.[2] These probabilities are thus dynamically determined. But what the system actually does is not determined, at least not by the laws that are at present known. But this is nothing new, for we saw above that the classical theory—for example, for the collision problem—only gave probabilities. The classical theory introduces the microscopic co-ordinates which determine the individual process, only to eliminate them because of ignorance by averaging over their values; whereas the new theory gets the same results without introducing them at all. Of course, it is not forbidden to believe in the existence of these co-ordinates; but they will only be of physical significance when methods have been devised for their experimental observation.

This is not the place to consider the associated philosophical problems; we shall only sketch the point of view which is forced upon us by the whole of physical evidence. We free forces of their classical duty of determining directly the motion of particles and allow them instead to determine the probability of states. Whereas before it was our purpose to make these two definitions of force equivalent, this problem has now no longer, strictly speaking, any sense. The only question is why the classical definition is so useful for a large class of phenomena. As always in such cases, the answer is: Because the classical theory is a limiting case of the new one. Actually, it is usually the 'adiabatic' case with which we have to do: *i.e.* the limiting case where the external force (or the reaction of the parts of the system on each other) acts very slowly. In this case, to a very high approximation

$$c_1^2 = 1,\ c_2^2 = 0,\ c_3^2 = 0 \ldots ,$$

that is, there is no probability for a transition, and the system is in the initial state again after the cessation of the perturbation. Such a slow perturbation is therefore reversible, as it is classically. One can extend this to the case where the final system is really under different conditions from the initial one; *i.e.* where the state has changed adiabatically, without transition. That is the limiting case with which classical mechanics is concerned.

It is, of course, still an open question whether these conceptions can in all cases be preserved. The problem of collisions was with their help given a quantum mechanical formulation; and the result is qualitatively in full agreement with experiment. We have here a precise interpretation of just those observations which may be regarded as the most immediate proof of the quantised structure of energy, namely, the critical potentials, that were first observed by Franck and Hertz. This abrupt occurrence of excited states with increasing electronic velocity of the colliding electron follows directly out of the theory. The theory, moreover, yields general formulæ for the distribution of electrons over the different angles of deflexion, that differ in a characteristic way from the results that we should have expected classically. This was first pointed out by W. Elsasser (*Die Naturwissenschaften*, **13**, 711, 1925) before the development of the general theory. He started with de Broglie's idea that the motion of particles is accompanied by waves, the frequency and wave-length of which is determined by the energy and momentum of the particle. Elsasser computed the wave-length for slow electrons, and found it to be of the order of 10^{-8} cm., which is just the range of atomic diameters. From this he concluded that the collision of an electron with an atom should give rise to a diffraction of the de Broglie waves, rather like that of light which is scattered by small particles. The fluctuation of the intensities in different directions would then represent the irregularities in the distribution of the deflected electrons. Indications of such an effect are given by the experiments of Davisson and Kunsmann (*Phys. Rev.*, **22**, 243, 1923), on the reflection of electrons from metallic surfaces. A complete verification of this radical hypothesis is furnished by Dymond's experiments on the collisions of electrons in helium (Nature, June 13, 1925, p. 910).

Unfortunately, the present state of quantum mechanics only allows a qualitative description of these phenomena; for a complete account of them the solution of the problem of the helium atom would be necessary. It therefore seems particularly important to explain the above-mentioned experiments of Rutherford and his co-workers on the dispersion of α-particles; for in this case we have to do with a simple and completely known mechanism, the 'diffraction' of two charged particles by each other. The classical formula which Rutherford derived from a consideration of the hyperbolic orbits of the particles, is experimentally verified for a large range; but recently Blackett has found departures from this law in the encounters between α-particles and light atoms, and has suggested that these might also be ascribed to diffraction effects of the de Broglie waves. At present only the preliminary question is settled, of whether the classical formula can be derived as a limiting case of quantum mechanics. G. Wentzel (*Zeit. f. Phys.*, **40**, 590, 1926) has shown that this is in fact the case. The author of this communication has, furthermore, carried through the computation for the collision of electrons on the hydrogen atom, and arrived at formulæ which represent simultaneously the collisions of particles of arbitrary energy (from slow electrons to fast α-particles). As yet this has only been carried out for the first approximation, and so gives no account of the more detailed diffraction effects. This calculation thus yields a single expression for the Rutherford deflexion formula and the cross section of the hydrogen atom for electrons in the range studied explicitly by Lenard. The same method leads to a calculation of the probability of excitation of the H-atom by electronic collision, but the calculations have not yet been completed.

---

[2] We may point out that this theory is not equivalent to that of Bohr, Kramers, Slater. In the latter the conservation of energy and momentum are purely statistical laws; on the quantum theory their exact validity follows from the fundamental equations. Statistical considerations only apply to quantities, like the angles of deflexion in a collision, which could not be quantised on the Bohr theory of angle variables.

It would be decisive for the theory if it should prove possible to carry the approximation further, and to see whether it furnishes an explanation of the departures from the Rutherford formula.

Even, however, if these conceptions stand the experimental test, it does not mean that they are in any sense final. Even now we can say that they depend too much on the usual notion of space and time. The formal quantum theory is much more flexible, and susceptible of much more general interpretations. It is possible, for example, to mix up co-ordinates and momenta by canonical transformations, and so to arrive at formally quite different systems, with quite different wave functions ψ. But the fundamental idea of waves of probability will probably persist in one form or another.[3]

---

Benedictus de Spinoza.

By Prof. G. DAWES HICKS.

FIFTY years ago a memorable gathering of distinguished men assembled at The Hague, under the presidency of Prince Alexander of the Netherlands, on the occasion of the two-hundredth anniversary of Spinoza's death. They met in a building which was only a few yards away from the house in the Paviljonensgracht where the philosopher had spent the last few years of his life, and where on Feb. 21, 1677, he died. The principal speaker at that gathering was Ernest Renan; and, having in mind the monument about to be erected, and referring to the humble dwelling hard by, Renan exclaimed: "From his granite pedestal Spinoza will teach us all to follow the way which he found to happiness, and, centuries hence, men of learning, crossing the Paviljonensgracht, will say to themselves, 'It is perhaps from this spot that God was most nearly seen.'" The statue was finished in 1880; and now, on the two-hundred-and-fiftieth anniversary of Spinoza's death, it is proposed to complete the memorial by acquiring the house, to be called the *Domus Spinozana*, and equipping it as a home for research and as a meeting-place for scientific workers of various nationalities. It will be a fitting tribute to one of the world's greatest minds.

The story of this lonely thinker's life has frequently been told. Born at Amsterdam, whither his father had migrated from Portugal about thirty years previously, on Nov. 24, 1632, he spent the whole of his days in Holland. His mother died when he was barely six years old, and his father when he was twenty-two. Two years after his father's death he was excommunicated by the Rabbis; and from that period onwards he lived in modest lodgings, supporting himself at first partly by teaching and partly by grinding lenses for spectacles and optical instruments, in which latter occupation he persevered to the end. Until 1660 he remained in Amsterdam, where he became the leading spirit of a small circle of friends, who after his departure met periodically to discuss philosophical papers which he sent to them. From 1660 until 1663 he resided in Rhynsberg, near Leyden, and there he wrote the "De Intellectus Emendatione," part of his exposition of Descartes' "Principia" with the appendix, "Cogitata Metaphysica," and perhaps a portion of the "Ethics." In 1663 he removed to Voorburg, near The Hague, and stayed there until 1670. At Voorburg he was at first occupied with the "Ethics," but laid it aside in order to devote himself to the "Tractatus Theologico-Politicus," which seemed to him to be the more urgently needed, and which was published anonymously in 1670. In 1670 he removed to The Hague, where he remained until his death in 1677. Here he finished the "Ethics" and wrote the unfinished "Tractatus Politicus," both of which were published in the "Opera Posthuma," that appeared before the end of the year 1677. Nearly two centuries later there was discovered and published the Dutch text of a work of Spinoza's which appears to have been called "Tractatus de Deo et homine ejusque felicitate," written about the year 1660.

At the beginning of the treatise "De Intellectus Emendatione," Spinoza relates the circumstances that led him to devote himself to philosophical inquiry. The ordinary objects of human pursuit —sensuous enjoyment, wealth, station—had all evinced themselves, even when attained, as incapable of yielding real and lasting happiness. The reason seemed to him to be due to the fact that, while these objects are invariably transitory and fleeting in character, in making them ultimate ends men take them to be permanent and self-sufficing. True blessedness (*beatitudo*) could come only from being in possession of a changeless and abiding object of love, and there is, he was assured, no way of obtaining that possession save by knowing things as they actually are. For it was because in everyday experience our apprehension of things is fragmentary and piecemeal, because we contemplate them in isolation and from a limited point of view, that we are misled into desiring some of them as though they could constitute for us the supreme ends of life.

Scientific knowledge would, on the other hand, reveal the interconnexion of finite events, their dependence upon each other, and upon reality as a whole. The Whole alone could be perfect and eternal; and love of it could alone satisfy the soul's yearning. But the soul can only love what it knows; in order to be in harmony with the Whole, the mind of man must gain a more or less clear insight into its nature. To have a conception of the Whole would amount to having a conception of the eternal and necessary order of the universe; and, since "we needs must love the highest when we see it," would mean the attainment, on our part, of full and complete satisfaction of desire. It was, then, because he was convinced that knowledge is the way to blessedness, that Spinoza set forth upon the intellectual quest, and did not touch the problems of ethics until he had first sought to unravel the general structure of reality.

Spinoza's philosophy takes its start from the fundamental distinction between 'substantial' or self-dependent being and 'modal' or dependent being,—the distinction, in other words, between that which is 'in itself' (*in se*) and is conceived 'through itself' (*per se*) and that which is 'in another' (*in alio*) and is conceived through that other (*per quod etiam*). It had been, indeed, a cardinal principle of the Aristotelian philosophy that what Aristotle called primary substance was marked off from other kinds of being in virtue of the fact that in a proposition it could only stand as the subject, and never as the predicate, or as the quality of anything else. But, in Aristotle's view, finite individual entities were substances in this sense, whereas Spinoza's contention is that, when we have regard to its antecedents, there is no finite individual entity that does not forfeit its supposed substantive character and turn out to be itself predicable as a phase or modification of something else. Consequently, there can be but one self-dependent Being or Substance, namely, Reality, in its absolute entirety and completeness. What we take to be independent, substantive entities, whether physical or mental, must ultimately evince themselves as derivative 'modes' or states of the one absolute Being, ways in which that one absolute Being expresses or manifests itself.

The originality of Spinoza's thought comes strikingly to light in his determined and resolute effort to work out this conception. Substance, as that which is self-dependent, as *causa sui*, or the Unconditioned, must, he argued, be conceived as necessarily existing; in regard to it, that is to say, the question of origin or genesis cannot be raised. The existence of one finite event may legitimately enough be accounted for as the effect of another finite event, and that again as the effect of another, and so on in a never-ending series. But Substance is not an event, not even one colossal event, overlapping all others. It is that which must be presupposed in order that happenings or events should be at all. There can only be a coming-to-be *within* the realm of being. Accordingly, whoever admits the existence of any event, even that of his own act of thinking, is bound to admit the existence of that without which the existence of events would be inconceivable; and, since coming to be and ceasing to be form no part of the content of the Self-existent, this means that Substance must be 'eternal,' *i.e.* timeless, in character, that the Self-existent must be regarded as an eternal truth, which cannot be explained in terms of time or duration, even though that duration be thought of as unbounded in both directions.

Further, from the notion of the Self-existence there follows that of the infinitude of Substance. For as self-existent, Substance must, so Spinoza argues, be unique, and its uniqueness would be destroyed were it limited or restricted by other Self-existents. Just, however, as the term 'eternity' does not properly mean endless duration, so the term 'infinity' does not properly mean endless extent. Substance is infinite in the sense of being the self-contained, the self-complete; its infinity is involved, that is to say, in its unconditioned nature. So, too, Substance is one or a unity, not however in the numerical sense of being a member, even the single member, of a class, but in a sense in which ideas of number are inapplicable. Once more, Substance as complete, is perfection, yet again not in any sense that would imply the gradual realisation of a plan, the unfolding of something not yet actual, but in the sense that it is throughout all that it has in it to be.

Lastly, Substance is the cause of all things, and, indeed, ultimately the only cause. Still, the term 'cause' carries with it, in this context, no implication of producing or creating. To say that Substance is the cause of all things is to say that all things flow from the nature of Substance with the same timeless necessity as the equality of its three angles to two right angles follows from the nature of a triangle. By the term 'cause,' when used in reference to Substance, Spinoza understood, that is to say, logical ground or reason. As a logical ground involves its consequents, so the consequents of the supreme ground are not to be thought of as independent of it but as implicated essentially in it.

The supreme ground, thus conceived, is called by Spinoza indifferently 'Substance,' or 'Nature,' or 'God'; and by each of these terms he means simply Being in its fullness and completeness, that which comprises within its indivisible unity all the positive characteristics in which reality is expressed. What, in fact, he was concerned to maintain was that the notions which we apply legitimately enough to parts of the universe—notions of temporal sequence, change, producing cause, evolution, and so on—become unintelligible and meaningless when applied to the universe as a whole. To speak, for example, of 'cosmic evolution,' if by that be intended the evolution of the totality of things, is, he would have urged, a contradiction in terms. For evolution implies not only that which is evolving, but also an environment with which it is in interaction, and obviously there can be no environment of the totality of things. Not only so. Whoever pictures the universe in its entirety as evolving must inevitably be pulled up before the *impasse* of a first beginning. He would have to start with something, such, for example, as Herbert Spencer's 'indefinite, unstable homogeneity,' that 'once upon a time' appeared upon the stage of being. But, in that case, the philosophic problem centres precisely there; and so long as the 'something' remains unaccounted for, not a step has been taken towards the solution of that problem. Against all such ways of regarding the system of things, Spinoza insists upon conceiving it as an organic Whole, consisting of unconditioned and conditioned, of supreme ground and dependent consequents.

With this conception of God, or the Absolute, Spinoza had evidently left the somewhat halting conclusion of Descartes and the Cartesians a long way behind. It was no longer possible to ascribe to material things on one hand, and to minds on the other, the separate and independent existence which these thinkers had claimed for them. Material things and minds could be no other than 'modes,' phases, states (*affectiones*) of the one ultimate Reality. If, now, we proceed to inquire how the modes are related to one another and to Substance, we come upon the notion of 'Attribute,' concerning the significance of which much difference of opinion prevails. One interpretation, at any rate, it seems to me, merits unreserved rejection. Spinoza could not have meant that the Attributes are real forces or kinds of energy (*Urkräfte*, as Kuno Fischer has it) of which God or Substance is the bearer. For that would have been palpably inconsistent with wellnigh everything he had laid down with respect to the nature of Substance. What could one make, for example, of the 'eternity' of Substance (in which "there is no *when*, no *before*, and no *after*") were one to conceive of its essence as being constituted by potencies or powers of this description? And how, again, could the unity of Substance be retained, if its essence is to be thought of as made up of various kinds of energy—physical, mental, and possibly many others—operating along distinct, though parallel, lines of activity? If Substance be prior to and more universal than these streams of energy, then the latter would become, according to Spinoza's definitions, 'modes,' for each would have something in common with the others, and could not, therefore, be conceived through itself and in itself, in such a way that its conception did not involve the conception of anything else. If, on the other hand, Substance be not more universal than the Attributes, then, on the interpretation in question, it would inevitably resolve itself into a plurality of independent powers, which could only be externally connected.

No doubt any interpretation of Spinoza's meaning is exposed to criticism, but probably Sir Frederick Pollock's suggestion that the Attributes were intended to be taken as 'aspects' of Substance is most nearly in accord with the statement that "Attribute is what intellect apprehends of Substance as constituting its essence." As has often been pointed out, this statement implies by no means that the Attributes are merely our subjective ways of conceiving Substance. For that which is grasped by the 'intellect' (as contrasted with 'imagination') would be, according to Spinoza, objectively real. What, then, I take him to mean, is that there are not two realms, a realm of Extension and a realm of Consciousness, but that it is one and the same reality which manifests both aspects, that everything extended is at once also conscious, and everything conscious is at once also extended. All *res particulares* are, that is to say, regarded from one point of view, modes of Extension, and, regarded from another point of view, modes of Consciousness; all are, as he expresses it, *animata*, although in different degrees.

It is perfectly true that in tracing the descent from the Unconditioned to the Conditioned the idea of agency has at some stage to be introduced, and equally certain that then the crucial difficulties of Spinoza's philosophy are full upon us. Adopting a familiar device, Spinoza endeavoured to effect the passage from the infinite to the finite, from *Natura Naturans* (Nature as ground) to *Natura Naturata* (Nature as consequent, or as a system of modes), by inserting a number of intermediary terms in order to bridge the gap. He introduced, in fact, two grades or classes of what he called 'infinite modes'; first, those which follow immediately from the Attributes, and secondly, those which follow from the Attributes when already modified. On the side of Extension, motion and rest, on the side of Consciousness, the absolutely infinite intellect, are the immediate infinite modes, while the mediate infinite mode on the side of Extension is 'the form of the whole universe' (*facies totius universi*), that on the side of Consciousness not being named. Under cover of these intermediaries the element of activity enters full fledged upon the scene, though how it is supposed to emerge is veiled, it must be confessed, in obscurity. Motion follows, we are told, directly from extension. But does it? Motion may no doubt be said to depend upon extension, but in what sense can it be said to follow from it? If extension be extension simply, it cannot give rise to what is more than itself. Nor would the difficulty be surmounted by identifying extension with physical energy, for physical energy already involves motion, and there would be, in that case, no transition from Attribute to infinite mode.

The attempt not only to conceive an ultimate unity in which all determinate existents have their ground, but likewise to work out logically the conception, was, indeed, a tremendous undertaking, and Spinoza's philosophy will always stand as one of the most sustained efforts in the history of human thought to solve its deepest problem. No one would be concerned to claim that he actually accomplished the whole task which he prescribed for himself. Few would now, I take it, venture to dispute the judgment that in the long run the modal system and the supreme ground fail to come together in one coherent view, that the temporal existence of modes obstinately refuses to fit into the timeless being of Substance. On one hand, it is contended that all things which follow from the absolute nature of any Attribute of Substance must exist eternally and be infinite, and that that which is finite and has a determinate existence can not be produced by the absolute nature of any such Attribute. On the other hand, it is maintained that a determinate existent thing cannot be determined to exist or to act, unless it be so determined by another cause which is also finite and has a determinate existence, and so on *ad infinitum*. That is to say, a determinate existent thing has a positive reality in so far as it expresses the eternal essence of Substance, but in so far as it is finite, in so far as it is limited and restricted, it has not. Yet it is precisely in this latter capacity that modes function as causes in the modal sphere, and thus serve to account for the existence of each other. Modal existence has to be recognised as a fact, though it falls apart from substantial existence, and the chasm widens as the character of the former comes to be more closely scrutinised. But criticism is comparatively easy, constructive thinking is difficult. When criticism has in this connexion said its last word, there will remain in Spinoza's constructive achievement amply sufficient to entitle him to the lasting gratitude of those who in his spirit strive to carry on the work of philosophical inquiry.

Obituary.

Mr. J. J. Lister, F.R.S.

With the death of J. J. Lister on Feb. 5 in his home at Grantchester, there passes away one of the band of younger zoologists who, under the leadership of Francis Maitland Balfour, helped to build up the reputation of the Cambridge school of zoology. Although he was most widely known for his important researches on the morphology and reproduction of the Foraminifera, he was a man of liberal interests in many branches of zoology and a keen and accomplished naturalist. Those of us who were his friends and colleagues in the 'eighties vividly remember not only his charm of manner but also the bright and stimulating conversation with which he enlivened our social meetings. There seemed to be few subjects within the wide range of natural history about which he had not something interesting to say. At the same time he was to the undergraduates of his generation a hero in the athletic world. As stroke of the first boat of the Lady Margaret Boat Club from 1878 until 1882, he led his men to many victories both on the Cam and at Henley, and later he was often seen on the river as stroke of the "Ancient Mariners."

Born at Leytonstone in 1857, Lister was the son of Mr. Arthur Lister, who was himself a fellow of the Royal Society and brother of Lord Lister. From an early period of his life, therefore, he must have been associated with men of scientific tastes and initiated into some of the mysteries of biological problems. His father was an authority on the Mycetozoa and published many important papers on this group of organisms. J. J. Lister and his sister took part in these investigations and added materially to the common stock of knowledge that the family possessed. It was not surprising, therefore, that when he wrote the article on Mycetozoa for Lankester's "Treatise on Zoology," it was rightly appraised as the most authoritative summary of our knowledge of the group in the language. But Lister was destined to achieve great personal fame for his work on another group of protozoa. The dimorphism of the species of Foraminifera was already known, but Lister showed, by the most careful investigations of the Polystomella of our own seas, that the two forms are not male and female respectively as had been suggested, but that each produces free swimming spores and that the spores of one of them may be sexual spores, although he failed to prove that the process of conjugation actually took place. His researches on Orbitolites, Quinqueloculina, Polytrema, and other Foraminifera also produced valuable additions to our knowledge of the group.

After taking his degree Lister entered St. Bartholomew's Hospital with the intention of entering the medical profession, but owing to ill-health he abandoned the idea and travelled for some years, first in a sailing ship to Australia and afterwards in H.M.S. *Egeria* in the Pacific Ocean. During this voyage in the surveying sloop, when he had the opportunity of visiting several remote and interesting islands, his ability as an accomplished man of science showed itself in the records of several important observations he made on various subjects. A short paper on the birds of Phœnix Island, in which he described the nesting habits of the frigate birds; an account of the natives of Bowditch Island; and the important conclusion he reached by his study of the islands of the Tonga Group, that, contrary to the Darwinian hypothesis of subsidence, coral reefs and atolls are formed in some regions where the land is undergoing elevation, were some of the varied contributions to knowledge that resulted.

Among the collections he brought home were some specimens of the coral Millepora beautifully preserved in spirit with the zooids expanded, and these he most generously handed over to the writer of this article for further study. They are undoubtedly the only specimens in which the expanded zooids have been seen in Great Britain, for in all the other material that has been collected the zooids are so tightly contracted as to be useless for demonstration purposes. He also brought back some specimens of the young stalked form of the coral Fungia, described by Stutchbury in 1830, and wrote a paper on the strobilisation of the genus.

During the later years of his life, long and continuous ill-health led to a retired life in his home in Grantchester, and his visits to the University Museum and Laboratory became more and more infrequent. But his interest in natural history never waned, and he devoted his energies to a searching investigation of variation in British Lepidoptera.

Lister was made a fellow of his College (St. John's) in 1899, and elected to the fellowship of the Royal Society in 1900. He was president of Section D of the British Association at the York meeting in 1906, and for many years an active member of the council of the Marine Biological Association.

S. J. H.

Prof. E. H. Rennie.

Dr. E. H. Rennie, whose death in South Australia was recently announced, was for more than forty years professor of chemistry in the University of Adelaide. Born on Aug. 19, 1852, he was the son of E. A. Rennie, Auditor-General of New South Wales, and grandson of James Rennie, who was professor of zoology at King's College, London, 1830–1834. His school days were spent in Sydney, and he graduated at the University of Sydney in 1870. For a few years he taught in the Sydney and Brisbane Grammar Schools, and in 1877 came to London to study chemistry. He obtained his doctor's degree in the University of London in 1881. While in London he was assistant for two years to Dr. C. R. Alder Wright in the Chemical Department of St. Mary's Hospital Medical School, and also taught occasionally in the Royal College of Science. On his return to Australia he found employment in the Government Analyst's Department in Sydney. In 1885 he was appointed Angus professor of chemistry in the University of Adelaide, in which capacity he rendered fine service.

Rennie's natural temperament and his upbringing gave him a strict view of his obligations, and he shrank from no labour that would enable him to fulfil them. It must be added that if he expected much from himself, he also expected that his students would do their full share. But his kindliness and sympathy tempered his sense of what was to be demanded from those whom he taught, and he was liked even as much as he was respected. His thorough knowledge of his subject and his sound training in the laboratory, with his capacity for clear expression and his wide outlook, made him an excellent teacher. Outside his own department he was devoted to the general work of the University, and he took a large share in the direction of its rapidly growing activities. He played a leading part in the institution of technical education in Adelaide, and was a warm supporter of the Australasian Association for the Advancement of Science. He also found time to do some research work, principally on the chemistry of Australian products.

Rennie was thoroughly happy when he was able to get away from his work to his boat and his fishing. His enjoyment on all such occasions was only matched by his disreputable appearance: many stories were told of his adventures by those who were invited to accompany him on his cheerful expeditions.

It was fortunate for the young University of Adelaide that its staff should include from early times and for so long a professor of such ability, integrity, good judgment, and tact. He set a fine standard at the moment when naturally it was most valuable; he was trusted by every one inside the University and out; and he helped materially to establish the University of Adelaide in a strong position and to build up its present good reputation.

Major J. R. Erskine Murray.

Major Murray was born in Edinburgh in 1868. At the University of Glasgow he studied under Lord Kelvin, and during the final years of his six years' course he did useful research work. He then entered Trinity College, Cambridge, as a research student. After being an assistant professor for two years at the Heriot-Watt College, Edinburgh, he was appointed an experimental assistant to Marconi. His interests now became centred in radio work. He acted as a demonstrator at University College, Nottingham, and as lecturer to the George Coats Technical College at Paisley. In 1907 he started consulting work in radio-telegraphy and gave lectures on it to Faraday House, London, and other colleges. In 1913 he became a partner in the firm of Messrs. Clarke, Forde, Taylor, and Erskine Murray, consulting engineers.

During the War Dr. Erskine Murray served with the Royal Air Force, being in charge of the radio instruments. He then became Experimental Engineer at H.M. Signal School, Royal Naval Barracks, Portsmouth.

Dr. Erskine Murray contributed several papers to various societies. Shortly after the War he gave to the Institution of Electrical Engineers a practical demonstration of communication by radio-telephony with an aeroplane in flight over London. His best-known book is a handbook on "Wireless Telegraphy," first published in 1907, which has gone through several editions, each edition having to be subjected to a thorough revision owing to the rapid progress of the art. He translated Ruhmer's "Wireless Telephony," to which he contributed a useful appendix. He also wrote a small but useful treatise on "Wireless Telephones and how they Work."

As an experimenter Erskine Murray's ability was of a high order. He took great pains in preparing experiments for his lectures, although he often used the very simplest apparatus. He had the gift of being able to communicate some of his enthusiasm to his students. His death after a very short illness has come as a great blow to his many friends.

We regret to announce the following deaths:

Mr. H. B. Goodwin, formerly examiner in nautical astronomy at the Royal Naval College, Greenwich, and the author of various works on this subject, on Feb. 24, aged seventy-nine years.

Mr. F. B. Guthrie, chemist in the Department of Agriculture, New South Wales, for some thirty years, and author of papers in Thorpe's "Dictionary of Applied Chemistry" and technical periodicals, on Feb. 7, aged sixty-five years.

Dr. Leopold Spiegel, extra-ordinary professor of the University of Berlin, who died suddenly on Jan. 8 at Charlottenburg in his sixty-second year. Prof. Spiegel, whose numerous investigations were chiefly upon alkaloids, was the discoverer of the drug yohimbin. He was also the author of several books on pharmacology, drugs, poisons, etc. For many years he was a member of the editorial board of the *Chemische Centralblatt.*

News and Views.

To-day is the centenary of the deaths of Volta and Laplace, who both died on Mar. 5, 1827, Volta being eighty-two years old and Laplace seventy-seven. Though in intellectual power Laplace was probably far superior to Volta, it may be that the electrical discoveries and inventions of Volta have had a greater effect upon the progress of civilisation than the profounder studies of Laplace. Each, however, in his own sphere did work which will cause his name to be recalled so long as science is studied. Volta's great contribution to science, the Voltaic pile, was made known in 1799, and that year also marked the publication of Laplace's immortal work "Mécanique Céleste."

Volta was born at Como in 1745 and came of a noble and ancient family. By 1774 he was holding a post in the Liceo at Como, and there, in the following year, he invented the electrophorus. Four years later he was appointed to the chair of physics in the University of Pavia. There were many students of electricity and magnetism during the eighteenth century, such as Gray, Canton, Dufay, Franklin, Nollet, Coulomb, Priestley, and Cavendish, and to these must be added Galvani, professor of anatomy at Bologna. Galvani for some years studied muscular contraction, especially in frogs, due to electric influence, but whereas Galvani attributed most of the effects obtained to animal electricity, Volta declared they could be traced to the contact of two metals in the presence of moisture. The landmarks in the history of the subject were Galvani's papers to the Bolognese Transactions in 1791, Volta's letters to Cavallo read to the Royal Society in 1793, and Volta's letter to Sir Joseph Banks read to the Royal Society in 1800. He had been awarded the Society's Copley medal in 1794, but it was in his letter of 1800 that Volta described the Voltaic pile and the "Couronne des Tasses." The new apparatus was early seized on by experimentalists, and the first Voltaic pile made in England was that of Nicholson and Carlisle, with which they decomposed water. In the hands of Davy the electric battery led to astonishing results, but these were all surpassed when Oersted for the first time discovered the influence of an electric current passing along a conductor on a magnetic needle, and thus founded the science of electromagnetism on which nearly all later developments have been based.

Laplace, less fortunate than Volta, came of poor parents and owed his education to wealthier neighbours. He was born at Beaumont-en Auge, Calvados, in 1749. Having taught mathematics for a while in his native place he went to Paris, enlisted the sympathies of D'Alembert, and found an instructor's place in the military school. Thence onward his progress was such that he was soon recognised as the rival of Lagrange. His memoirs of 1784 to 1789 on the motions of the moon, Jupiter, and Saturn are amongst the most important ever written. The Revolution found him an examiner to the artillery and a prominent member of the Paris Academy of Sciences and as such he did valuable work on the Commission of Weights and Measures. Though the academies were all suppressed in 1793, the fall of Robespierre was followed by the opening of the École Normale, the École Polytechnique, the National Institute, and the Bureau des Longitudes, in all of which Laplace took his place. His "Système du Monde" saw the light in 1796; the first part of the "Mécanique Céleste" in 1799. His famous nebular hypothesis was contained in the former. As an official he held office in 1799 as Minister of the Interior but only for six weeks, but afterwards he became a member, vice-president, and chancellor of the Senate. Under the Empire he was made a count and after the restoration a marquis. His later years were spent amid pleasant surroundings at Arcueil, where many paid homage to him. The last tributes to his memory were paid by Poissoin and Biot over his grave in Père la Chaise Cemetery, Paris, where he lay for sixty-one years. His remains were then exhumed and removed to Saint Julien de Mailloc, near his native place.

The modern treatment of leprosy is based mainly upon improved technique in the administration of chaulmoogra and hydnocarpus oils, or rather of the sodium salts or ethyl esters of their characteristic acids. In place of administration by the mouth, the drugs are now administered by intramuscular and intravenous injection, or by subcutaneous infiltration. Moreover, treatment is now continued over long periods of time. The bacillus of leprosy is a delicate organism, which can only secure a footing in an enfeebled host deprived of his natural powers of resistance by bad environment, scanty nutrition, or coincident disease. Residence under medical supervision in a well-organised leper colony suffices only to cure a small number of cases; the modern oil treatment has greatly increased the number of cures.

There are, however, still a considerable number of resistant cases, notably those of patients suffering from malaria, hookworm, or syphilis, who have been made vulnerable to leprosy infection. The difficulty is that the leper is apt to react to well-known drugs quite differently from the non-leprotic patient. Thus, Dr. E. Muir, of the School of Tropical Medicine and Hygiene, Calcutta, states that it is often dangerous to administer the usual arsenical drugs, such as neosalvarsan, to a syphilitic leper; so that it has become necessary to find a drug which combines the oil treatment referred to above with the antisyphilitic treatment for such cases. Such a drug has been prepared in the Wellcome Chemical Research Laboratories in London, under the direction of Dr. T. A. Henry, and has been tested since 1924 by Dr. Muir in India. The drug is a mercury derivative of metahydroxybenzaldehyde, rendered soluble in hydnocarpus or chaulmoogra oil, or in the ethyl esters made from these oils. It can therefore be injected in solution in these products, and the patient undergoes treatment for the two diseases at the same time. In the October issue of the *Indian Journal of Medical Research*, Dr. Muir gives the results of the treatment of thirty cases, all of which showed positive Wassermann reactions at the start. After treatment, sixteen became negative, two were doubtful, and only eight remained strongly positive, whilst all showed improvement so far as the concurrent leprosy was concerned. Not the least satisfactory feature of the new drug is its safety; in none of these cases did it give rise to undesirable symptoms.

ON Friday, Feb. 25, Sir Ernest Rutherford delivered the twelfth Guthrie Lecture to the Physical Society of London, assembled at the Imperial College of Science. Sir Ernest devoted the first part of his lecture to a description of the earlier work on the scattering of α-particles, which established the existence and charge of the nucleus; these experiments demonstrated that there is a wide region in the neighbourhood of the nucleus within which the inverse square law of force is obeyed, a remarkable point on which the lecturer laid stress. He then turned to the recent work on scattering carried out in the Cavendish Laboratory, in which, by the use of swift α-particles bombarding light nuclei, the law of force in the boundary regions of the nucleus itself has been investigated. Discussing the alternations of force which these experiments have established, he referred, not very hopefully, to the services which the new quantum mechanics might possibly render in elucidating the many puzzling features attending close collisions of nuclei. He concluded a fascinating lecture by describing a model of a radioactive nucleus, in which there is a nucleus within the nucleus, the inner nucleus possessing the full net positive charge, and being surrounded by circulating neutrons, *i.e.* α-particles neutralised by two electrons each. When such a neutron loses two electrons it is repelled and ejected as an α-particle. Sir Ernest appears to think that magnetic forces as well as electric forces will have to be invoked in future treatment of nuclear collisions.

IN his seventh Gifford Lecture in the University of Edinburgh, delivered on Friday, Feb. 25, on inorganic evolution, Prof. A. S. Eddington referred to the evolution of matter and of worlds as the beginning of a process which seems to reach its culminating point in the evolution of man. He reviewed the astronomical evidence bearing on the position of man in the universe—or in old-fashioned phrase, the 'plurality of worlds.' Is there reason to think that there exist other globes inhabited by beings which (however different physiologically) could be regarded as our compeers? In the solar system the two planets Mars and Venus are evidently the most eligible. Venus is swathed in thick clouds, and ideas as to what may lie beneath are entirely speculative. Mars presents a clear surface and invites more detailed study. On the important question of an atmosphere, it is now established that Mars has an atmosphere which, though thinner than our own, is probably adequate. Water is undoubtedly present, though in small amount. There are no oceans; but extensive clouds are occasionally photographed, and the white polar caps, which melt away entirely in summer, are snow deposits. Direct measurements of the surface temperature of Mars, by means of the heat-radiation from it, show that the climate is cold, but the temperature is not so low as to make life improbable. The remarkable feature is the regular seasonal change of the surface-markings. In the spring the dark markings spread greatly and encroach on the red (desert?) regions. It is not impossible that there may be some inorganic explanation, but the most natural hypothesis is that the change is due to the springing up of vegetation. If there is vegetable life, can we exclude animal life? But here the astronomer has come to the end of his facts and can take no responsibility for any further speculation. Prof. Eddington added that he does not think any weight can be attached to inferences sometimes drawn from the supposed artificiality of the so-called 'canals'; and further, it is exceedingly improbable that the zenith of evolution would happen simultaneously in two such widely different planets as Mars and the earth.

ON Mar. 1, the day preceding the delivery of the Frazer Lecture by Dr. Marett at Cambridge, Sir James and Lady Frazer entertained a number of friends at dinner in Trinity College. The presence in Cambridge of a large number of anthropologists for the purpose of attending the lecture, conferred upon the dinner a representative and official character, of which full advantage was taken to express the honour and esteem in which the author of "The Golden Bough" is held by his fellow-workers and disciples as well as by those eminent in other branches of learning. The eloquent and graceful tribute of Dr. Nairne, who proposed the health of Sir James Frazer, was followed by speeches from Lord Crawford and Balcarres, Chancellor of the University of Manchester, and Prof. E. Gardiner, formerly Vice-Chancellor of the University of London, on behalf of the universities, and by Mr. H. J. E. Peake, president of the Royal Anthropological Institute. The Rev. Edwin Smith spoke on behalf of workers in Africa, and Sir Frederick Whyte, first president of the Indian Legislative Council, represented India. The Master of Downing proposed the health of Dr. R. R. Marett as Frazer lecturer, and the latter in his reply referred to the sympathy and support given by Lady Frazer to Sir James in his work. Sir William Boyd Dawkins and Mr. E. N. Fallaize, honorary secretary of the Royal Anthropological Institute, who acted as chairman, also spoke.

A NEW quarterly periodical dealing with archæological matters is to appear shortly under the title of *Antiquity*. It will be edited by Mr. O. G. S. Crawford, Archæological Officer of the Ordnance Survey, Southampton, whose official position will serve as a guarantee that it will be closely in touch with recent discovery in England. The articles will be written by specialists, but will be popular in character and appeal to all who are interested in the development of human origins, dealing with archæological topics and giving news of current events more fully than is possible in the daily press, but in a more general form than in the technical journals. The periodical will have a wide scope and interest. Discoveries in Egypt, Mesopotamia, Crete, the Mediterranean, India, and Palestine will be given prominence; but British archæology will receive chief attention. A special feature will be the extensive use of air photographs for the purpose of illustration. In the list of contributions already promised a wide field is covered by writers of authority, including the more prominent continental archæologists. The subscription price is £1 per annum.

We have received copies of the November and December issues of *Rivista di Fisica, Matematica and Scienze Naturali* (Naples), these being the first numbers of the second series of this review, which was founded at Pavia in 1900 by Prof. Pietro Maffi, but came to an end in the early days of the War. A photograph reproduced in the December number of the journal shows that at the summit of Vesuvius there still exist portions of the vast abyss which was formed during the eruption of 1906 and was then about 300 metres deep but is now only 100 metres. Since the decapitation of the great cone was oblique with an inclination towards the north-east, in that quadrant the depth is barely 20 metres, so that a further flow of lava from this side may be expected. At the south-west quadrant of the crater platform there stands the small eruptive cone, which is about 60 metres high, but varies in height from day to day owing to the constant demolition and reconstruction caused by the almost continuous explosions of scoria. The filling of the abyss has been, and is still being, effected by the ashy materials emitted from the eruptive cone and by the lava extruded from time to time from radial crevices opening in the flanks of the same cone.

Sir Sydney Chapman, permanent secretary of the Board of Trade; Sir Alexander Gibb, consulting engineer; and Sir Israel Gollancz, secretary of the British Academy, have been elected members of the Athenæum Club under Rule II., which provides for election by the Committee of "persons of distinguished eminence in science, literature, or the arts, or for public services."

A flying expedition to the Antarctic is being planned by Senor Antonio Pauly, who recently laid his plans before the Sociedad Argentina de Estudios Geographicos. The *Geographical Journal* for February gives some details. The main idea involves the route originally proposed by Dr. W. S. Bruce and later adopted by Sir E. H. Shackleton, of a traverse of the continent from the Weddell Sea to the Ross Sea. But the starting-point will be Wandel Island on the west coast of Graham Land, which has been chosen on account of its level surface and accessibility by sea. Here a scientific station will be established, subordinate to the main expedition. A reconnaissance by air will establish an advanced base on the coast or in the interior of Graham Land about latitude 70° S., where a petrol depot will be formed. The final flight will be made from this base, landings being made *en route* for the purpose of scientific observations. By arrangement with the whalers in the Ross Sea, it is hoped to lay down depots of provisions in McMurdo Sound. The project holds out the prospect of useful scientific results, but the flight would be a long one through unknown atmospheric conditions, and its chance of success is not enhanced by the proposal to make several landings on the way. It is not proposed to start for at least another year.

The Ecclesiastical Commissioners have agreed to lease to the East Riding Antiquarian Society the old tithe barn at Easington, erected about A.D. 1500, and one of the few of its type still in existence, for the purpose of an 'out door' museum. In it will be exhibited the collections of obsolete farming appliances of various types and the large series of objects illustrating country life now in the possession of the Hull municipal authorities. Other exhibits will accrue, no doubt, as time goes on. The provision of alternative accommodation for the present tenant and other requirements will necessitate an expenditure of £645, towards which subscriptions are asked. This appeal is one which should be supported by all who realise the importance of preserving the fast disappearing relics of the local and peasant industries of England. Donations should be sent to Mr. T. Sheppard, The Museum, Hull.

The Electricity Bill having given its sanction to a great network for interlinking generating and distributing stations for electrical power in Great Britain, engineers are beginning to look ahead and study the problems which will have to be solved if continuity of supply is to be safeguarded. In a paper to the Institution of Electrical Engineers on Feb. 17, Mr. F. H. Clough read a paper on "The Stability of Large Power Systems," which is a question of ever-growing importance. He concludes that synchronous motors, that is, motors which run exactly in step with the generators, can be made sufficiently stable for all usual power supply purposes. It is necessary, however, to consider not only the maximum power for which the circuit has been designed, but also that which the system may have to carry momentarily if a fault develops. In America it has been found that even with 220 kilovolts between the transmission lines, quite satisfactory results have been obtained up to distances of 250 miles. When the length was increased to 400 miles the conditions for stability became apparently quite different. The problem in this case presents considerable mathematical difficulty.

FOR purposes of trans-Atlantic Telephony, the 'fifth' American zone, which comprises all places in the States of Washington, Oregon, California, Nevada, and Arizona, has now been made available. The charge for a call from any place in the fifth American zone to any place in Great Britain is £17 : 8*s.* for the first three minutes and £5 : 16*s.* for each additional minute or fraction thereof. A 'report charge' of £2 is made when a 'particular person' call cannot be effected. The whole of the United States is now in telephonic communication with the whole of Great Britain. The pioneers of this system deserve great credit for overcoming the many almost insuperable obstacles with which they were confronted, and for their patient perseverance. Research is being pushed forward with renewed vigour and we are looking forward to new developments.

MR. C. D. SHERBORN has presented to the Trustees of the British Museum (Natural History) the late Sir Richard Owen's first draft plan embodying his proposals, drawn up in 1859, for the Natural History Museum. The Department of Zoology has received from Mr. R. St. G. Burke 100 heads and skulls of Indian carnivora and ungulates, including an exceptionally fine series of Chital or spotted deer and five Sambar from the United Provinces. Dr. L. W. Sambon has presented to the same Department his collection of Linguatulida, a little-known group of parasitic animals generally regarded as being allied to the mites. Dr. Sambon's collection, which comprises 134 specimens, almost doubles the existing Museum collection of the group. The Department of Entomology has acquired some 22,000 specimens of insects, mainly Diptera, as a result of an expedition made by Mr. F. W. Edwards, a member of the staff of the Department, to north-west Patagonia. Recent donations to the Geological Department include thigh-bones of two plesiosaurs, one from the Kimeridge Clay of Dorset, the other from the Weald Clay of Sussex, from Dr. Pope Bartlett and Mr. S. Tooth respectively; and cephalopods and other molluscs from cretaceous rocks of Portuguese East Africa, presented by Dr. S. H. Haughton and Captain M. P. Traill-Smith, and from similar rocks in Great Britain by Lieut.-Colonel R. H. Cunnington. Dr. Hamshaw Thomas has given type-specimens of fossil plants (Bennettitales) from the Inferior Oolite of the Yorkshire coast. It is very satisfactory to note the increasing readiness of investigators to present to the Museum the specimens that have served as the basis of scientific work. During 1926 no less than 165 type specimens and 297 figured specimens were given by twenty workers at universities and similar institutions to the Geological Department. Indispensable as such specimens are to every serious student, their preservation is a fitting object of national concern.

IN the January number of the *National Geographic Magazine* (vol. 51, No. 1, Jan. 1927, Nat. Geog. Soc., Washington, D.C.), an account is given of the experimental work of Dr. W. H. Longley and Mr. Charles Martin on natural-colour photography under the sea, and eight illustrations—the first published—show the perfection to which they have attained. The work was carried out off the Dry Tortugas Island, the most western of the Florida Keys. A special technique was developed to hypersensitise the plates and so reduce the under-sea exposure to a twentieth of a second. This proved satisfactory in shallow water, but when it came to a depth of 15 feet a method had to be devised to supplement and intensify the light. A flash-light mechanism was therefore constructed which would float on the surface but yet be under the direct control of the submerged photographer to be guided by him and discharged as required. Two men in a dory followed the diver to maintain the necessary supply of air, but at a sufficient distance from the float to avoid any danger arising from the powerful explosions. The float was made of three pontoons supporting a dry-cell battery, the flash-light, each charge of which consisted of a pound of magnesium powder, and the white reflector. The camera used was enclosed in a brass case with a plain glass window in front of the lens. A supplementary hood was fitted above the regulation reflector, and by means of an acute-angled mirror the photographer was able to focus his instrument looking directly in front of him, a necessary measure owing to the difficulty of bending over the camera while wearing diving-dress. The photographs give a vivid impression of the wealth and variety of form and colour under the sea, those showing the colour-changes of the different fishes reacting to their surroundings being particularly fine.

AT the annual general meeting of the Optical Society, held at the Imperial College of Science, South Kensington, on Feb. 10, the following officers and members of council were appointed for the session 1927–28: *President*, Dr. R. S. Clay; *Vice-Presidents*, Mr. F. F. S. Bryson, Mr. H. H. Emsley, Mr. J. Guild, Mr. F. C. Watts; *Hon. Treasurer*, Major E. O. Henrici; *Hon. Secretaries*, Prof. A. F. C. Pollard, Imperial College of Science, South Kensington, S.W.7; Mr. W. B. Coutts, Artillery College, Woolwich, S.E.18; *Hon. Librarian*, Mr. J. H. Sutcliffe; *Editor*, Dr. J. S. Anderson; *Council*, Mr. D. Baxendall, Mr. W. M. Brett, Mr. E. F. Fincham, Mr. E. T. Hanson, Instructor-Commander N. M. S. Langlands, R.N., Prof. A. O. Rankine, Mr. H. C. Raxworthy, Mr. J. Rheinberg, Dr. G. F. C. Searle Mr. W. Swaine, Mr. R. S. Whipple, Colonel H. S. L. Winterbotham.

THE ninety-fifth annual meeting of the British Medical Association will be held in Edinburgh on July 15-23. According to the provisional programme, the incoming president, Sir Robert Philip, will deliver his address on Tuesday, July 19, at 8 P.M. Throughout the meeting the annual exhibition of surgical appliances, foods, drugs, and books will be open for inspection. The honorary local general secretary of the annual meeting is Dr. A. Fergus Hewat, 14 Chester Street, Edinburgh. A Lister Centenary Celebration is also being arranged at Edinburgh in July in connexion with the meeting. Throughout the week, a museum of Lister relics will be on view in the Upper Library of the Old University.

On July 20 a public meeting will be held, presided over by Lord Balfour, and Sir Watson Cheyne, Prof. T. Tuffler (Paris), Prof. Harvey Cushing (Harvard University), and Prof. James Stewart (Dalhousie University, Halifax, Nova Scotia) will deliver addresses. Inscriptions are to be placed on the walls of 11 Rutland Street and 9 Charlotte Square, both of which were occupied by Lister while in Edinburgh, and a prize of £25 and a gold medal is offered for an essay on "The Influence of Lister on Surgery," the competition being limited to first-year students of medical schools of the British Empire. A Lister memorial volume, edited by Dr. Logan Turner, is in preparation; in addition to personal reminiscences of Lister, it will contain chapters on surgery before and after Lister by Mr. Alexander Miles and Prof. Fraser respectively, while Sir E. Sharpey-Schafer will deal with Lister's work as a physiologist.

A useful catalogue (No. 148) of books on gardening and botany has just been circulated by Messrs. Dulau and Co., Ltd., 34 Margaret Street, W.1. It gives the titles of nearly 900 works classified under appropriate headings and should be of service to many readers of Nature. It will be sent free of charge to any applicant.

Applications are invited for the following appointments, on or before the dates mentioned:—An assistant chemist at the Fruit and Vegetable Preservation Research Station of the University of Bristol, Campden, Gloucestershire—The Resident Director, University of Bristol Research Station, Campden, Gloucestershire (Mar. 14). A keeper of the Birmingham City Museum and Art Gallery—The Town Clerk, Birmingham (Mar. 19). A director of research under the British Cotton Industry Research Association—The Secretary, British Cotton Industry Research Association, Shirley Institute, Didsbury, Manchester (Mar. 21). A headmaster of the R.N. College, Dartmouth—The Secretary, C.E. Branch, Admiralty, S.W.1 (Mar. 21). Chemical assistants in the public health department of the L.C.C.—The Clerk of the L.C.C., County Hall, Westminster Bridge, S.E.1 (Mar. 25). A director of research into the prevention of water pollution and cognate problems—The Secretary, The Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1 (Mar. 31). A lecturer in advanced and economic entomology in the University of Cambridge—The Registrary, University, Cambridge (May 31). A chemist and metallurgist in the Egyptian Government Assay Office, Cairo—The Chief Inspecting Engineer, Egyptian Government, 41 Tothill Street, S.W.1. An entomologist under the Sierra Leone Government, principally for tsetse fly investigation work—The Private Secretary (Appointments), Colonial Office, 38 Old Queen Street, S.W.1. A junior assistant in the physics department of the Experimental Station, Porton, Wilts—The Commandant, Experimental Station, Porton, Wilts.

Our Astronomical Column.

Brilliant Fireball on Feb. 25.—Mr. W. F. Denning writes: "This object appeared at 11.54 p.m. and caused a vivid illumination of the sky over the south-west of England. There was a double outburst resulting in two flashes of dazzling intensity. Some observers thought the size of the nucleus about equal to that of the full moon, but considered the luminous effect greater than that of the moon coming suddenly from behind dark clouds. The light was white, similar to that of magnesium. The flight was slow, and perhaps occupied 3 seconds in traversing 20°. A considerable number of descriptions are coming in from various places, but for scientific purposes very few are of use. Before the path of the body can be ascertained, more data must be awaited. There is a strong probability, however, that the meteor was directed from a radiant point in Leo and that it passed over the south-east region of Devonshire, falling from 66 miles to 26 miles in height at a velocity of 18 miles per second. Several large fireballs have been directed from this radiant (near Regulus) at the end of February in past years."

Solar Radiation.—In *Memoirs of the Imperial Marine Observatory*, Kóbe, vol. 3, No. 1, R. Sekiguti gives the results of an investigation undertaken by him for the purpose of detecting a possible direct effect of the sun's activity on air temperatures. The Greenwich daily sunspot areas are correlated with daily temperature rises observed for a standard type of weather. The meteorological data were collected from five stations in the plateau district of central Japan, and a selection was made from the years 1905–13 according to certain criteria of cloudiness, wind velocity, etc. The general conclusion advanced by the author is that there is an indication that small temperature rises occur with an inactive solar surface, and that moderate sunspot activity is responded to by high temperature rises. This conclusion is stated with diffidence, and the scantiness of the meteorological data and the difficulties of dealing with air temperatures for this purpose are frankly admitted.

The Sun's Motion derived from Faint Stars.—Perplexity has frequently been caused by the wide discordances between the positions of the solar apex when derived from stars of different magnitudes. These have in some cases been traced to systematic errors in the adopted proper motions. Mr. P. van de Kamp (*Bull. Astron. Instit. Netherlands*, vol. 3, No. 112) gives a new determination, based (1) on the photographically determined proper motions of 1900 tenth magnitude stars, uniformly distributed, but all north of declination −30°; (2) from the radial velocities of 105 stars of magnitudes 9-10 within 50° of the solar apex or antapex. The combined result for visual magnitude $10^{m}{\cdot}1$ gives for the apex, R.A. 277°±3°; Decl. 38°±3°, if Raymond's corrections are applied to Boss's proper motions in decl., or 31°±3° if van Rhyn's further corrections are applied; solar velocity 18±2·2 km./sec. for visual magnitude 9·2. These results are in fair accord with W. W. Campbell's values derived from the radial velocities of 2034 stars brighter than 5·5, namely, R.A. 268°·9±2·2, Decl. +27°·2±1°·7, Vel. 19·0±0·6 km./sec.

Research Items.

Prehistoric Cultures of Siberia. — While certain parts of Central Asia and Mongolia have recently attracted the attention of anthropologists and archæologists, the neighbouring country of Siberia remains scarcely explored in this respect. This consideration induced the State Russian Museum (formerly the Museum of Alexander III.) in Leningrad to send a palæ-ethnological expedition to the Altai mountains during 1924-1925. The expedition, under the leadership of Prof. S. J. Rudenko, explored in a systematic way a very large part of the country, and the results of the numerous excavations made indicate that the cultural life of the country was very intensive. The earliest remnants found belong to the later phase of the stone age; the skeletons found were brightly painted with ochre. About twenty places, with remnants of the bronze age, have been explored, and numerous articles, ornaments, and implements found. Some rather more recent stone graves discovered on the River Tchulishman contained, amongst other things, ornaments plainly indicating some connexion between the Altai nomads of those days and the Byzantinian culture.

The Indians of Huaxtec.—The recently published vol. 18 of the *Journal de la Société des Américanistes de Paris*, contains a study by Dr. Waltier Staub of the area known to the Aztecs as *Cuextlan* (Shores of the Salt Water), and to-day known as Huaxtec—land on the eastern side of the Mexican plateau, bordering on the steppe country of the north in which the culture of the nomad tribes contrasts with that of the settled agriculturists of the low-lying lands below. The special interest of this area from the ethnological point of view is that the inhabitants would appear to be an early offshoot of the Maya. At the time of their first settlement they would appear, judging from certain clay figures found in the alluvium of the Rio Panuco, to have been already acquainted with weaving and pottery-making. On the other hand, the absence of stone temples, of hieroglyphs, or any system of writing, indicates a fission before the Maya were acquainted with the calendar or had developed their system of writing. According to Lehmann and Sapper, the dialect which most closely resembles the Huaxtec of to-day is the Chicomucelotec of the frontier of Chiapas-Guatemala, their separation being due to an incursion of Totonacs and Olmecs towards the Atlantic coast. The geographical position of the Huaxtec country, borderings on the steppe lands, made it more suitable for hunting and fishing than agriculture, and it was thus left free from the intrusion of other peoples; while it was never occupied by the Aztecs, although it paid tribute to them. The inhabitants were thus able to preserve their culture and their language unaffected. The Huaxtecs of to-day are still extremely primitive, living in hamlets in bamboo circular huts, often without chairs or tables. They sleep on the ground and do not use the hammock. The principal deity of the pre-Columbian Huaxtecs was the earth goddess, and until recent years sculptured representations of her were frequently to be found on the hills, but of these many have now been removed for sale.

Nematode Eggs from Skin and Gills of Shark.—G. A. MacCallum records (*Proc. U.S. Nat. Mus.*, Vol. 67, Art. 16, 1925) the occurrence of the eggs of a nematode, probably a species of Capillaria, on the under surface of the nose, in front of the mouth, of a large shark, *Carcharinus commersoni*, taken near Woods Hole. The dark brown, almost black, eggs were laid in the groves between the scales and attached by transparent adhesive material. Similar eggs were found on the lighter coloured portions of the fins of another shark of the same species. In a later paper (vol. 70, Art. 6, 1926) the same author records eggs, tentatively referred to the genus Capillaria, on the gill arches of *Carcharinus milberti* at Woods Hole. These eggs are in patches, sometimes two inches long by half an inch wide, and the egg shell is spinous. In neither case were adult worms found which could have laid the eggs.

Creeping Eruption in America.—A short note in the *Official Record of the U.S. Dept. of Agriculture*, vol. 5, No. 43, Oct. 1926, summarises the recent work on creeping eruption in man by J. L. Kirby-Smith, W. E. Dove, and G. F. White (see *Arch. Dermatology*, 13, 1926, pp. 137-173). The eruption is caused by a nematode larva. During a further study, Messrs. Dove and White have recovered infective nematode larvæ from the fæces of the dog and the cat in a locality where there was a high incidence of creeping eruption. The larvæ were applied to the human skin and produced the characteristic symptoms and lesions. These larvæ have "in general the appearance of hookworm larvæ." In 26 out of 27 dogs from the streets of Jacksonville and in both of two cats, Ancylostoma were found and two species identified as *A. braziliense* and *A. caninum*. The authors state that further work is in progress. Creeping eruption occurs chiefly in the South Atlantic and Gulf States, but it has been reported so far north as New Jersey and inland so far north as Oklahoma. Damp sand in these areas has been observed to be a favourable environment for the parasite and a likely location for infection.

Medusæ of the Danish Ingolf-Expedition.—Dr. P. L. Kramp, of the Copenhagen Zoological Museum, gives a most interesting account of the Anthomedusæ of the Danish Ingolf-Expedition (vol. v. 10, Medusæ, Part 2, Copenhagen, 1926). This work follows the same plan that was used in the Leptomedusæ (Kramp, 1919) of the same expedition, the main study being the horizontal and vertical distribution, seasonal occurrence and dependence on the various hydrographical conditions. Whilst keeping these points in view, however, the author is able to show a great deal that is new with regard to the comparative morphology of many of the species, especially of those belonging to the Codonidæ. Such points as the structure of the manubrium, morphology of the tentacles and their basal bulbs, and the abaxial spurs are dealt with in detail and show important features useful in classification. *Sarsia tubulosa*, that common and much-discussed species, or group of species, is fully investigated, the conclusion being that most of the closely related forms such as *S. decipiens*, *S. pulchella*, and *S. mirabilis* are merely local varieties. An interesting point is shown in the fact that the farther north it is found the more the time of occurrence of this medusa is delayed, the liberation from the hydroid taking place later in the colder regions. That the farther north we go the later the medusa is budded off seems to be a general principle for these northern forms. The author places *S. flammia* in the genus Euphysa, having found therein certain muscular bands which probably do not exist in Sarsia. *Corymorpha nana* is the hydroid of *Euphysa aurata*, the latter probably being a separate species from *E. mediterranea*. Interesting facts are noted amongst those proliferating medusæ *Lizzia blondina*, *Rathkea* *octopunctata*, and *Hybocodon prolifer*. In the first species, apparently all the young specimens normally bud and later on each one becomes sexually mature, whereas in the other two the first budding generations probably never become sexually mature. The budding of Rathkea in one and the same area is dependent on the water temperature, being accelerated and ceasing earlier when the water is warm than when it is cold.

The Biology of the Saw-toothed Grain Beetle.—In the *Journal of Agricultural Research*, vol. 33, No. 5, 1926, Messrs. E. A. Back and R. T. Cotton record a number of interesting observations on the biology of this cosmopolitan insect. Although it may occur in almost any stored food of vegetable origin, and has been known for more than 150 years, the life-cycle of *Oryzæcephalus surinamensis* Linn. has received but little attention from entomologists; even Redi in 1671 figured an insect which is very possibly this same species. Linné received specimens from Surinam, and for that reason gave it the specific name by which it is known. A remarkable fact brought to light by Messrs. Back and Cotton is the longevity exhibited by the adult beetle. Under laboratory conditions, male individuals lived more than two years, and one example survived for three years and three months. The females appear to be shorter lived; few lived longer than one year, but one example survived for two years and eight months, laying 216 eggs during that period. Under the most favourable weather conditions, the whole life-cycle may be passed through in 27 days. On the other hand, low temperature may prolong the period to 315 days. At Washington, D.C., there are four or five generations annually, but in the tropics there are doubtlessly more. It is interesting to note that a temperature of 0° to 5° F. for one day will kill all stages, and if the temperature be raised to 125° F. all stages succumb within an hour. A vacuum of 29 in., continued for seven hours, killed the adult insects.

The Landfall of Columbus.—In a paper read before the Royal Geographical Society on Feb. 14, Lieut.-Commander R. T. Gould returns to the much-debated question of which island in the Bahama group Columbus first sighted. Since the original journal of Columbus is lost, the available evidence is circumstantial and indirect, and at best can indicate only the most probable island. At the outset Commander Gould dismisses, as unsupported by any evidence, the suggestion that volcanic disturbances or changes in sea-level may have altered the appearance and distribution of the islands since Columbus's voyages. The island which Columbus named San Salvador was clearly one of the Bahamas and has been variously identified with Cat, Grand Turk, Watling, Mariguana, and Samana Islands. Commander Gould discusses in turn the grounds for each identification in the light of the evidence available. This falls under several heads; (1) Courses and distances sailed by Columbus between his departure from Gomera in the Canaries and Guanahani, the native name of his landfall, for which the material is very scanty; (2) evidence from the small-scale chart of Cosa (1500) or the chart of Herrara (1601); (3) comparison of Columbus's description of Guanahani with the various likely islands as they exist to-day; (4) plotting on a modern chart the relative bearings and distances of the islands discovered by Columbus. The result of each line of researches leads Commander Gould to the same conclusion, that Columbus's landfall was Watling Island, now also known as San Salvador.

Mineral Deposits in Russia.—Results of current research in mineralogy in Russia are being published mainly by the Institute of Applied Mineralogy and Metallurgy in Moscow, and by the Geological Committee of Leningrad. The Moscow Institute published during 1926 some ten papers of considerable practical and theoretical interest, including the results of original investigations on the chemistry of minerals by Ginsberg, and on kaolin and other deposits in the Urals. An outstanding work is that by V. A. Obrutchev on "Metallogenetic Periods and Regions of Siberia"; the author finds six separate metallogenetic periods in Siberia; Archean (numerous deposits of gold, and several of iron, silver, lead, and molybdenum); Eozoan (still more gold, some copper, iron, and tungsten); Caledonian (little gold; deposits of copper, silver, lead, zinc, and tungsten also not numerous); Hercynian (gold deposits rare, but those of polymetallic ores numerous; some tin, tungsten, and mercury); Tian-Shanian (polymetallic ores prevalent; nickel, platinum, copper ores); Meso-Neozoan (gold, copper, silver, lead, zinc, iron, bismuth). A geo-morphological survey of Siberia is given by the author and important bibliography appended. In the series of publications by the Leningrad Geological Committee there is an interesting report by A. D. Natsky on the sulphur deposits in the Karakum desert of Turkestan; M. M. Tetaiev gives a classification of Russian tungsten ores, and A. K. Meissner presents an almost monographic description of gold deposits of Russia.

Devonian Flora.—The most important contribution to Devonian palæobotany since the discovery of the Rhynie fossils is described by Dr. Dukinfield Henry Scott in the *New Phytologist* (vol. 25, No. 5). The new specimens, which came from several localities near Elberfeld and belong to the lowest division of the upper Middle Devonian, have been investigated by Drs. Kräusel and Weyland (*Abhandlungen der Senckenbergischen Naturforschenden Gesellschaft*, Bd. 40, Heft 2, 1926). So far they have described the following five plants: *Asteroxylon elberfeldense* n.sp., *Aneurophyton germanicum* K. and W., *Hyenia elegans* n.sp., *Calamophyton primaevum* n.gen. et sp., *Cladoxylon scoparium* n.sp. There is a far-reaching agreement between the Elberfeld and the Rhynie Asteroxylon. They differ, however, in the presence of pith in the German form, in the stellate form of stele, and in the occurrence of pitted tracheids. Aneurophyton was probably a tree with the habit of a tree-fern, and its frond structure may throw some light on the question of the origin of the fern-like frond. The chief point of interest in regard to *Hyenia elegans* is the presence of the fructification, previously unknown in the genus, and taking the form of loose spikes with numerous forked sporangiophores arranged on the axis. On account of the dichotomous branching, *H. elegans* and *Calamophyton primaevum* are relegated to two distinct series of a new class, the Proto-articulatæ, although, in view of the close agreement in the structures of their fructifications, there seems some reason for including them in one series. The last species, *Cladoxylon scoparium*, is an unexpected find in the Middle Devonian, and the external habit and the fructification, hitherto unknown, have now for the first time been revealed. "The discovery of this Middle Devonian species must reopen the disputed question of the Upper Devonian or Lower Carboniferous age of the Saalfield Cladoxylons."

The Spectrum of Argon.—A few years ago, F. Paschen succeeded in analysing the complicated line spectrum of neon. A similar analysis has now been effected for the 'red' spectrum of the next inert gas, argon. In two recent papers (*Zeits. f. Phys.*, 39, p. 172, and 40, p. 839) K. W. Meissner has shown that this, too, can be derived from four sets of *s*-terms, ten of *p*-terms, and twelve of *d*-terms. Most of the wave-numbers are from his own measurements, but some lines observed by other workers in the ultra-violet fall into the same scheme. An interesting consequence has been pointed out by W. Grotrian (*idem*, 40, p. 10). The screening effect of the inner electrons for the X-ray $M_{II}M_{III}$ doublet in the heavy elements, in which the *M* shell of electrons is complete, is such as to reduce the effective nuclear charge by 8·5. Meissner's analysis shows that the screening constant is 7·3 for argon, where only the first eight electrons of the *M* shell are present; for the next element, chlorine, its value is 7·5.

Structure of the Molecule of Carbon Monoxide.—Recently spectroscopists have been able to show, from the analysis of some carbon band spectra, that the outer electrons in an excited carbon monoxide molecule have energies which fall into a scheme very similar to that for an atom of the second group of the periodic table. This analogy has now been extended by F. L. Mohler and P. D. Foote (*Phys. Rev.*, 29, p. 141, 1927). By the 'partial current' method for measuring excitation potentials, the effect of inelastic collisions of an electron with gas molecules is shown by the change in the electron current to a collecting electrode as the energy of the electrons is varied. When such experiments are made with carbon monoxide and mercury vapour under comparable conditions, the current–voltage curves obtained exhibit an astonishing similarity. The form of the curves yields information about the relative probability of occurrence of the possible quantum transitions, and it is concluded that not only the energy levels, but also the movement of a valence electron from one to another of them, are alike in the respective molecules and atoms.

The Pycnosonde.—A new instrument for measuring the specific gravity of sea water, invented by Dr. D. la Cour of the Danish Meteorological Institute, is described in the *Marine Observer* for March. It consists of a glass tube bent twice at right angles and fixed on a metal frame for protection. One branch of the tube is narrow and the other wide. The narrow end is open and the wide end is closed by a water-tight valve opening inwards. As the tube is lowered in the sea the increasing pressure slowly forces water in through both ends and the air is compressed in the upper part of the wide arm. When the instrument is hauled up the valve keeps closed as the pressure decreases, and the expanding air escapes by the narrow arm. When the surface is reached the wide arm contains a complete sample of the various waters through which the instrument has passed, arranged in the proper order. In the wide arm, before lowering, are arranged small coloured glass floats—pycnodevils—of certain specific gravities. They assume positions in the column of water corresponding to certain definite values. Thus when the pycnosonde is brought out of the water the pycnodevils have arranged themselves at different heights, and the depths to which these heights refer can be readily determined by a suitable scale. It has been found in practice that there is no appreciable mixing of the layers of water in the tube even when the temperature of the whole instrument is altered. It is claimed that in shallow water this instrument works well, and can be used from a moving vessel with the Kelvin sounding machine.

Micromagnetic Oscillations at Zouy.—In *Terrestrial Magnetism* for September 1926, Arnold Podder, of the Meteorological and Magnetic Observatory at Zouy (formerly Irkutsk), Russia, discusses the micromagnetic oscillations observed there by sensitive magnetographs. Two very different types of these waves are found to exist; in one the vibrations continue very regularly for hours or even days, with well-defined periods of from 5 to 15 seconds. In the other type the vibrations, though less regular, have a pronounced periodical character, the periods being considerably longer, however, with an average value of about 35 seconds. A year's observations are discussed, relating to all three magnetic elements; the vertical force observations were made both by a balanced magnet and by a horizontal coil. In the short-period oscillations the intensity increases with the period (from about 0·5 γ for 5 seconds period to about 2·5 γ for 15 seconds period—the intensity being nearly the same in the horizontal and vertical components); 90 per cent. of these vibrations have periods between 7 seconds and 9 seconds. They occur particularly between midday and 7 P.M. local time, while at night the longer periods are more prominent. No hypothesis is advanced as to the cause of the vibrations, but certain similarities to microseismic waves are pointed out.

Formation of Ammonia in the Silent Discharge.—Warburg and Rump (*Zeit. fur Phys.*, vol. 40, p. 557, 1926) have recently studied the formation of ammonia in the silent discharge and have compared the results with those obtained in the production of ozone by the same method. A mixture of nitrogen and hydrogen was passed so quickly through a Siemens' tube that the amount of ammonia formed was so small that any decomposition could be neglected. It was found that the ammonia was formed chiefly at the walls, whilst the ozone is formed chiefly in the interior of the discharge tube, probably because of the greater heat of dissociation of nitrogen and the catalytic action of the surface of the tube. Variation of pressure produced very much less effect in the case of the production of ammonia than in the case of ozone, presumably because the number of ionic collisions at the walls was very small compared to the number in the interior of the gas.

Characterisation of Genuine Proteins.—The Hugo Muller Lecture, which was delivered before the Chemical Society by Prof. S. P. L. Sorensen on Oct. 28, 1926, has been published in the Society's *Journal* for Dec. 1926, and it gives an account of some of the diverse problems which, at the present moment, occupy the attention of those engaged in a study of the composition of the proteins. These problems are of two kinds: the first deals with the nature of the simpler compounds from which the protein molecules are built up, while the second is concerned with their 'elementary' composition. The decomposition products which can be obtained by treating the proteins with acids, alkalies, or suitable enzymes, form the most important clue as to protein structures, and about twenty such substances are now known. It is considered that protein molecules consist of a number of loosely knit polypeptide complexes, and this view accounts for the remarkable properties that the proteins possess. With regard to their elementary composition, it is well known that all protein substances contain carbon, hydrogen, oxygen, and nitrogen, and most of them also small quantities of sulphur and phosphorus. Since the sulphur and phosphorus contents are small, it has been suggested that the sulphur- or phosphorus-containing compounds are only loosely associated with the protein molecules, and are not integral constituents of them. Careful fractionation has shown that this is true of the serum proteins, but the phosphorus in egg albumen appears to be intimately bound up with the rest of the molecular complex.

The Genetics of Wheat Species.

RECENT years have witnessed important advances in our knowledge of the wheats, which are now recognised to fall into three well-marked groups, differing in their chromosome numbers and rust resistance, and showing inter-sterility when members of different groups are crossed. Much genetical work has been devoted, not only to crosses between hexaploid and tetraploid or tetraploid and diploid species, but also to crosses between species having the same chromosome numbers. In the latter series of crosses, in which there is relatively full fertility, various investigators, including Tschermak, Nilsson-Ehle, Engeldow, Percival, Kajanus, and Malinowski, have taken part. The results of these crosses between wheat species having the same chromosome numbers have been much simpler than might have been anticipated, and they raise some interesting questions concerning the relationships between these species, the nature of the differences involved, and the manner in which these differences are germinally represented.

Some of these questions are discussed in a recent paper by Prof. E. Malinowski (*Jour. of Genetics*, vol. 17, No. 2), in which he propounds the view that the phenomena can be explained by assuming linkages between different pairs of chromosomes. Such linkages would resemble in some respects those which are known to occur between many of the chromosomes of Oenothera species. Such connexions between chromosomes have not yet been described as regular occurrences in the wheats, although much cytological work has been done on this group, and there are other difficulties with the hypothesis proposed, which, nevertheless, will doubtless lead to a further analysis of the differences between species of wheats.

In 1914, Malinowski found that a cross between the two hexaploid wheats, *Triticum Spelta* and *T. vulgare* (each with 42 chromosomes), gave an intermediate F_1 and an F_2 which contained *T. Spelta*, the intermediate type, and *T. vulgare* in the ratio 1 : 2 : 1, although an independent factor for *T. compactum* (club wheat) was also present. Kajanus confirmed the 1 : 2 : 1 result. Now *T. Spelta* has longer ears than *T. vulgare*, and its glumes and spikelets also have a different shape. Hence, in spite of the monohybrid behaviour, it appears probable that a number of (linked) genetic differences are involved. Whether it is necessary to assume that these factors reside in independent chromosomes which have become linked, as Malinowski suggests, remains to be seen.

In crosses between *T. polonicum* and *T. dicoccum*, both tetraploid species with 28 chromosomes, the same 1 : 2 : 1 ratio is obtained in F_2, although here again an independent factor for long or short glumes may be present. The same ratio obtains when *T. polonicum* is crossed with *T. durum*, another tetraploid species.

When a tetraploid is crossed with a hexaploid wheat, the results are much more complicated. For example, in *T. polonicum* × *T. vulgare* the F_1 pentaploid hybrid is intermediate, but the F_2 segregates into a great variety of types, including *T. dicoccum*, *T. durum*, and *T. polonicum* ($4n$ chromosomes), as well as *T. Spelta* and *T. Vulgare* ($6n$). Some of the F_3 families show segregation between two species in a 1 : 2 : 1 ratio. But they are always both tetraploid or both hexaploid species, *i.e.* they might be *durum* and *polonicum*, or *dicoccum* and *polonicum*, or *vulgare* and *Spelta*. The least complicated segregation between forms having different chromosome numbers is in crosses between *T. dicoccum* and *T. Spelta*. This yields in F_2 *dicoccum*, *Spelta*, and two other types which resemble these respectively.

In his explanatory hypothesis Malinowski assumes that the tetraploid wheats have two linked chromosomes, while the hexaploid forms have three, and that certain of these linked chromosomes are common to different species, *e.g.*, *T. dicoccum* having *a* and *c* linked, while *T. Spelta* has *a*, *c*, and *e* linked. As it seems probable that the hexaploid wheats have arisen at some time through a doubling of the chromosomes in a sterile hybrid between a diploid and a tetraploid species, the tetraploid and hexaploid wheats might be expected to have certain chromosomes in common. Whatever the explanation, these apparent linkage phenomena in wheat species are of much interest, and their elucidation may well mark another step in the advance of genetic theory.

Tschermak and Bleier (*Ber. Deut. Bot. Gesells.*, vol. 44, p. 110) have recently obtained a constant fertile octoploid hybrid by crossing *Aegilops ovata* with *Triticum dicoccoides* and *T. durum*. This they believe supports Percival's hypothesis that the hexaploid wheats arose from crosses of *T. dicoccoides* with Aegilops. But Percival (*Jour. Genetics*, vol. 17, p. 60) has found that Aegilops itself contains species with $2n$, $4n$, and $6n$ chromosomes.

Another set of results bearing closely on these problems is derived from the work of Prof. G. C. Meister with his wheat-rye hybrids (*Saratov Agr. Exp. Station*, I, p. 220, 1923). Six generations have been grown from the original natural crosses and a multitude of forms has been obtained, but the 'F_2' consisted of uncontrolled back-crosses with the parents. The parent wheat was hexaploid and the rye diploid, the hybrid F_1 being tetraploid. Chromosome studies combined with genetical examination of the later generations should make possible an analysis of what is happening—whether merely recombination of factors already present or whether germinal changes of various possible kinds are responsible for the appearance of some of the new types. How, from a single species of wheat when crossed with rye, a whole series of wheat species and varieties, some of which are already well known, should arise, is not at present clear; but the elucidation of this problem should add much to our understanding of the relationship between different species of wheat. One of the forms thus obtained is very similar to *T. persicum*, a tetraploid wheat. A full study of the chromosomes in these hybrids may be expected to throw light on the relation between crossing and mutation, and also on the relationships between wheat species.

R. RUGGLES GATES.

The Recolonisation of Krakatau by Animal Life.

THE gradual recolonising of the island of Krakatau with plants and animals subsequent to the catastrophe of 1883 is a subject of great biological interest. Dr. K. W. Dammerman, of the Buitenzorg Museum, tells us that after studying the new fauna of Krakatau it was desirable to compare it with that of some similar neighbouring island which had remained unaffected by volcanic convulsions. After taking various islands into consideration, the nearest suitable *terrains* for such comparison appeared to be Durian—a member of the Rhio-Lingga archipelago. It has about the same area as Krakatau and is situated between the bigger island of Sumatra and the Malay Peninsula (just as Krakatau lies between Java and Sumatra). The whole island is clothed with virgin forest, it has been little interfered with by man, and, for a very long time, no volcanic eruptions have devastated its fauna and flora. The fauna of Durian proved somewhat disappointing, owing to the poor soil and the resulting rather scanty vegetation. No Ficus of any kind, for example, was detected on the island, and, it may be added, trees of the fig tribe are one of the most attractive for birds, insects, and other animals.

Dr. Dammerman states that the research on the fauna of Durian[1] was wholly planned for the purpose of comparing it with that of Krakatau—to ascertain what Krakatau's fauna possibly was before the eruption, and what it is likely to consist of in future. Taking the whole fauna into consideration, he finds that the total number of species of animals on Krakatau at present is about 62 per cent. of that of Durian, but, with regard to individual groups, very different figures reveal themselves. As regards the vertebrates, Krakatau is far behind Durian with 47 per cent.. but considering terrestrial forms alone, and excluding birds and bats, Krakatau has only 21 per cent. of the forms inhabiting Durian. With the invertebrates the poorness of Durian Island is noticeable, as Krakatau already has 93 per cent. of the number of invertebrates of Durian. Of insects only, Durian has a great majority, having about 40 per cent. more than Krakatau.

The remarkable conclusion of Dr. Dammerman's comparison is that Krakatau has regained about 60 per cent. of its normal fauna after a lapse of about forty years, on the supposition that the fauna of Durian is a normal one for the comparison. He maintains that the fauna of Krakatau will be complete, not after centuries, but within a comparatively short time, much shorter than might reasonably have been anticipated. The fauna is likely to become much richer than that of Durian to-day, on account of its more fertile soil and luxuriant vegetation.

Excluding bats, of which certainly many more species will reach Krakatau in future years, nine terrestrial mammals occur on Durian against only one on Krakatau. This species, the common Malay house rat, seems to have come in about 1917, but when the island was revisited in 1924 it appeared to be on the verge of extinction. This conclusion is in accordance with the theory that house rats are unable to thrive away from human dwellings. The field rat, and possibly other species, are to be expected together with the Malay macaque and the commoner kinds of wild hogs. Of the birds, it is anticipated that the fauna will become about twice as rich as it is nowadays, but fresh water being absent on Krakatau, such birds as are dependent thereon will have no chance of survival should they arrive on the island. Among the reptiles, the lacertilian *Lygosoma atrocostatum* is now abundant, whereas in 1921 the species is stated certainly not to have been there, and the same applies to the crocodile. Among the insects, Hymenoptera are not anticipated to show rapid increase of species in the future, but Coleoptera and Lepidoptera are still far from their maxima.

In short, it appears that on new land, carnivorous animals are later invaders than vegetable feeders, and on Krakatau there are as yet no insectivorous bats or other carnivorous mammals, Cicindelidæ, or predaceous flies. Other groups of raptorial insects such as Mantidæ and Neuroptera are rare. The exception appears to be the spiders, which are unusually abundant. This is explained on the basis of the extraordinary ease by which Araneæ are spread, and the fact that they thrive largely on flying insects, which are those which would reach the island early in the process of repopulation.

It is noteworthy that three species of Oligochæta (against two species on Durian) have reached Krakatau, but, as might be expected, there are no freshwater Crustacea or Mollusca, but land members of the two latter groups are represented by three and six species respectively.

A. D. IMMS.

British Industries Fair.

THE British Industries Fair, which is organised annually by the Department of Overseas Trade, was held on Feb. 21-Mar. 4 at the White City, London. A section of the Fair was held at the same time at Birmingham, mainly for hardware and engineering exhibits. Evidence of the increasing popularity of the London fair was provided by the Department being able to issue a detailed catalogue six weeks before the opening, all the exhibiting space available having been reserved by that date.

The dominating exhibit of the chemical section was arranged by the Imperial Chemical Industries, Ltd., the combine recently formed by Brunner, Mond and Co., Ltd., Nobel Industries, Ltd., the United Alkali, Ltd., and the British Dyestuff Corporation, Ltd. The exhibit was designed to show the wide range of products obtained from raw materials in general use, such as sulphur, coal, brine, and limestone. Nitram, Ltd., a subsidiary company, demonstrated in an interesting way the new principle in use for fertilising grazing land.

Another exhibit of chemical interest was the new fresco medium (silicon ester fresco) which by offering the artist a new medium may revive an ancient art some of the secrets of which have been lost. Silicon ester is said to form as convenient a medium as oil, and to combine the fluidity and facility of water colour with the strength and depth of oil. It is hoped that this discovery will lead to a revival of large mural decorations. The firm interested in silicon ester fresco—Messrs. Albright and Wilson, of Oldbury—are also promoting the use of silicon ester for consolidating and protecting the surface of decaying stone and for imparting a new siliceous face to terra-cotta in the early stages of decay. The silica is deposited in an adhesive and non-crystalline form. Remarkable success has been obtained in the restoration of decayed stone-work in old buildings by the use of this material.

Improvements in the reproduction of sound by gramophone were shown by Messrs. C. Gilbert and Co.—a Sheffield firm—who demonstrated their tone reflector, an instrument for producing great volume of sound without distortion. Among the radio exhibits the Priory loud speaker made by a Newport Pagnell firm deserves a word of commendation.

Several firms exhibited aids for the deaf. The National Institute for the Deaf has strongly advised sufferers to consult an ear specialist to ascertain whether the deafness is of a type likely to be helped by an artificial aid and to deal only with a firm willing to allow a home trial of two or three weeks before purchase. This warning is without doubt necessary, and should be widely advertised to prevent the exploitation of sufferers. Good progress is being made in electrical aids, but older forms of aid are also receiving attention. Mr. Geo. W. King, proprietor of the British Acoustic Co., himself a sufferer, showed some light and comfortable pairs of horns, the use of which by deaf people will probably become more general in future.

Another exhibit of medical interest was the "Magic Blanket," produced by the Radiocoil Electromagnetic Blanket, Ltd., of Manchester Street, London, W.1. This blanket has more than 12,000 feet of specially prepared wire covered with downy material, the inner surface being thickly quilted. Its use is recommended by the makers for sufferers from various diseases. An induction pad is also provided to be used in conjunction with the blanket. This pad gives a rise of temperature in the blanket from 50° to 130° F. in sixty minutes, and profuse perspiration is obtained in forty-five minutes.

The Linguaphone Institute exhibited gramophone records for learning foreign languages. These records reproduce the speech of well-known elocutionists in various languages. The advantages of this simple method of learning foreign languages are obvious, and it is not surprising to learn that the records are used by more than 900 schools, colleges, and universities.

These few notes by no means exhaust the exhibits of scientific interest. The catalogue shows in the section of "Chemical and Allied Products" that a large number of British firms are engaged in the production of chemicals, drugs, dyes, fertilisers, insecticides, perfumes, and photographic materials. Makers of scientific and optical instruments are also well represented.

The Fair was visited by the King and Queen, and attracted a large number of buyers and other visitors.

University and Educational Intelligence.

Cambridge.—Mr. Ramsay, Master of Magdalene College, and Mr. Thirkill, Clare College, have been elected members of the Council of the Senate. Prof. W. J. Dakin, of the University of Liverpool, has been nominated to use the University table at Naples next April, and Mr. J. Gray, King's College, to use the University table at the laboratory of the Marine Biological Association at Plymouth next July.

Edinburgh.—At the meeting of the University Court on Monday, Feb. 21, Dr. R. J. Clark was appointed lecturer, and Carnegie teaching fellow, in the Department of Natural Philosophy.

It was announced that Mr. Thomas Cowan had offered a sum of £15,000, supplementary to previous gifts, in order to enable the University to carry out a projected scheme for providing a residential house for men-students. Mr. Cowan has already given £15,000 to the University, £10,000 of which was contributed in appreciation of the work done by students during the general strike of 1926.

London.—Five addresses, spread over the period February-June, have been arranged as part of the centenary celebrations of University College. The speakers include Prof. E. H. Starling, on "A Century of Physiology" on Feb. 28, and Sir Oliver Lodge, on Mar. 14, at 8.30 p.m., on "A Century's Progress in Physics."

Manchester.—The Council has accepted the resignation of Prof. W. W. C. Topley from the chair of bacteriology and the directorship of the public health laboratory as from September next, when he will take up his duties as professor of bacteriology and immunology in the new London School of Hygiene and Tropical Medicine.

Mr. W. O. Howarth, lecturer in botany, has been appointed to supervise research in mycology under the scheme of the British Empire Cotton Growing Corporation. Mr. H. G. Chippindale has been appointed research assistant in mycology under the same scheme.

Calendar of Discovery and Invention.

March 7, 1785.—Among the landmarks in the history of geology was the publication of James Hutton's "Theory of the Earth: or an Investigation of the Laws observable in the Composition, Dissolution, and Restoration of Land upon the Globe," read to the Royal Society of Edinburgh on Mar. 7 and April 4, 1785. It attracted little attention at the time, but ten years later Hutton published his views in two volumes, and in 1802 Playfair wrote his "Illustrations of the Huttonian Theory of the Earth."

March 8, 1618.—Searching for a simple relation which would connect the distances of the planets with their times of revolution, Kepler found after long calculation that the square of the time in which a planet revolves round the sun is proportional to the cube of the average distance of the planet. This, he said, first occurred to him on Mar. 8, 1618, and two months later he recognised the absolute truth of a principle for which he had been searching for seventeen years.

March 9, 1720.—Halley succeeded Flamsteed as Astronomer Royal.

March 9, 1862.—A fight which revolutionised sea warfare took place in Hampton Roads, U.S.A., on Mar. 9, 1862. The ***Monitor***, Ericsson's famous ship, there met the ***Merrimac***. The ***Monitor***, "a fort upon a raft," carried two 11-inch guns in a revolving turret. The ***Merrimac***, a converted 40-gun frigate, had six 9-inch, two 7-inch, and two 6-inch guns. The fight was in the nature of a duel and was inconclusive, but from that time dates the introduction of the turret, advocated by Ericsson in America and Cowper Coles in England.

March 10, 1809.—Founded in 1807, the Geological Society at first took the form of a dining club, and some members wished that it should be regarded as an assistant association of the Royal Society. This, however, did not meet with general approval, and on Mar. 10, 1809, a resolution was passed "that any proposition tending to render this Society dependent upon or subservient to any other society does not correspond with the conceptions the meeting entertains of the original principles upon which the Geological Society was founded."

March 12, 1683.—Geological maps were first suggested by Martin Lister, who on Mar. 12, 1683, read to the Royal Society "An ingenious proposal for a new sort of Maps of Countrys, etc."

March 12, 1782.—Watt's grand improvements in the steam engines were set down in four patents. His first patent contained the important inventions of the separate condenser and air-pump; his second describes devices for obtaining rotary motion. The date of the third patent is Mar. 12, 1782, and in this he makes a claim for a double acting engine and for using the steam expansively. To these several improvements he added the throttle valve, the parallel motion, the centrifugal governor, and the indicator.

March 12, 1884.—Two pioneers whose efforts gave a great impetus to the utilisation of electric energy were John Dixon Gibbs and Lucien Gaulard. In Paris in 1881 they produced a "secondary generator," an improved form of which was patented on Mar. 12, 1884. Their system of distribution was used in London in a portion of the Metropolitan Railway, and also for lighting Regent Street and Oxford Street. Though when judged by present-day standards their secondary generators appear crude pieces of apparatus, they were the forerunners of the present-day transformers. E. C. S.

Societies and Academies.

Paris.

Academy of Sciences, Jan. 24.—**E. Goursat**: A problem of the theory of surfaces.—**F. E. Fournier**: The inclination θ, always favourable to the speed of a ship, that its satellite wave gives to its plane of flotation, in a calm sea.—**F. W. Perkins**: The resolution of the problem of Dirichlet.—**André Roussel**: The ensembles of equally continuous functionals.—**G. Sugot**: The gyroscopic movement of a projectile.—**P. Dejean**: The influence of compression on the fragility of steel. The existence of a limit of fragility.—**Léon Bouthillon**: The inclination of [electromagnetic] waves and directed systems.—**E. Brylinski**: The relative velocity of the earth and the neighbouring ether. A. Picard and E. Stahel have described the results of experiments which they regard as opposed to the conclusions of Miller, based on experiments at Cleveland and at Mount Wilson. The author shows that the two series of experiments, regard being had to the possible errors, are really in agreement.—**Léon and Eugène Bloch**: The spark spectra of bromine. A list of lines in the E_1 and E_2 spectra between wavelengths λ6353 and λ2338.—**Paul Riou**: An apparatus for measuring the rates of absorption of gases by liquids. A description, with diagram, of an apparatus for determining the rate of absorption of a gas by a liquid.—**Mario A. da Silva**: A new determination of the period of polonium. The method is based on the determination of the ionisation produced in pure argon by the α-rays of polonium: the period found is 140·2 days.—**J. Huggett and G. Chaudron**: The temperatures of magnetic transformations in the system iron–ferric oxide.—**Jolibois and Chassevent**: An apparatus for the thermal analysis of plaster. Details of a calorimetric method which gives the velocity of hydration of plaster of Paris, capable of controlling and classifying commercial products more conveniently than by chemical analysis.—**P. Job**: The cuprammonium ion and its stability. Determinations of the equilibrium constant under varying conditions show that the $Cu(NH_3)_4$ ion is the only ion stable at the ordinary temperature.—**Marcel Delépine**: The oxidation with permanganate of pyridine and the pyridine nucleus. The pyridine nucleus is readily oxidised by acid permanganate solutions, the nitrogen appearing mainly as ammonia with some as nitric acid.—**Marcel Godchot and Pierre Bedos**: The action of organo-magnesium compounds on the oxide of cycloheptene. Cycloheptene oxide is isomerised by the action of CH_3MgI, and the cycloheptanone thus formed (suberone) then reacts with the magnesium compound in the ordinary manner.—**V. Hasenfratz**: The preparation and properties of *l*-arabonic and *l*-ribonic lactones.—**L. Royer**: The regular joining up of cubic salts on mica.—**N. Menchikoff**: The crystalline and volcanic rocks of the centre of the Libyan desert.—**Léon W. Collet and R. Perret**: The geology of the Col d'Anterne and of the Cirque des Fonts (Sixt Alps, Haute-Savoie).—**Albert Baldit**: Magnetic measurements in the south-west of the Central Massif.—**K. Tsukamoto**: The transparency of sea water for the extreme ultra-violet. From experiments on synthetic salt solutions, it is concluded that absorption in the extreme ultra-violet by sea water is due to the presence of small quantities of bromides.—**Pierre Allorge**: The vegetation of the sphagnum peats of Galiad (Spain).—**L. Blaringhem**: The affinities of the wild wheats *Triticum ægilopoides* and *T. monococcum*, demonstrated by their reciprocal hybrids.—**Emile André**: A new and abundant source of trilaurin; the seed of the Mahuba, *Acrodiclidium Mahuba*. Of the family of the Lauraceæ, this seed contains about half its weight of a fat consisting of fairly pure trilaurin.—**H. Lagatu and L. Maume**: Control of the mode of nutrition of a perennial plant (vine) in a given soil receiving a given manure.—**Henri V. Vallois**: The variations of the spinal muscles in the higher primates.—**P. Vignon**: The primitive nervation of the wings of insects and the changes from the original plan in the Orthoptera.—**Jules Amor**: Observations on biological similitude.—**Georges Bourguignon**: Double innervations in the human organism, discovered by pathological and normal electrophysiology and controlled by anatomy.—**Henri Piéron**: The law which connects the surface of the wings with the weight of the individual in the same animal species, and some problems concerning the flight of insects. The wing surface in one species studied (*Libellula sanguinea*) is a linear function of the weight supported.—**G. Lefrou**: The anticoagulating power of certain dyes and organic arsenic compounds.—**Raymond-Hamet**: The point of vascular attack of the ergot alkaloids.—**André Bonot and Théophile Cahn**: The estimation of arginine in pure proteids and tissues by a modified Jansen method.—**E. Roubaud and J. Colas-Belcour**: The action of diastases in determining the eclosion of the egg in the mosquito of yellow fever (*Stegomyia fasciata*).—**Bordier**: General principles and technique of the new treatment of Heine-Medin's disease (infantile paralysis).

Brussels.

Royal Academy of Belgium, April 10, 1926.—**P. Stroobant**: Report of the work done by the National Committee of Astronomy during the year 1925.—**P. Teilhard de Chardin**: Some new mammals from the Belgian Tertiary.

May 4.—**Paul Stroobant**: Note on the discovery of two new minor planets at the Royal Observatory, Uccle.—**A. Demoulin**: Determination of the differential invariants and integral invariants of surfaces for the conformal group.—**A. Demoulin**: The method of the mobile birectangular trihedron and some of its applications.—**A. Demoulin**: The surfaces of Guichard.—**Maurice Nuyens**: The electrodynamics of bodies in motion.—**Constant Lurquin**: The stable algorithms of probability.—**Marc de Hemptinne**: Latent heats of evaporation. The formula proposed by Maurice Prud'homme, $\log L = \log a + n \log (T_c - T)$, in which L is the latent heat of evaporation, T the absolute boiling-point under atmospheric pressure, T_c the critical temperature, and k, a, and n constants, has been compared with experimental data for water, ammonia, pentane, hexane, heptane, octane, carbon tetrachloride, chlorobenzene, fluorenzene, benzene, methyl and ethyl acetates, and methyl alcohol, and shown to be generally applicable.—**W. Mund and J. d'Olieslager**: The kinetics of ozone formation under the action of the α-particles. For a given intensity of irradiation by α-particles, ozone is formed with constant velocity, and at the same time is destroyed with a velocity proportional to its concentration.—**J. Errera**: The polarisation of a medium and its molecular structure. The cases of benzene and cyclohexane. From the experimental work described it is concluded that neither of these hydrocarbons has a permanent dipole.

June 5.—**G. Cesàro**: The formula of some Vesuvian silicates.—**Edm. van Aubel**: The viscosity of liquid chlorine. According to A. J. Batschinski, the specific volume of a normal liquid is a linear function of the fluidity. The experimental data of E. W. R. Steacie and F. M. G. Johnson and of Maurice Jellaton on the viscosity of liquid chlorine are shown to be in agreement with Batschinski's formulæ, except for the temperature, $-33 \cdot 8°$ C., in the neighbourhood of the boiling-point.—**Edm. van Aubel**: The viscosity of fused salts. The viscosities of fused salts (silver nitrate, potassium nitrate, lithium nitrate, sodium nitrate, silver chloride, bromide, and iodide) given by various authors, are all in agreement with Batschinski's formula.—**M. Dehalu**: The movement of the perihelion of mercury deduced from certain laws of gravitation.—**Th. De Donder**: A contribution to the electromagnetic tensor and to the mechanical force of Maxwell-Lorentz.—**A. Demoulin**: The method of the mobile birectangular trihedron and some of its applications.—**Georges Homès**: The ionisation of gases and Saha's equation.—**R. Moens**: An ionisation phenomenon of mercury vapour under low pressure.—**Mlle. A. Binard** and **R. Jeener**: Researches on the morphology of the nervous system of the annelids.—**Henri Fredericq**: Demonstration, by chronaximetric measurements, of the direct bathmotropic action of the extrinsic nerves of the heart.

CALCUTTA.

Asiatic Society of Bengal, Jan. 3.—**J. H. Hutton**: (1) A Naga Hills celt. Description of a unique specimen found at Nichuguard, at the foot of the Naga Hills. It is a stone adze of a new type; the material is fossilised (silicified) wood and it is presumably local in origin. (2) Some megalithic work in the Jaintia Hills. There is some connexion between stone-erecting and water. Megalithic bridges exist near Maput village and across the Um-nyakaneh River. The abandoned European Inspection Bungalow near Syndai is locally attributed to ancient native origin. There are rock-cut tanks near the Am-sorai stream and dolmens and slabs near the Am-lubon River. There is some similarity between the Syntengs and Manipuris and Ao Nagas.—**Jayme Ribeiro**: The caves of Sewri. Bombay is rich in natural cavities and fairly large caves are to be found in the vicinity of this city. The caves as yet discovered skirt the eastern coast line of the Island from Jackeria Bunder to a point a little to the north of the Sewri cemetery, both on the east and west of it. More will no doubt be found, but only to disappear by being covered over with buildings. Detailed descriptions of two of the caves and a general description of the strata are given.

ROME.

Royal National Academy of the Lincei, Dec. 5.—**U. Cisotti**: Uniformisants of non-uniform functions.—**G. Scorza**: Real algebraics united to groups of finite order.—**L. Cambi** and **L. Szegò**: Constitution and absorption spectra of the iron nitrososulphides. The absorption spectra of compounds containing the grouping $-S \cdot Fe \cdot N_2O_2$ or $-S_2O_3 \cdot Fe \cdot N_2O_2$ exhibit certain analogies to those of the ferric compounds $Fe(N_2O_2C_6H_5)_3$ and $Fe(CNS)_3$. In highly dilute solutions the salt $KS_3\ Fe_4(NO)_7$ gives spectra indicating the presence of ferrous iron, just as is the case with $FeSO_4 \cdot NO$. The absorption of light by the above nitrososulphides reveals no characteristic justifying the view that these compounds contain univalent iron.—**L. Rolla** and **L. Fernandes**: A new element: Florentium (atomic number 61). A copy is given of a communication preserved under the seal of the Academy since July 4, 1924, and priority claimed for the discovery and naming of this element.—**F. Sacco**: The question of the age of the ophitiferous argillaceous shales of Appennino.—**B. Finzi**: Relative kinetic energy.—**G. Vranceanu**: Equations of the motion of an anolonomous system.—**U. Barbieri**: Absolute azimuth of Eremo di Cherasco, on the horizon of Mondovi.—**R. Brunetti**: Existence of the element of atomic number 61. Results obtained in 1924 and kept under seal by the Academy since July of that year deal with the absorption spectra of certain specimens of rare earths. From the character and disposition of a discontinuity observed in the spectral region between samarium and neodymium, the presence in the material of the element of atomic number 61, missing from Mendeléeff's table, is presumed.—**R. Brunetti**: Identification of the element with atomic number 61. This element has been identified by means of the *K* spectrum.—**U. Crudeli**: Electro-magnetic fields having the electric (magnetic) field zero at the circumference and the magnetic (electric) field tangential.—**F. De Carli**: Additive products of sulphur dioxide with aromatic hydrocarbons. Note ii. In addition to the compounds recently described, sulphur dioxide forms with ethylbenzene the compounds $C_6H_5 \cdot C_2H_5,\ SO_2$, melting at $-91°$ and $C_6H_5 \cdot C_2H_5,\ 2SO_2$, melting at $-78 \cdot 5°$; with cymene the compounds $CH_3 \cdot C_6H_4 \cdot C_3H_7,\ SO_2$, melting at $-89°$ and $CH_3 \cdot C_6H_4 \cdot C_3H_7,\ 2SO_2$, melting at $-83°$, and with tetraline the compounds $C_{10}H_{12},\ SO_2$, melting at $-58°$, $C_{10}H_{12},\ 2SO_2$ melting at $-66 \cdot 2°$ and $C_{10}H_{12},\ 3SO_2$, melting at $-70°$.—**G. Magnanini**: The Bohr model and the supposed coloration of the ions. Both experimental results and deductions on the basis of Arrhenius's theory show that the dissociated part of a coloured electrolyte has always the same absorption spectrum as the non-dissociated part. This is not in accord with Bohr's theory, so that either electrolytic dissociation is a spontaneous process having nothing in common with true dissociation as produced, for example, by the spark discharge, or the explanations furnished by Bohr's theory with regard to the intimate constitution of matter are inaccurate.—**C. Capelletti**: The bacteroid form and immunity in leguminous plants.

Pontifical Academy of Sciences, Jan. 16.—**Hagen**: Nebula N. G. C. 1193. Opinions contrary to those of Herschel are shown to be erroneous.—**Hagen**: The surface connected with a curve of space.—**Kaas**: A strange case of hypersensibility.—**Carathéodory**: Theory of analytic functions.—**Zanon**: Diatomaceæ of a Venetian peat.—**Borghesani**: A wine from a wild grape of Central America.—**Borghesani**: Treatments of wine for the celebration of mass.—**Neviani**: *Equorfossa Farnesinæ* Nev.—**A. Marotti**: A noteworthy class of permanent plane motions of a perfect liquid.

VIENNA.

Academy of Sciences, Dec. 9.—**L. Schmid** and **G. Bilowitzki**: Communication on insulin. Molecular weight determinations in phenol showed that insulin is highly polymerised in that solvent.—**L. Gröger**: Coloration and luminescence phenomena in Iceland spar after previous treatment with Becquerel rays.—**E. Lohr**: Additions to the continuity theory of Röntgen-ray propagation in crystals.

Dec. 16.—**A. Haas**: The increase of frequency in light-quanta by impact with swiftly moving particles of matter (see NATURE, Feb. 19, p. 296).—**K. Brunner** and **J. Medweth**: The course of the reaction in Brunner's synthesis of triazol.—**W. Gabl** and **O. Schmidegg**: Derivatives of phenyl-dimethyl-triazol.—**H. Hernler** and **F. Matthes**: The nitrification of phenyl- and naphthyl-triazols.—**A. Kieslinger**: Geology and petrography of the Kor Alps.—**F. Heritsch** and **N. Stücker**: The Mürzzuschlag earthquake of July 6, 1926.

Official Publications Received.

British.

Scientific Reports of the Agricultural Research Institute, Pusa (including the Reports of the Imperial Dairy Expert, Physiological Chemist, Government Sugarcane Expert, and Secretary, Sugar Bureau), 1925–26. Pp. vi+212. (Calcutta: Government of India Central Publication Branch.) 2.8 rupees; 4s. 6d.

Agricultural Research Institute, Pusa. Bulletin No. 165: List of Publications on Indian Entomology, 1925. (Compiled by the Imperial Entomologist and the Offg. Imperial Entomologist.) Pp. ii+62+x. (Calcutta: Government of India Central Publication Branch.) 12 annas; 1s. 3d.

Bath Royal Literary and Scientific Institution. Address delivered on July 10th, 1926, by Dr. F. A. Bather on William Smith, 'The Father of English Geology.' Pp. 14+4 plates. (Bath.) 6d.

National Institute of Industrial Psychology. Institute Report No. 1: Occupation Analysis; the Study of Aptitudes and Attainments necessary for Success in different Kinds of Employment. Pp. iv+36. (London.) 2s.

Foreign.

Department of the Interior: Bureau of Education. Bulletin, 1926, No. 6: Personnel and Organization of Schools in the small Cities (2,500 to 10,000 Population, 1924–25). By Prof. Harry S. Ganders. Pp. iv+36. 10 cents. Bulletin, 1926, No. 16: A Handbook of Educational Associations and Foundations in the United States. Pp. iii+82. 15 cents. Bulletin, 1926, No. 17: Record of Current Educational Publications; comprising Publications received by the Bureau of Education to July 1, 1926. Pp. 41. 10 cents. Bulletin, 1926, No. 20: Higher Education; Biennial Survey, 1922–1924. By Arthur J. Klein. Pp. ii+29. 5 cents. (Washington, D.C.: Government Printing Office.)

Department of Commerce: Bureau of Standards. Scientific Papers of the Bureau of Standards, No. 538: Spectral Energy Distribution of the Light emitted by Plants and Animals. By W. W. Coblentz and C. W. Hughes. Pp. 521-534+2 plates. (Washington, D.C.: Government Printing Office.) 10 cents.

University of California Publications in American Archæology and Ethnology. Vol. 23, No. 3: The Emeryville Shellmound; Final Report. By W. Egbert Schenck. Pp. 147-282+plates 36-54. (Berkeley, Cal.: University of California Press; London: Cambridge University Press.) 1 dollar.

Koninklijk Magnetisch en Meteorologisch Observatorium te Batavia. Verhandelingen No. 18: Typen van den Regenval in Nederlandsch-Indie (Rainfall Types in the Netherlands Indies). Door (By) Dr. J. Boerema. Pp. iii+108+2 maps. (Weltevreden.)

Publikationer fra det Danske Meteorologiske Institut. Meddelelser Nr. 6: Om Isforholdene i Danske Farvande Aarene 1861–1906. (Fortsættelse af Meddelelse Nr. 2). Av. C. I. H. Speerschneider. Pp. 88. (København: G. E. C. Gad.)

Société des Nations: League of Nations. Bulletins de l'Institut International de Coopération intellectuelle: Bulletins of the International Institute of Intellectual Co-operation. Bulletin des relations scientifiques: Bulletin for Scientific Relations. 2me année. No. 1, Février. Pp. 187-228. (Paris: Les Presses universitaires de France.) 8 francs.

United States Department of Agriculture. Department Circular 395: The Oriental Peach Moth. By Alvah Peterson and G. J. Haeussler. Pp. 28. (Washington, D.C.: Government Printing Office.) 10 cents.

Proceedings of the United States National Museum. Vol. 70, Art. 8: Some Braconid and Chalcid Flies from Formosa, Parasitic on Aphids. By A. B. Gahan. (No. 2657.) Pp. 7. (Washington, D.C.: Government Printing Office.)

Catalogue of Important Works on Gardening and Botany. (No. 148.) Pp. 40. (London: Dulau and Co., Ltd.)

Catalogue de livres anciens et modernes rares ou curieux relatifs à l'Amérique et les régions polaires. Pp. 48. (Paris: Librairie Adrien-Maisonneuve.)

Wild-Barfield Small Electric Furnaces for Works and Laboratories, and for all Purposes requiring the Accurate Maintenance of High Temperatures. Section H. Pp. 16. (London: Automatic and Electric Furnaces, Ltd.)

Diary of Societies.

SATURDAY, March 5.

Royal Society of Medicine (Otology Section), at 10.30 A.M.

Geologists' Association (in Department of Zoology, University College), at 2.30.—Prof. D. M. S. Watson: Demonstration of Some Early Fossil Vertebrates.

Royal Institution of Great Britain, at 3.—Dr. J. B. McEwen: Beethoven (I).

Institute of British Foundrymen (Lancashire Branch) (at Rochdale), at 6.30.—W. H. Poole: The Foundry Cupola.

Institute of British Foundrymen (Birmingham, Coventry, and West Midlands Branch) (at Engineers' Club, Birmingham), at 6.30.—F. J. Cook: Some Experiences in the Production of Malleable Castings.

Hull Association of Engineers (at Technical College, Hull), at 7.15.—H. Hall: Civil Engineering Experiences in South America.

MONDAY, March 7.

Victoria Institute (at Central Buildings, Westminster), at 4.30.—Prof. T. G. Pinches: The Completed Legend of Bel-Merodach and the Dragon.

Royal Institution of Great Britain, at 5.—General Meeting.

Royal College of Surgeons of England, at 5.—Sir Arthur Keith: The Peoples of the East: Past and Present (3): An Account of the Earliest Sumerians so far Discovered, the Description being based on a Study of Human Remains found at and near Ur of the Chaldees by the Joint Expedition of the British Museum and of the Museum of the University of Pennsylvania under the leadership of Mr. C. Leonard Woolley.

Society of Engineers (at Geological Society), at 5.30.—M. E. Gerard: The Raising of a 1250 ton Coal Bunker after a 7-ft. Subsidence.

Institution of Automobile Engineers (Bristol Centre) (at Merchant Venturers' Technical College, Bristol), at 6.45.—H. R. Ricardo: Some Notes on Petrol-Engine Development.

Institution of Electrical Engineers (Informal Meeting), at 7.—Capt. P. P. Eckersley and others: Discussion.

Glasgow University Alchemists' Club (Annual General Business Meeting), at 7.30.

Aristotelian Society (at University of London Club), at 8.—J. MacMurray: The Place of Experiment in Knowledge.

Society of Chemical Industry (London Section) (at Chemical Society), at 8.—Prof. W. E. S. Turner: Recent Progress in the Glass Industry.

British Psychological Society (Education Section, jointly with General Society) (at Royal Anthropological Institute), at 8.—Prof. J. Piaget: La première année de l'enfant.

Institution of the Rubber Industry (London and District Section) (at Engineers' Club, Coventry Street, W.1), at 8.—P. Dunsheath: Some Electrical Properties of Rubber.

Surveyors' Institution, at 8.—Discussion on Leasehold Reform.

Royal Geographical Society (at Æolian Hall), at 8.30.—Rt. Hon. W. Ormsby-Gore: Some Nigerian Contrasts.

Institute of Chemistry (Manchester and District Section) (at Manchester).—Prof. E. C. C. Baly: Plant Chemistry.

TUESDAY, March 8.

Royal College of Physicians of London, at 5.—Dr. W. F. Dearden: Health Hazards in the Cotton Industry (Milroy Lectures) (2).

Royal Institution of Great Britain, at 5.15.—Prof. J. S. Huxley: Problems of Animal Growth and Development (6).

Institution of Petroleum Technologists (at Royal Society of Arts), at 5.30.—Dr. A. Wade: Two Shallow Oilfields in Texas.

Zoological Society of London, at 5.30.—Prof. E. B. Poulton: Gynandromorphism in Butterflies following Shock to the Pupæ.—Dr. H. H. Scott: Report on the Deaths occurring in the Society's Gardens during the Year 1926.—Prof. D. M. S. Watson: The Reproduction of the Cœlacanth Fish Undina.—Dr. R. Broom: (a) On a New Type of Mammal-like Reptile from the South African Karoo Beds; (b) Some Further Points on the Structure of the Mammalian Basicranial Axes.—Dr. N. S. Lucas, E. M. Hume, and H. H. Smith: On the Breeding of the Common Marmoset (*Hapale jacchus* Linn.) in Captivity when irradiated with Ultra-Violet Rays.

Institution of Civil Engineers, at 6.—A. W. Stonebridge: The Tansa Completion Works for the Water Supply of Bombay.

Institution of Aeronautical Engineers (at Junior Institution of Engineers), at 6.30.—Major H. N. Wylie: Portable Hangars.

Institute of Marine Engineers, at 6.30.—W. F. Rabbidge: The M.A.N. Internal Combustion Engine and other Types.

Institution of Electrical Engineers (Informal Meeting), at 7.—Capt. P. P. Eckersley and others: Discussion on Wireless as a Factor in World Communication.

Institution of Electrical Engineers (North Midland Centre) (at Hotel Metropole, Leeds), at 7.—Dr. W. H. Eccles: Address.

Institution of Electrical Engineers (North-Western Centre) (at Engineers' Club, Manchester), at 7.—J. W. T. Walsh: Illuminating Engineering.—H. T. Harrison: The Problems of Public Lighting by Electricity.

Institution of Electrical Engineers (Scottish Centre) (at North British Station Hotel, Edinburgh), at 7.—L. C. Grant: High-Power Fusible Cut-outs.

Royal Photographic Society of Great Britain, at 7.—Annual General Meeting.

Society of Chemical Industry (Birmingham and Midland Section) (Annual Meeting) (at Birmingham University), at 7.30.—H. W. Rowell: The Commercial Synthetic Resins and their Product (Lecture).

North-East Coast Institution of Engineers and Shipbuilders (at Middlesbrough), at 7.30.—G. B. Butler: From Ironstone to Finished Product.

Quekett Microscopical Club, at 7.30.—S. R. Wycherley: A Fortnight in Sark with a Microscope.

Pharmaceutical Society of Great Britain, at 8.—J. E. Barnard: The Microscope and its Use in Research (Lecture).

Royal Anthropological Institute, at 8.30.—R. Firth: The Exchange of Gifts in Primitive Societies.

Institute of Brewing (London Section) (at Engineers' Club, Coventry Street, W.1).

WEDNESDAY, March 9.

Institute of Metals (Annual General Meeting) (at Institution of Mechanical Engineers), at 10 A.M.—Presidential Address.—Prof. D. Hanson and Grace W. Ford: Investigation of the Effects of Impurities on Copper. Part V. The Effect of Bismuth on Copper.—Prof. D. Hanson and C. B. Marryat: Investigation of the Effects of Impurities on Copper. Part III. The Effect of Arsenic on Copper. Part IV. The Effect of Arsenic plus Oxygen on Copper.—C. Blazey: Brittleness in Arsenical Copper.—At 2.—D. F. Campbell: Electric Furnaces in Non-Ferrous Metallurgy, and a General Discussion on Electric Furnaces in Non-Ferrous Metallurgy.

INSTITUTION OF CHEMICAL ENGINEERS (Conference) (at Chemical Society), at 5.—W. C. Freeman: The Production of Dissolved Acetylene and its Application to Lead Burning.—S. J. Tungay: Lead as a Constructional Material in Chemical Engineering.—At 8.—Dr. H. J. Bush and A. Grounds: The Function of the Schmiedel Box in Sulphuric Acid Manufacture.—W. G. Mills: Some Improvements in Chamber Sulphuric Acid Plant.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: The Peoples of the East: Past and Present (4). The Racial Characters of Sumerians and Babylonians and their Relationship to other Peoples.

INSTITUTION OF CIVIL ENGINEERS (Informal Meeting), at 6.—A. H. Douglas: Traverse Surveys.

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at Birmingham University), at 7.—J. W. T. Walsh: Illuminating Engineering.—H. T. Harrison: The Problems of Public Lighting by Electricity.

ELECTRICAL ASSOCIATION FOR WOMEN (at E.L.M.A. Lighting Service Bureau, Strand), at 7.—Simple Household Repairs—Fuses, Lampholders, Bells, etc.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section) (at Bolbec Hall, Newcastle-upon-Tyne), at 7.15.—J. H. Frith: Grinding.

ROYAL SOCIETY OF ARTS, at 8.—Dr. E. W. Smith: The Utilisation of Gas Coke.

MEDICAL SOCIETY OF LONDON, at 9.—D. J. Armour: The Surgery of the Spinal Cord and Membranes (Lettsomian Lectures) (2).

THURSDAY, MARCH 10.

INSTITUTE OF METALS (Annual General Meeting) (at Institution of Mechanical Engineers), at 10 A.M.—R. Genders: The Penetration of Mild Steel by Brazing Solder and other Metals.—J. H. Miller: The Penetration of Brass by Tin and Solder, with a Few Notes on the Copper-Tin Equilibrium Diagram.—H. J. Hartley: The Attack of Molten Metals on Certain Non-Ferrous Metals and Alloys.—H. Moore and S. Beckinsale: Notes on the Manufacture and Properties of Hair Springs.—F. Hargreaves: (*a*) The Application of Strain Methods to the Investigation of the Structure of Eutectic Alloys; (*b*) Note on the Crystallisation of the Lead-Tin Eutectic.—At 2.—J. D. Grogan: The Influence of Calcium on Aluminium containing Silicon. With an Appendix on The Estimation of Calcium in Aluminium Alloys, by P. G. Ward.—M. Hansen: The Magnesium-Rich Magnesium-Copper Alloys.—R. Genders: The Mechanism of Inverse Segregation in Alloys. With an Appendix on The Accurate Determination of Copper in Bronze by Electrolysis, by R. A. F. Hammond.—Prof. Kôtaro Honda and Prof. Hikozo Endo: Magnetic Analysis as a Means of Studying the Structure of Non-Magnetic Alloys.—Prof. B. W. Holman: An Etching Reagent for Copper.—Dr. J. Newton Friend and W. E. Thorneycroft: (*a*) Examination of a Fifteenth Century Brass; (*b*) Note on the Silver Contents of Roman Lead from Folkestone and Richboro Castle.

ROYAL SOCIETY, at 4.30.—A. Levin and J. Wyman: The Viscous Elastic Properties of Muscle.—A. Hynd: The Action of Glucosone on Normal Animals (Mice) and its Possible Significance in Metabolism.—Dr. F. W. R. Brambell and Dr. A. S. Parkes: Changes in the Ovary of the Mouse following Exposure to X-Rays.—Dr. A. S. Parkes, Una Fielding, and Dr. F. W. R. Brambell: Ovarian Regeneration in the Mouse after Complete Double Ovariotomy.—A. Walton: The Relation between 'Density' of Sperm-Suspension and Fertility as determined by Artificial Insemination of Rabbits.

INSTITUTION OF CHEMICAL ENGINEERS (Conference) (at Chemical Society), at 5.—B. D. Porritt: Rubber as a Constructional Material in Chemical Engineering.—At 8.—Prof. F. C. Lea: The Effect of Heat on some of the Properties of Metals.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science), at 5.—Dr. G. M. B. Dobson: The Measurement of the Absorption Coefficients of Light Filters.—Ibbs and Underwood: A Comparison of the Behaviour in Thermal Diffusion of Nitrogen and Carbon Monoxide, and of Nitrous Oxide and Carbon Dioxide.—R. R. Nimmo: The Relighting of a Neon Lamp when Momentarily Extinguished at Voltages below the Striking Potential.—D. B. Deodhar: The Electrification of Dust Clouds.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Prof. F. R. Fraser: Cardiac Dyspnoea (Goulstonian Lectures) (1).

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Prof. J. Garstang: The Progress of Hittite Studies (3).

SOUTH LONDON ENTOMOLOGICAL AND NATURAL HISTORY SOCIETY (at Hibernia Chambers, London Bridge), at 7.

INSTITUTION OF ELECTRICAL ENGINEERS (Dundee Sub-Centre) (at University College, Dundee), at 7.30.—G. H. Taylor: The Jubilee Year of the Telephone.

OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7.30.—B. Graves: Microscopy of the Living Eye.

ROYAL SOCIETY OF MEDICINE (Neurology Section) (at National Hospital, Queen Square, W.C.1), at 8.

HARVEIAN SOCIETY (at Paddington Town Hall), at 8.30.—Sir Berkeley Moynihan: Diverticula of the Alimentary Canal (Harveian Lecture).

OIL AND COLOUR CHEMISTS' ASSOCIATION.

INSTITUTION OF THE RUBBER INDUSTRY (Manchester Section) (at Manchester).—N. Blond: Difficulties of Rubber Proofed Garment Manufacture.

FRIDAY, MARCH 11.

INSTITUTION OF CHEMICAL ENGINEERS (Annual Corporate Meeting) (at Hotel Victoria), at 12.—Sir Frederic Nathan: Some Industrial Developments and the Chemical Engineer (Presidential Address).—At 2.30.—F. H. Rogers: The Cross Cracking Process and Plant.

DIESEL ENGINE USERS' ASSOCIATION (at Caxton Hall), at 3.—P. A. Holliday: High-Revolution Oil Engines.

ROYAL SOCIETY OF ARTS (Indian Meeting), at 4.30.—R. Mather: The Iron and Steel Industry in India.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Prof. F. Schlesinger: Astronomical Photography of Precision (George Darwin Lecture).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: The Peoples of the East: Past and Present (5). The People of Egypt, Past and Present, and their Position in a Classificatory System.

MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society), at 6.

INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section, jointly with Students' Sections of Institutions of Civil and Mechanical Engineers) (at Institution of Electrical Engineers), at 6.15.—A. C. Price: Patents.

INSTITUTE OF MARINE ENGINEERS, at 6.30.—Annual Meeting.

INSTITUTION OF AUTOMOBILE ENGINEERS (North of England Centre) (at The Temple, Dale Street, Liverpool), at 7.—A. F. Evans: Ships' Lifeboat Motors.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—A chat with Mr. B. Lemere on Architectural Photography.

INSTITUTE OF METALS (Swansea Local Section) (at University College, Swansea), at 7.15.—Dr. F. Johnson: The Influence of Oxygen on Copper and other Non-Ferrous Metals.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—J. Wolstenholme: The Design, Construction, and Operation of the Cupola.

INSTITUTE OF METALS (Sheffield Local Section) (at Sheffield University), at 7.30.—L. Lubbock: Oil Fired Furnaces.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Dr. G. Macdonald: The Wall of Hadrian.

OIL AND COLOUR CHEMISTS' ASSOCIATION (Manchester Section) (at Manchester).—Dr. S. Smith: Cellulose Ester Varnishes: their Manufacture, Properties, and Application.

SATURDAY, MARCH 12.

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (South-Western District) (at Bath), at 12.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr. J. B. McEwen: Beethoven (3).

PUBLIC LECTURES.

SATURDAY, MARCH 5.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—H. Harcourt: Some Poisonous Snakes of India.

SUNDAY, MARCH 6.

GUILDHOUSE (Eccleston Square), at 3.30.—Dr. C. Delisle Burns: Experimental Religion.

MONDAY, MARCH 7.

KING'S COLLEGE FOR WOMEN (Household and Social Science Department), at 5.15.—Mrs. Rackham: Justice and the Citizen.

UNIVERSITY OF LEEDS, at 5.15.—Dr. T. Slater Price: Photographic Sensitivity.—At 8.15.—Sir Henry Hadow: Beethoven.

TUESDAY, MARCH 8.

SURVEYORS' INSTITUTION, at 5.30.—Major G. H. Scott: The Development of Airship Transport (Lecture).

WEDNESDAY, MARCH 9.

UNIVERSITY COLLEGE, at 5.30.—Sir William Schooling: Photography of Documents: Object and Methods.

THURSDAY, MARCH 10.

UNIVERSITY OF LIVERPOOL, at 4.—Prof. V. Putti: New Conceptions in the Pathogenesis and Treatment of Sciatica (Lady Jones Lecture).

UNIVERSITY COLLEGE, at 5.—Prof. E. A. Gardner: History of Ancient Sculpture.

ROYAL SOCIETY OF MEDICINE, at 5.15.—Dr. C. F. Coombs: Rheumatism—its Causes and Prevention: The Chronic Rheumatic Diseases (Chadwick Lecture).

KING'S COLLEGE, at 5.30.—Prof. C. G. Seligman: The Mind: Anthropology.

SATURDAY, MARCH 12.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss M. A. Murray: Trading in Ancient Egypt.

SUNDAY, MARCH 13.

GUILDHOUSE (Eccleston Square), at 3.30.—Major W. Tudor Pole: Universalism in Religion, with special reference to the Bahai Faith.

CONGRESSES.

APRIL 20 TO 24.

JOURNÉES MÉDICALES MARSEILLAISES ET COLONIALES (at Marseilles).—Prof. Cantacuzène: The Rôle of the Streptococcus in the Etiology of Scarlet Fever.—Dr. Mayer: Recent Advances in the Treatment of Cancer.—Prof. Ottolenghi: Malaria.—Dr. N. Bernard: Beri-beri.—Prof. Imbert: Bone-grafting.

APRIL 25 TO 28.

GERMAN SOCIETY FOR INTERNAL MEDICINE (at Wiesbaden).—Discussions on Psychotherapy, introduced by Gaupp and Fleischmann; Results of Recent Functional Investigations of the Stomach and Duodenum, introduced by G. Katsch.—A joint meeting with the German Röntgen Society will be held on April 28, with a discussion on the Significance of Röntgen-ray Examination of the Lungs and Mediastinum for Internal Medicine (excluding Tuberculosis), introduced by Dietlen, Assmann, Haenisch and Lorey, and Fleischner.

SATURDAY, MARCH 12, 1927.

Pestalozzi and the Teaching of Science.

JOHANN HEINRICH PESTALOZZI died at Brugg, Switzerland, on Feb. 17, 1827; and in the hundred years which have passed since then, a great change has taken place in educational thought and practice. Especially is this so in the province of school science, a growth almost entirely of the latter part of the nineteenth century. But as with all growths, we must search for the roots in the history of a far earlier period than this; and then we discover what science teachers owe to the pioneers of old, one of whom, Pestalozzi, will always hold an honoured place.

During the Middle Ages, when Aristotelian doctrines dominated intellectual thought and the grammar schools in England were precluded by their statutes from teaching any but grammatical subjects, there were already many people alive to the fact that a knowledge of science would be of advantage to the rising generation. They were not, however, thinking of science as we understand it to-day; all they advocated was a study of the scientific works of the classical authors, and by the middle of the seventeenth century a few, but very few, schoolmasters endeavoured to emphasise books of this nature.

Following the rise of modern science, and about the time of the foundation of the Royal Society (1662), a few pioneers urged a reform of the school curriculum in the direction of science teaching. But whether it was Comenius in his wide embracing encyclopædic fashion urging complete reform, or Milton and Cowley advocating a closer study of scientific Latin and Greek books, or Hartlib and Petty emphasising the need of school science of a practical nature, little success attended their labours. Their schemes were all premature; the English grammar schools were not allowed by law to teach science until 1840.

A hundred years after the beginning of the scientific movement came Rousseau, with his vigorous revolutionary doctrines, bent on making his Émile a model youth. The old order was to be swept away and Émile's education was to proceed on novel lines. Amongst other things he must learn science, not book science, but practical, everyday science. No pedant was to teach him, he must teach himself: "Let him not be taught science, let him discover it." No book for Émile but that of the world, for books "only teach us to talk about things we know nothing about." Wordiness in education must disappear, and in its place come things, a first-hand acquaintance with things, so bringing into use the boy's powers of observation, reasoning, and invention.

At the time, in 1762, when "Émile" was published, Pestalozzi was a student at the University of Zurich. He was enraptured with the book, and became ensnared in the revolutionary ideas of his hero Abandoning in turn his course of study for the ministry and for the law, he turned to farming, where his idealism was rewarded with bankruptcy. He then became schoolmaster, a profession he was to follow until his death in 1827.

In this short article we are not concerned with his general views on teaching or with the methods he devised or adopted. It is enough to say that he believed that the true basis of knowledge was sensory experience, and that education should be based on personal, first-hand observation. Out of this grew the familiar object lessons of the nineteenth century, and these are of great significance in the history of science teaching. For during them much scientific information was imparted to the children, since Pestalozzi and his numerous followers took for the subject matter familiar and interesting objects. The pupils learnt to look at things more closely, to examine plants, animals, and inanimate objects. Pestalozzi, it may be recalled, had had experience in farming, and it seems highly probable that in the lessons he himself gave, agricultural topics would frequently be mentioned. Occasionally excursions were made into the surrounding districts, when, under the supervision of the teacher, many interesting titbits of natural history were learnt. But unfortunately this science, if such it can be termed, was taught generally without plan and was of a haphazard nature. It was largely of the demonstrative type, where the attention of the child was directed to some particular part or property of the object, the name of which, when given by the teacher, was repeated aloud and memorised. Such lessons had for their chief function the teaching of words, not science.

In addition, however, to the smattering of scientific information which he gave in this manner, Pestalozzi included physics and chemistry in the curriculum of the school at Munchunbuchsee, and, in the "Report to Parents," special mention was made of science teaching, thus:

> "We are also trying at the same time to organise the teaching of experimental science. So far we have demonstrated to the boys the principal facts concerning Electricity and Magnetism and the behaviour of certain gases. We are, in this connection, trying to establish a satisfactory course of instruction in the language of physical science. A local doctor gives weekly lessons in this direction to the older children with the aid of excellent apparatus in his possession."

Natural history was also taught, for, as he pointed out, almost every child is sure to be familiar with "half a dozen mammals, and as many birds, fishes, insects, amphibians, and worms." In short, he endeavoured to connect the course with the things the boys could see around them, such as the behaviour and structure of the common animals and plants.

All this Pestalozzi was doing, whilst in England and most other countries little, if any, attention was being paid to science in the schools. It is rather significant that many schools, when first introducing science, did so in a similar manner. For example, Dr. Arnold, of Rugby, persuaded the boys to collect specimens of rock, etc., from their neighbourhood to form a science museum, and his successor, Dr. Tait, invited a local physician to give lessons similar to these suggested by Pestalozzi.

The latter had no misgivings on how science should be taught, as the following extract from "How Gertrude Teaches Her Children" shows:

> "All science teaching that is dictated, explained, analysed by men who have not learnt to think and speak in accordance with the laws of Nature, all science teaching of which the definitions are forced, as if by magic, into the minds of children, like a *Deus ex machina*, or rather are blown into their ears by a stage prompter, so far as it does, this must necessarily sink into a miserable burlesque of education."

Pestalozzi's influence on science teaching rests, however, on his object lessons, for they were widely imitated in England, largely owing to Dr. Mayo and his sister. After Dr. Mayo's return from visiting Pestalozzi he opened a school at Epsom and later at Cheam, and in time the Home and Colonial Infant School Society's training college resulted. Here intending teachers were trained to give these object lessons. Further, the two Mayos published books on methods of teaching, the most important for our present purpose being Miss Mayo's "Lessons on Objects." In it were given typical object lessons on numerous scientific subjects, and these served as models to numerous teachers. Lessons of this type became very common in England, especially in the elementary schools, and for many years, in fact until the introduction of Lowe's Revised Code in 1861, they were the only means by which children at such schools were brought into touch with science. But the lessons departed from the model of Pestalozzi, and readers of Dickens will recall the type of lesson Bitzer of "Hard Times" had to endure with his "Quadruped, graminivorous forty teeth, etc.," or the one Nicholas Nickleby caught Squeers giving.

Pestalozzi's influence was not confined to the elementary schools, however, and many secondary schools taught object lessons often with the idea of giving scientific information. Thus, from its foundation in 1832, University College School, London, made use of Miss Mayo's book on "Lessons on Objects," but not for long, since it was found, as Dickens saw later, that these lessons tended to degenerate into a mere explanation of hard words, and hence they were soon discontinued at this school.

Yet though Pestalozzi did little to establish modern school science—the science of his day was not sufficiently organised to serve as a school subject, whilst he himself was chiefly interested in young children—his name must be revered by science teachers because of his patient research into better methods of teaching.

The Industrial Revolution.

Health, Wealth and Population in the Early Days of the Industrial Revolution. By M. C. Buer. Pp. xi + 290. (London: G. Routledge and Sons, Ltd., 1926.) 10s. 6d. net.

THE author of this book is lecturer on economics in the University of Reading. The work is one which, in our opinion, is of first-class importance, written in a most interesting style, and we heartily commend it to all our readers. It is difficult within the compass of a review to give an adequate idea of the value of its contents. It deals with a subject which has caused acute controversy, and still awakens intense emotion in the minds of many of our countrymen—namely, the so-called industrial revolution. Although the author approves of the use of this term, and indeed states that the industrial revolution was of such magnitude as to dwarf all political revolutions, yet we think that the word revolution is misapplied in this case. This word has always been held to denote a violent upheaval and overturning of the social order by insurgence from within; but the industrial revolution was merely an extremely rapid evolution due to purely natural causes, as the author convincingly shows; and it had declared itself, shown all its characteristic features, and accomplished much of its course before any political change took place at all.

The popular conception of this change, which still figures largely in Socialist literature (we remember hearing it expounded with great vehemence by the late Mr. Hyndman in 1890), was that it involved the seizing of the common land of the poorer people by the landlords, whilst the dispossessed were then transformed from freeholders into tenants-at-will or driven into the towns, where they were 'exploited' at starvation pay by greedy manufacturers. It was, so far as we can recollect, Dean Inge who first forced on public attention the fact that this change was accompanied by an enormous and rapid increase in our population. The Dean's estimate was that the population of England had increased by 30 per cent. between 1700 and 1800, and by 300 per cent. between 1800 and 1900; it is with the causes and time of beginning of this increase that our author first sets herself to deal.

The first census of England was made in 1801, but various sources of information exist from which fairly trustworthy estimates of the population at earlier dates can be made. The author weighs the evidence, and comes to the conclusion that at the beginning of the eighteenth century the population of England was 5¼ millions; that it decreased during the first decade and then began to rise, and that it showed a net increase of one million by 1750, but that between 1750 and 1820 the population doubled itself. The rapid increase therefore began long before the invention of the steam engine, and before the expansion of manufacturing industries. It must obviously have been due either to immigration, or to an increase in the fertility of marriage, or to a fall in the death-rate. The author proves that the last was the real cause, and that it was not an increase on the longevity of adults which took place, *but a fall in the infantile death-rate*. She goes on to show that amongst primitive peoples population is regulated by an appalling wastage of child life. Persia, for example, is a country without motors, railways, or manufactures; there is widespread peasant proprietorship and few large towns—yet in some districts 85 per cent. of the children die before attaining the age of ten years, and in other districts only one child in ten attains maturity. In this, man resembles the lower animals, for the greater part of 'natural selection' takes place at the expense of the young.

Now in the sixteenth, seventeenth, and eighteenth centuries, but especially during the first two, England was ravaged by diseases formerly supposed to be tropical. The exact nature of some of these was obscure, because distinct diseases were confounded together under the name of plague, but bubonic plague, typhus, typhoid, dysentery, malaria (ague), and above all, smallpox, were rampant. Smallpox attacked chiefly the young, and few children escaped it. About the middle of the eighteenth century, inoculation as a remedy was introduced, to be followed soon afterwards by vaccination. The author shows that inoculation was in most cases an effective and not very dangerous remedy, since it was performed with an attenuated virus, and in one respect it excelled vaccination, because it was never necessary to repeat it.

Thus the main reason for the increase was the gradual improvement of medical science, but this was coupled with the better development of agriculture and a regular and more nutritious supply of food. Food began to be grown for trading with other districts, not merely for the support of a particular district; this was rendered possible by the development of better roads. The author throws scorn on the idea that the medieval peasant proprietor lived under idyllic conditions. He was miserably housed, and he worked for unthinkable hours for a pittance. When the harvest failed there was no means of bringing food from elsewhere, and the peasant starved, or died from diseases which attacked him owing to his weakened condition brought on by eating rotten grain. One of the diseases which decimated the population was scurvy. Since there was no means of feeding cattle during the winter, the majority were slaughtered every autumn and their flesh salted. The stringency of the game laws is said to have been due to the determination of the feudal lords to avert scurvy by having fresh meat during the winter, so they alone were allowed to hunt game and to keep pigeons. But in the middle of the eighteenth century root crops were introduced from Holland, and thereafter cattle were kept alive during the winter.

The common on which the peasant had grazing rights and from which he collected firewood was unenclosed waste. The author gives a vivid picture of how incredibly large and unproductive this waste was when enclosure began. Agriculture could only be improved by bringing a large part of it under cultivation, and there is no evidence to show that this enclosure was detrimental to the peasant. For when really productive farming began there was regular employment for more men, and a comparison of villages in districts with and without enclosure shows that the population increased faster in the former than in the latter. What the peasant hated was a change in his habits; he preferred to starve under old conditions to which he was accustomed rather than to prosper under the new ones.

The author emphasises the fact that during the eighteenth century, though there was little political liberty as embodied in the right to vote, there was abundant personal and intellectual liberty. To the freedom of initiative, to the prevalence of the doctrine of laissez-faire—in a word, to private enterprise—she attributes the major part of the influences which produced modern England.

At the beginning of the century Northumberland was as wild and unenclosed as the backwoods of Canada, and the enterprising farmers who settled in its valleys, cleared the timber, and brought the ground under cultivation were as truly adventurous pioneers as the merchant adventurers of Queen Elizabeth.

Of course, as the steam engine came into use our manufacturing capacity increased enormously, and there was a steady drift into the towns which has continued ever since. A favourite theory has been that the peasants were lured from their healthy homes in the country into the slums of the towns, where they rotted and died. Now the author shows that the medieval city was in reality a festering sore. To contemporary writers cities were known as devourers of population. Our cathedrals, so beloved by the medievally-minded amongst us, arose in the midst of narrow, unspeakably dirty lanes from which air and light were shut out by overhanging upper stories, with no sewers except an open drain in the middle of the street, into which all rubbish, including human excreta, was flung from the windows. Herds of pigs wandered about fattening on this garbage, and proposals of the rich to pave the streets and remove the rubbish were resented by the poor as an invasion of their privileges. Truly the medieval circle of ideas which the reactionaries would restore if they could, was one of dirt and primitive superstition. But in the eighteenth century, when the drift to the towns began, advancing medical science had begun to discover the necessity for a better water supply; the streets were wider and better paved, and the garbage was removed. Far from perfect as the habitations of the work-people undoubtedly were, they were better than the dwellings they left behind in the country, and population grew in the towns by increase of births over deaths.

The myth that the workmen were 'exploited' by the payment of scandalously low wages is also exploded by the author. As she says, there never was a time when native talent and initiative amongst the workmen had greater opportunities. Early machinery was costly, wasteful, and constantly breaking down, and workmen with skill, common sense, and adaptability could practically demand their own price. Those who got the minimum wage and deserved no more were those who were only fit for routine operations. Just as daring private enterprise built up our agriculture, so it founded our manufactures. On it all England's greatness is founded, and by it, though sorely hampered and embarrassed, we still are borne.

The perusal of this book leaves us with some curious reflections. This unspeakably filthy medieval society from which we have slowly emerged succeeded to a Roman civilisation—a civilisation with paved roads carved with superb engineering across hill and dale; with properly constructed sewers, and with a plentiful supply of pure water carried on wonderful aqueducts. Houses were provided with 'central heating' on much the same plan as that now to be adopted in Liverpool Cathedral, and above all, with properly constructed baths. This civilisation can be traced through Rome to Greece and back to Crete, and possibly eventually to Egypt.

Yet this age-long civilisation, which must have appeared to its contemporaries as securely founded and permanent as the orbit of Nature itself, succumbed to the attacks of northern barbarians, and not until the middle of the nineteenth century did we reach the same level as that achieved by Rome. Washing was eschewed in the Middle Ages as a heathen luxury. So late as 1801 a London doctor stated that his patients amongst 'ladies and gentlemen' washed their hands every day, but did not wash their bodies from year to year. The Anglo-Saxon St. Dunstan is said to have given proof of his holiness by the fact that when he shook his sleeves as he sat at board, 'maggots' escaped from them.

The Mediterranean civilisation once penetrated to the south of Africa. Like the Roman civilisation in Britain, it was overwhelmed by barbarians, and its remains, overbuilt by the kraals of Kaffirs, are to be seen until this day. Our twentieth-century civilisation, if the private enterprise which upholds it is undermined, might suffer a like fate.

E. W. M.

The Empty Quarter.

In Unknown Arabia. By Major R. E. Cheesman. Pp. xx + 447 + 32 plates. (London: Macmillan and Co., Ltd., 1926.) 25s. net.

OF the excellence of Major Cheesman's journey into the deserts of eastern Arabia there can be no question. He travelled down the Persian Gulf from Basra to Bahrain, and from there to the little port of Oqair, on the Arabian coast; there he met camels, sent down for him by the ruler of eastern Arabia, Abdul Aziz ibn Saud, whom he had already met, and to whom he carried a personal letter from Sir Percy Cox. The camels took him, his baggage, and his Baghdadi servant to Hufuf, an oasis which has already been visited by several European travellers. The purpose of the expedition was to collect mammals and birds, and, where necessary, to fix the position of places astronomically, and to make compass traverses when passing over unmapped routes; the traveller's purpose was to work his way south from Hufuf towards the empty quarter of Arabia, unvisited by Europeans, unknown to most Arabs, and only recently brought under the suzerainty of the conquering ibn Saud, leader of the Wahhabis.

Cheesman was delayed nearly three months in Hufuf in mid-winter; he occupied his time collecting the fauna and making a map as unobtrusively as possible, but he was handicapped by the season, for the resident birds were not breeding, and there was no through migration; the insects were presumably hibernating, if we may judge from his scanty collection and from what we know of their behaviour at the same season in Mesopotamia.

At length, on February 8, he left Hufuf and travelled 150 miles south over unknown country, most of it hard desert of an extreme type, until he reached the wells of Jabrin. He is the first European to see the Al Murra Arabs at home; he has brought back a route map, and established the position of the Wadi Sahba, which is now dry at all seasons, but formerly carried water from the highlands of western Arabia right across the peninsula to the Persian Gulf. He has also brought home a good collection of birds and mammals, and of observations on their habits, and a number of specimens of insects, plants, and rocks.

So much for the journey, already described in the *Geographical Journal*. The present book is delightful when it describes the author's observations on bird, beast, or man, and the conclusions which follow immediately from them. There is, for example, an excellent chapter on the water supplies of desert animals, though we think that the author is too much inclined to look for actual water in the form of dew, and that he does not realise the high proportion of water which is held in fragments of dry vegetation. There are also some most interesting notes on gerbilles of the genus Meriones, which prove to be diurnal, and not nocturnal like other gerbilles. We think that the author could have written a book of more permanent value had he included a general account of Nature in Mesopotamia and the islands of the Persian Gulf; he knows more about these countries than any other field naturalist, and he has wandered over them in all directions and at all seasons, collecting and observing. The raw materials for such a study are available in a long series of systematic papers by various specialists in the *Jour. Bombay Nat. Hist. Society*. The present book contains no reference to any of the author's previous travels, except a reprint of an account of a journey along the shores of the Gulf from Oqair to Salwa, and for this reason is a little unsatisfying. So far as the last journey is concerned, the unknown country covered was between Hufuf and Jabrin, and that journey only occupied a fortnight; the same featureless track was covered twice, and a general account of it would be easier to read than the transcript of diary which is given. But even as it stands the book is full of life and vigour and observation, and it makes delightful reading.

When the author gets away from his own observations, however, his zoology becomes surprisingly 'loose.' One may quote his own italicised sentence: "*I think the development of a colour as evidenced most clearly in a subspecies is the result of an influence which I will call subspecific desire, operating through generations of that subspecies, for that particular tone.*" It is clear from the context that he does, in fact, attribute the colour of animals to volition, and that the exercise of the will is thought to be most potent when the bird is nesting, except that predatory species do their 'wishing' when they are stalking their prey.

With regard to protective coloration, the author is strictly orthodox, so much so that he brings forward no fresh arguments in favour of the theory; instead of doing so he talks in general about willow grouse, and mallard, and desert birds, and trout, and lizards, and nightjars (which almost shut their eyes, because they know how conspicuous the eye would otherwise be!). Every one admits that the majority of desert animals, in the widest sense of the word, are coloured so that they resemble the soil on which they are found; in some cases the degree of resemblance is very high, in many much less so; but the theory that this similarity of colour is *protective* is not generally accepted nowadays, because it does not appear to cover more than a fraction of the facts. It is difficult to apply it to the strictly nocturnal animals, and still more difficult to fit it to the subterranean pocket gophers of California and Arizona, and other subterranean mammals and reptiles, many of which exhibit a high degree of resemblance to the soil in which they live. Moreover, if the facts are faced without prejudice, it will be found that a proportion of diurnal desert creatures are black, and this is true in the Old World, America, and Australia; examples occur in birds, and grasshoppers, beetles, flies, and other creatures.

The devout believer in protective coloration will tell us that none of these black creatures needs protection, and that explanation is enough for him; but those who are inquisitive, perhaps agnostic, may reasonably ask why all the creatures which do not need 'protection' should agree to wear black. Even among the facts recorded by Cheesman himself, one can find examples of animals to which the theory of protective coloration cannot be applied. In Arabia, and in many parts of the Old and New World deserts, the bats are much more sand-coloured than their relatives in other climates; moreover, this tendency, which is observable in the less extreme deserts—for example, Mesopotamia—is increased in the intense climate of Hufuf and other similar places. It appears that nothing but an act of faith could carry the true believer over such an obstacle as this, for we can scarcely suppose that a pale bat is protected from a (hypothetical) owl, or that its paleness assists it in pursuing moths (also 'protected') by moonlight.

We understand that the author left for Abyssinia before the book passed through the press, but that does not explain the multitude of inaccuracies which it contains. He was probably wise to adopt a simple system of transliteration from Arabic, suited to the general reader, but his use of it is quite inconsistent. For example, he writes *suq* and *booma*, though both have the same long *u* in the original tongue; on the other hand, he writes *suq* and *burr*, using the same English vowel to represent different sounds. He commonly transliterates the Arabic letter *Khe* by *Kh*, consistently with general usage, but he also uses *k* in 'Jebel Akdhar,' and *h* in 'Hashm.' "The ibn Shaikh" is an unnatural mongrel between the English "The

Shaikh's Son," and the Arabic "Ibn esh Shaikh." One gathers that when Cheesman bade farewell to the Amir at Jabrin, both were so much overcome that they forgot their grammar; one said "we am so pleased you came," and the other chorussed, "I are so pleased to have met you." Neither 'Brinjal' nor 'Jird' are words known to the educated English reader, and as one is Hindustani and the other Persian, there seems no justification for their use here, particularly as English equivalents of both are available.

The illustrations from the author's photographs are admirable, and they serve to show what excellent results may be obtained with a minimum of apparatus and trouble. They were all obtained with a quarter-plate Kodak, and the films were developed four months after they were taken, in England. The scientific results of the expedition have been dealt with by specialists, and their accounts are all reprinted as appendices; the result is that all that is known of the fauna of this part of the world is contained in this one volume. There is an adequate index and an excellent map, reprinted from the *Geographical Journal.*

PATRICK A. BUXTON.

British Optical Science and Industry.

(1) *Proceedings of the Optical Convention, 1926.* Part 1. Pp. x+491+v+26 plates. Part 2. Pp. viii+493-1051+v+23 plates. (London: The Optical Convention, 1 Lowther Gardens, 1926.) 2 vols., 60*s.* net.

(2) *The Optical Convention, 1926. Catalogue of Optical and General Scientific Instruments.* Pp. x+326. (London: The Optical Convention, 1 Lowther Gardens, 1926.) 6*s.* net.

(1) TWENTY-TWO years ago the first Optical Convention, defined as a conference of opticians "to discuss questions of interest and to promote the general welfare of the Trade," was held in London under the presidency of Sir Richard Glazebrook. It amply fulfilled the expectations of those members of the Optical Society whose prescient minds foresaw the advantages that might accrue to the science and practice of optics.

Seven years later, Prof. Silvanus P. Thompson, the president of the second Convention, held in 1912, in his address to the members declared: "We are met here to exchange views, to deliberate, to discuss, to learn from one another and from the material objects we have been able to bring together in an Optical Exhibition, anything and everything which can stimulate our thoughts, widen our information, or concentrate or harmonise our activities in matters optical."

After a further lapse of fourteen years the third Convention, presided over by Sir Frank Dyson, has recently been held. During that period of fourteen years the optical industry has experienced an extraordinary expansion followed by prolonged post-War depression. But however subdued the present state of the industry may be, there is no apparent abatement of the interest in optics. This is manifested by the two large volumes which embody the proceedings of the Convention. Containing as they do more than ninety papers, some of them miniature treatises, dealing with every aspect, they constitute the largest and most comprehensive addition to the literature of practical and theoretical optics that has ever been made at one time.

Surveying, and particularly that latest development, aerial surveying, forms the subject of fourteen papers. There are ten devoted to visual optics and eleven to photometry. Optical computation takes a prominent place, but only the geometrical aspects of the question have received much attention: practical trigonometrical methods such as are used by the manufacturer still receive little consideration from the mathematicians. For the first time there are included several excellent historical papers.

Since the date of the second Convention the foundations of optics have been overturned and the builders still lack some necessary material for their reconstruction. Only one paper on this basic subject is included. There is also only one paper—fortunately an authoritative one—which deals with that one-time popular instrument, the microscope.

So large a number of papers delivered in so short a time has resulted in a discussion of unduly limited extent; it amounts to about 13 per cent. of the material. In 1905 there was a 22 per cent. discussion, and in 1912, 18 per cent.

The index is scarcely adequate. The illustrations are generally good, but the cover is unattractive. In this respect it would be well in future to depart from the bad example of the 1905 *Proceedings.*

(2) This catalogue is no mere enumeration of the instruments of British origin exhibited at the Optical Convention of 1926. It records the important advancement that has been made by the optical industry since the date of the last Convention; it is a record of advancement that is remarkable when it is realised that all products of purely war character have been excluded. It also

serves as an index to which future progress will be referred.

More than sixty British firms who participated in the exhibition have contributed descriptions of the instruments and optical materials produced or supplied by them. These descriptions are devoid of salesmanship claims and are of special interest, as they express the essentially practical opinions of the manufacturers themselves.

Instruments are well classified under seventeen groups, of which by far the most extensive is that devoted to the microscope, which receives so little attention in the *Proceedings* of the Convention. Ophthalmic apparatus and surveying instruments occupy second and third place respectively. Of the five additional sections, one is devoted to experiment and research, and another to an account of the very valuable collection of historical instruments and books.

The catalogue is well produced, and should be studied by all engaged or interested in the optical industry. J. W. F.

Organic Chemistry.

A Text-Book of Organic Chemistry. By Prof. Dr. Julius Schmidt. English edition by Dr. H. Gordon Rule. Pp. xxiv + 798. (London and Edinburgh: Gurney and Jackson, 1926.) 25s. net.

We learn from the preface that this translation of Schmidt's "Kurzes Lehrbuch der organischen Chemie" arises from the encouraging results that attended the adoption of the German original as a text-book for the advanced students in the University of Edinburgh, and indeed the translator has done his work so admirably and produced so readable a book that there can be no question that it also will find a similar welcome in other English-speaking universities. It is the type of book that the teacher can recommend with confidence to the more ambitious second-year and pass students in organic chemistry, and, in so far as any single text-book can meet the ever-growing requirements of the honours students of a university, this book will prove both helpful and useful.

Following a general introduction of 68 pages, the book treats of the chemistry of the carbon compounds in 687 pages under the three sections (1) the aliphatic or fatty compounds, (2) the carbocyclic compounds, and (3) the heterocyclic compounds. It is obvious that in so limited a space the treatment of so vast a subject could not be wholly adequate, and in this respect the general introduction is perhaps the weakest part of the book; the description of the methods of qualitative and quantitative analysis, for example, is condensed into seven pages and unrelieved by any diagrams. In the three main sections, the chemistry of the hydrocarbons and their derivatives is discussed under their respective headings in the usual order, and one of the most valuable features of the book is the introduction of numerous sub-sections dealing with special groups of compounds—of natural or synthetic origin—as they fall within the category of the compounds under discussion. Some of these are of special interest, as for example those dealing with the polypeptides, with rubber, with the depsides, with the tannins, and with the vegetable alkaloids; the last forms a valuable monograph on the chemistry of these important compounds.

Judging from the numerous references to recent literature, the book has been carefully brought up-to-date, and it is surprising, therefore, to find no reference to the replacement of 'benzine' as a dry cleaning solvent by the chlorinated derivatives for acetylene; no mention of the preparation of synthetic methyl alcohol from water gas; no reference to the now extensive use of thionyl chloride in the preparation of acid chlorides; and no mention of the iodonium bases. In the preface the author states that "although the greater number of references to German literature contained in the original have been retained, some progress has been made towards the inclusion of representative English and American work"; it is therefore to be hoped that when further progress in this direction has been made, many of the unfortunate omissions from the present edition may be rectified, as for example Werner's work on the chemistry of urea, and Armstrong's and Wynne's classical researches on the chloro-derivatives of naphthalene.

Whilst the text is singularly free from errors, the following have been noted: p. 99, line 6 (from bottom), for "arsenite" read "arsinate"; p. 118, line 14, the equation should read $PhONa + (CH_3)_2SO_4 = PhOMe + NaMeSO_4$; p. 122, line 11 (from bottom), for $\beta\beta$ read $\beta\beta'$; p. 131, line 8, for "monobromoacetamide" read "acetbromamide"; p. 199, line 22, the middle formula is faulty; p. 476, line 12, for "boiling" read "melting"; p. 142, the formation of "aldehyde resin" is characteristic of acetaldehyde only. Finally, the reviewer would like to register a mild protest against the printing in formal text-books of laboratory slang terms as "to combust," even if, on its first appearance, the offender be shielded by apologetic inverted commas.

M. A. W.

Our Bookshelf.

Forest, Steppe and Tundra: Studies in Animal Environment. By Maud D. Haviland (Mrs. H. H. Brindley). Pp. viii + 218 + 8 plates. (Cambridge: At the University Press, 1926.) 12*s.* 6*d.* net.

WITHIN the last dozen years the author has seen the tundra and coniferous forests of the Yenisei, the steppes of south-east Russia, and the luxuriant tropical forests of Guiana. From her observations she has put together a picture of animal life in these widely different environments; the different parts of the book are introduced and co-ordinated by a general account of the adaptation of living things to their environment.

The purpose of the book is to show the fauna, as a whole, in relation to the floral and physical environment, and it is interesting to contrast the account of the forest of Guiana with the books of Waterston, Bates, Belt, and the other 'naturalists.' They observed and described: the modern ecologist co-ordinates a greater body of fact, and has been trained in experimental methods, which form a mental background even if experiments cannot be carried out. We suppose that the ecologist of the present day will soon give place to students who use the experimental method more and more. One important result may be expected: nearly every ecologist believes in adaptation; will the next generation of ecologists be able to furnish experimental proofs of it?

With regard to the coloration of animals, the author takes a moderate view. She thinks that belief in protective coloration is often based on a study of colour without study of habit; the sandy lark betrays itself by twittering from the top of a stone. On the other hand, she accepts mimicry as the explanation of the shapes and habits of some membracid bugs of Guiana.

We are becoming familiar with books on ecology written, or so it seems, with a blue pencil, scissors, and a paste pot, the whole cemented to a framework of new terminology. The book under review spares us from that; it is written in plain English, which seems sufficient. We are inclined to criticise the use of English names for a variety of animals from many parts of the world. Only those who pursue zoology that they may solve cross-word puzzles could give an account of the suslik, the Tatar lark, the huanaco, barbet, and bobolink. "Jumping rabbit" is a cruel misnomer for Alactaga, which is near of kin to the jerboa.

The photographs of different types of country are beautiful; there should be more of them.

PATRICK A. BUXTON.

The Theory of Electricity. By Prof. G. H. Livens. Second edition. Pp. vi + 427. (Cambridge: At the University Press, 1926.) 16*s.* net.

THE first edition of Prof. Livens' "Theory of Electricity," published in 1918, was reviewed in NATURE in 1919 (vol. 103, p. 142), and therefore the present notice need only take account of the changes introduced in the new edition. In its present form the book has been very much curtailed—from about 700 large octavo pages to rather more than 400 crown octavo pages—but the clear print characteristic of the series of the Cambridge University Press has been retained. A considerable amount of matter, relating principally to the detailed treatment of a considerable number of special problems, has been omitted in all cases where a full account is given in other books, but we are glad to note that the very careful and full discussions of fundamental principles and points of difficulty, so characteristic of the first edition of the book, have been retained in their entirety. Consequently, the work can be as highly recommended as before as an introduction to the theoretical side of electromagnetism, and in conjunction with such a detailed text-book as that of Jeans, gives as full an account of the theory in all its aspects as is to be found in any language.

In one point Prof. Livens has introduced a decided innovation on the usual treatment. He uses the term *magnetic force* for what is usually termed the *magnetic induction*, **B**, reserving the term *magnetic induction* for the vector **H**, which he regards as the derived vector. The main effect of this innovation appears in Chapter v., on the dynamics of the magnetic field, where the potential energy density of a distribution of magnetic polarisation of intensity **I** is written as $-(\mathbf{IB})$, in place of the usual $-(\mathbf{IH})$. Thus a *negative* potential energy density is obtained instead of the usual positive value; when this is interpreted as *positive* kinetic energy of hidden motions, according to the usual method of Lagrangian dynamics, a result is obtained which is certainly more consonant with theories of the ultimate origin of magnetism than the usual result of the classical theory. To us it seems that the whole question is a very debatable one, and may very well be left to the future for its ultimate decision.

Potash: a Review, Estimate and Forecast. By Dr. J. W. Turrentine. (The Wiley Agricultural Series.) Pp. ix + 188. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1926.) 15*s.* net.

FIFTEEN years ago, America's entire dependence upon imported potash led her to initiate a survey of possible home sources of this essential substance, which was scarcely completed when the breaking out of the War emphasised the importance of developing domestic resources. In pre-War days, Germany practically held the monopoly of the world's potash supply, but afterwards, when France obtained possession of the Alsatian mines, an agreement was made whereby Germany dealt with 62·5 per cent. and France with 37·5 per cent. of American and other demands for potash. In 1922 the world consumption was 1,600,000 tons of potash salts, far below the limit of producing capacity of Germany alone. At present the price is below pre-War rates, and this has caused in America an almost entire deflation of the development of the potash industries which had arisen during the War period. America's need is to push the domestic production of potash to such a point as to secure the possibility of the production of full home supplies in case of war.

Kelp is a valuable asset, as iodine and potash can be obtained as by-products from the manufacture of kelpchar, a very active decolorising carbon. Other sources of supply which can be exploited successfully are surface lakes, subterranean deposits, silicates, industrial wastes (both organic and inorganic), and cement-mill flue dust, the last being a very important potential source. Ninety per cent. of the potash entering American markets goes to agriculture, but the ten per cent. is of equal importance in that it is required for many industries. The feasibility of the recovery of sufficient potash from available home resources has been demonstrated, and the immediate problem is that of perfecting the methods employed and rendering the recovery process an economic proposition.

Mono-Alu Folklore (Bougainville Strait, Western Solomon Islands). By G. C. Wheeler. Thesis approved for the Degree of Doctor of Science (Economics) in the University of London. Pp. xv + 396. (London: George Routledge and Sons, Ltd., 1926.) 21*s.* net.

This collection of tales and song-texts given in this volume was made during a stay of ten months in Alu and Mono, Bougainville Strait, in 1908–9. The author has given the texts as taken down from the dictation of a Mono-Alu man, son of a late chief, and the Mono text is given in all but eight cases. Although traces of the old Alu speech are to be found in the tales, that language has practically disappeared and Mono has taken its place, owing to the conquest of Alu by the Mono people some sixty years ago. In these islands, therefore, Mono-Alu-Faura now form a unit area. The tales as presented by Dr. Wheeler provide much valuable material for linguistic study, but more important in some respects is the light they throw on the culture of the people. The tales, indeed, enshrine much that has already passed away. Dr. Wheeler himself points out, for example, that the incident of wrapping blood in a leaf which occurs in one of the most interesting and bizarre of the stories, in the actual practice is a feature of a rite analogous to the motive. In another story bones renew their life, a motive which stands in relation to the burning rites for a dead body in the Mono area. Similar analogies and references could be quoted time after time. Dr. Wheeler's scholarly volume will well repay careful study.

The Aspergilli. By Charles Thom and Margaret B. Church. Photomicrographs by G. L. Keenan. Pp. ix + 272 + 4 plates. (Baltimore, Md.: Williams and Wilkins Co.; London: Baillière, Tindall and Cox, 1926.) 22*s.* 6*d.* net.

While this work is primarily and confessedly taxonomic, the authors have brought together most of the scattered information on the Aspergilli, and have given a comprehensive survey of the genus from a few different points of view. Part I. deals with such different aspects as culture methods, morphology, and special physiology of these forms. A very interesting chapter is devoted to enzymatic activities, and their economic significance in the production of acids, *sake*, taka diastase, etc., while their pathogenic importance in reference to man, birds, and insects is treated in another.

Part 2 of the book is devoted to a taxonomic revision of the whole genus based on the examination of large numbers of forms from natural substrates, and the 350 strains which the authors have grown in pure cultures in their own laboratory. While the sixty-six odd accepted species of Aspergilli have been considerably multiplied, an attempt has been made by the authors to indicate real relationships in the presentation of their various groups, and the diagnostic scheme in their keys has been so arranged as to bring together closely allied forms. A fairly exhaustive bibliography is appended to the work, which forms a welcome addition to current mycological literature.

Maori Symbolism: being an Account of the Origin, Migration, and Culture of the New Zealand Maori, as recorded in certain Sacred Legends. Report made by Ettie A. Rout, from the evidence of Hohepa Te Rake (an Arawa Noble). Pp. xxxii + 322 + 32 plates. (London: Kegan Paul and Co., Ltd., 1926.) 21*s.* net.

In this book Mrs. Rout reports the sacred lore of the Maori as faithfully transmitted to her by a Maori noble, Hohepa Te Rake, and solemn declarations to that effect by both participants in the production form part of the contents. It is, however, difficult to accept these statements at their face value, as the lore is not given in its original form, but as interpreted in the light of a theory of the origin and migrations of the Maori, based upon identifications which trace them back to Assyria and suggest identity of culture in Egypt, America, and elsewhere. The illustrations, which are exceptionally well reproduced and in another context would be both interesting and suggestive, have been carefully selected with this end in view. In spite of this defect the book does, however, contain a very full account of the customs and practices of the Maori which conduced to sound sanitation, personal cleanliness, and good health.

Practical Colloid Chemistry. By Prof. Wolfgang Ostwald, with the Collaboration of Dr. P. Wolski and Dr. A. Kuhn. Translated by Dr. I. Newton Kugelmass and Dr. Theodore K. Cleveland. Pp. xvi + 191. (London: Methuen and Co., Ltd., 1926.) 7*s.* 6*d.* net.

This laboratory manual has been well known to workers in colloid chemistry since the first German edition appeared in 1920, and in the variety and completeness of the course provided it reflects the versatility and enthusiasm of the chief author. He has, however, been badly served by his translators, whose frequent misrepresentations need to be seen to be believed, and to be compared with the German to be understood. P. C. L. T.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Band Spectrum of Mercury from the Excited Vapour.

I WISH to bring forward one or two additional results on this subject in supplement to my letter published in NATURE of Nov. 27, 1926.

In the first place, I found that the green visual band, extinguished by heat, recovers to some extent as the excited vapour moves on to a cold part of the tube. This effect has been satisfactorily photographed.

As emphasised in published papers, the main part of the band spectrum covers the whole region on the less refrangible side of the resonance line λ2537, at which point it abruptly begins.

I now find that the 'forbidden' line λ2270 is present on the plate, and that a separate stretch of band spectrum reaches from this point to the band λ2345. In the region of wave-length less than λ2270, and also in the region between λ2345 and λ2537, the background of the spectrum is quite dark.

Prof. Takamine has suspected that the band λ2345 was associated in some way with the 'forbidden' line, and he suggested to me some time ago to look for this line in the excited vapour. It was not to be seen on the negative then available. My present negative has been made with an improved technique, and exposed for as much as 100 hours. I do not think it has been suspected before that a stretch of continuous spectrum begins at λ2270, and connects up with λ2345 and the associated bands of intermediate wave-length.

RAYLEIGH.

Chelmsford, Essex, Mar. 1.

Some Comments on Current Science.

THE COURSE OF COSMIC EVOLUTION.

MANY, like myself, will be interested in Dr. Jeans's letter in NATURE of Feb. 26, p. 315, and will wish to congratulate him on the confirmation, or rather the realisation, of his calculated states. The question will be asked, however, whether he is led to think that the universe ever was in that uniformly distributed initial state, or whether its proved instability is an argument that that condition never actually occurred. One view of evolution is that the general appearance of things on the whole was not very different from what it is now, and that the various processes have gone on concurrently in different regions. I am wondering, and I expect others will be, whether it is his view that the universe evolved, so to speak, as a whole, with an initial state entirely different from its present state. In a gas of density 10^{-31} I reckon the molecules about 5 metres apart on the average—a curious state of things, of philosophical importance, if it ever really happened. There can scarcely have been a beginning for time! Though I suppose that, as there is a beginning for a solar system, there may have been a beginning for the universe as a 100-inch telescope sees it. But it is not an easy idea: or rather perhaps it is too easy to be satisfying; unless the universe is really infinite, when even the scope of the 100-inch would be but a unit.

THE DOWSING OR DIVINING ROD.

I have not myself studied the particular activity of the subconscious mind that is apparently operative in the detection of things hidden from the normal senses, but I have discussed it from time to time with the late Sir William Barrett, and I feel justified in saying that he would have appreciated and welcomed the review by Dr. H. R. Mill in NATURE of Feb. 26, p. 310. That we have as yet no satisfactory explanation of the phenomenon is true enough; but then that is equally true of many other obscure human and animal faculties, which react to the environment in a surprising manner. My own view is that we shall not begin to understand these things so long as we attend to our material environment alone. There is an etherial environment too; and it may be that that is the home of the subconscious, in the same sense as matter is the home of the conscious part of our minds. Probably everything psychic has a physical concomitant, which can some day be tracked down; but the adjective 'physical' is not limited to matter, else light and electric waves would be excluded. Already our instruments respond to non-material though truly physical disturbances; and it may be that some unrecognised parts of our bodily mechanism, or unconscious brain centres, are capable of response too.

I am myself inclined to think that we shall find ourselves more directly or immediately concerned or connected with the ether than we are with matter, in spite of the fact that matter looms so large to our familiar senses. We can only gradually confirm or negative a guess of that kind by following such clues as are available. I heartily re-echo the concluding words of the review, to the effect that those who only attend to the subject with a determination to prove that the whole thing is humbug will discover nothing.

PATHOLOGY OF LAMP FILAMENTS.

It sometimes happens that the facts of one science can be suggestive of ideas and possible fruitful inquiry in another quite different science, provided the devotees of that other science are made acquainted with the relevant or suggestive facts; but admittedly the disciples of the first branch of knowledge must be cautious how they obtrude, lest they seem presumptuous and interfering in matters beyond their ken. In the heading of this letter I venture to use the non-physical term 'pathology' in order to direct the attention of real pathologists to a recently observed and explained trouble encountered by manufacturers of electric lamps and vacuum valves, the filaments of which are sometimes subject to what may be called an inorganic, non-microbic, and purely chemico-physical disease.

At a recent meeting of the Royal Society of Arts on Feb. 16, an interesting paper, accompanied by experimental demonstrations, was read by Mr. C. C. Paterson, director of the Research Laboratories of the General Electric Company at Wembley: and from this paper I want to make a few extracts in order to attract wider attention to some of the results obtained by the brilliant staff at work there under exceptionally favourable conditions. The thorough knowledge necessary before trustworthy pieces of apparatus can be manufactured and turned out by the million is obvious, and the experience gained in the organisation of such mass-production is often of scientific importance. Here, then, is one of the side-issues of lamp and valve manufacture.

It is found that in gas-filled lamps, the filaments of which are made of tungsten, it is essential to reduce the residue of water vapour down to the lowest minimum possible; for water vapour has, on the coiled filaments of such lamps, a specific and recognised action that gradually and sometimes rapidly weakens and destroys the ignited filament, by thinning it down at one place and thickening it in another; the action, once begun, tending to go on more and more rapidly, since the thinner part gets automatically more heated and the thicker part more cooled. The action is described by Mr. Paterson as follows:

"Molecules of water vapour left in the bulb are decomposed into hydrogen and oxygen in contact with the hot parts of the filament. The oxygen immediately combines with some of the tungsten atoms at the hottest spots with the formation of tungsten oxide. This tungsten oxide is deposited on to a neighbouring cooler part of the filament where reduction of oxide can take place, [since] the cast-off hydrogen atoms can again claim their oxygen from the tungsten oxide. The tungsten atoms thus left coalesce with the filament at its cool point, with consequent thickening of the filament. Meanwhile the molecule of water vapour, now re-formed, is free to attack again the hotter part of the filament. This point becomes continuously hotter by virtue of its diminishing diameter. Thus the molecules of water vapour act much as ants, carrying particles of tungsten from one place and building them up in another, and become available over and over again as the carriers of tungsten atoms. Hence the potency of water vapour as a destructive agent. The quantity must be reduced to vanishing proportions if it is not to cause wastage and growth in this way during the long high-temperature life of a gas-filled lamp."

That water should act as a catalytic poison, in this way, is rather in accordance with the pronouncements of Prof. H. E. Armstrong about the influence of water and of traces of impurity in chemical reactions generally; for under other conditions traces of other substances may be acting in a similarly unstable or top-heavy way. In fact, Mr. Paterson elsewhere says that "in gas-filled lamps, and before gas-filling takes place, every possible trace must be removed of water vapour, because this acts in relation to the gas-filled lamp filament as cancer does in the animal body, and causes alternate local growths and wastage." He further points out that at the high temperature of a lamp "chemical reactions are extraordinarily vigorous, and many of them unexpected—water vapour is not the only vapour or gas which must be guarded against."

Whether there is likely to be any impurity in the blood or tissues that under vital conditions might act in a catalytic manner and build up local growths at the expense of tissue elsewhere, even in the absence of any microbe or customary disease agent, it is for biologists to decide. The idea may have occurred to them; but an actual instance occurring in the physical laboratory may cause them to pursue the idea further. I will only say this: The activity of an electrolyte capable of dissociation in a liquid—as in many saline solutions—is known not to be very different from the activity of the free molecules of a gas.

OLIVER LODGE.

Lake, Salisbury.

Hereditary Choice of Food-plants in the Lepidoptera and its Evolutionary Significance.

THE problem of the practical differentiation of species in Nature stands so much in need of experimental work, that the recently published paper by Dr. J. W. Heslop Harrison on an apparently successful attempt to influence the hereditary instincts of a sawfly (*Proc. Roy. Soc.*, Series B, vol. 101, pp. 115-126) will be read with interest, and I am induced to offer one or two critical remarks.

This sawfly, *Pontania salicis*, is stated to feed on many species of Salix, but in any given locality to restrict itself habitually to some one (not the same) species, although several others may be equally plentiful. I do not dispute the statement, but in the whole of the Lepidoptera I have never heard of a similar instance. Salix, in particular, supports a large number of Lepidoptera, but in general the only discrimination made is between the rough- and smooth-leaved species (probably influenced by touch rather than taste), and, again the choice of *S. repens* by certain species seems due rather to the superior shelter afforded by the dwarf habit. Also the Pontania is a gall-maker; and the case of gall-producers, where complicated reactions ensue between insect and plant, may be specially difficult to understand. In the experiments the change was produced immediately, and was completely established in three years; there must be some quite unusual element here.

From this single and quite exceptional case, however, Dr. Harrison proceeds to deduce what he calls a new principle of evolution, which I understand to be that in phytophagous insects (for example) pairs of allied species are produced by the accidental transference of larvæ from the usual food-plant to an adjacent allied plant, or even to one usually associated with it but not allied. Several pairs of species of Lepidoptera are instanced as suitably associated "in Britain," as, for example, *Cerura bicuspis* and *C. furcula*, but this argument is wholly fallacious, involving the assumption that one of the species originated here; both range over the whole of northern and central Europe and Asia, and the circumstances of their origin are entirely problematical. But is there anything new in the principle? All lepidopterists are aware that not merely pairs, but also whole groups of species, tend strongly to feed on allied and associated plants, and this would appear to be probable on any theory of the mechanism of evolution; and microlepidopterists in particular have long ago suggested that the closely similar species in such genera as Phthorimæa and Lithocolletis, each attached to its own food-plant, originated as phytophagic races.

The trouble is that no one has yet evolved a new species by this means; and I shall be very much surprised if, when this is accomplished, it proves to require only three generations of the insect. But even this achievement will not go very far to explain the formation of species in the Lepidoptera. A very large proportion of these (such as most of the very common British Caradrinidæ) have larvæ which feed either on grasses generally or on miscellaneous low plants almost indiscriminately, and without any variation resulting except perhaps of size; and a further large class feed on dead wood and dry vegetable refuse. The same influences which have resulted in the multiplication of species in these groups must be supposed equally efficient in the groups which are more specialised in their tastes; and, subtracting their effect, not much will remain for that of the food-plant. I have even recorded ("Exotic Microlepidoptera," vol. 2, p. 521) the case of two Indian species of Bactra, separable with difficulty, known only from series reared together from larvæ feeding on the same individual plants in the same way at the same time.

Rotation of Bodies with Dielectric Surfaces in Electrostatic Fields.

Referring to Dr. S. W. Richardson's letter in Nature of Feb. 12 on the rotation of dielectric bodies in electrostatic fields shown by Mr. L. G. Vedy and Mr. G. Gowlland, at the recent exhibition of the Physical Society, it may be of interest to point out that at the Exhibition in 1896 I showed two experiments which seem to bear on the subject. The first was with a *highly dried* dielectric liquid. If a spherical electrode is fixed some 5 mm. or 6 mm. above the surface and charged from one pole of a Wimshurst, the other pole being earthed, the liquid quietly rises up in a conical form, attaches itself to the electrode, and remains suspended while the field is maintained.

If this same liquid is then exposed to the atmosphere or otherwise absorbs a small percentage of moisture, on repeating the experiment—while there is still a tendency to lift the liquid—there is an even stronger one to depress it in places resulting in great turbulence, hollows, and sometimes whirling motions, all of which vanish if the liquid is again dried.

In a letter in Nature for April 5, 1924, I showed that the properties called 'absorption' in dielectrics at ordinary frequencies are also due to small percentages of moisture and can be greatly altered by varying this. It would, therefore, appear that with dielectric liquids these effects are also due to 'absorption'.

If a short bar of a good dielectric, but showing some absorption, is placed between two electrodes, but with air-gaps, and a fairly strong field is maintained in a dried atmosphere for some time and it is then, with insulating tongs, brought near an electroscope, the two ends show opposite charges, and these take time to die out. This action is separate from the opposite induced polarity of the mass of the molecules of the dielectric, which is instantaneous, and disappears instantaneously when the field is removed. This latter action appears to take no part in the rotations which are due to interaction between the field and moisture in the dielectric, or to its 'absorption'.

In the letter referred to I mentioned that to produce the absorptive effects it was not enough to assume the dielectric constant of water as 80, but that the only conclusion was that when small percentages of moisture are occluded in dielectrics, much, at any rate, must exist in an ionised form, when the reaction of the separated ions with an outside field would be much more powerful.

From observation of the experiments I gathered that rotation only occurs when brush discharges of sufficient magnitude pass between the electrodes and the rotating body.

If a sheet of a good dielectric is held near such a charged electrode, and is then brought to an electroscope, the surface of the dielectric shows a charge, but it is *of the same polarity* as the electrode producing it, instead of having the opposite induced polarity which it would have had if the dielectric had been held at a greater distance.

Now when a dielectric having in it ionised moisture is placed in an electrical field, the negative ions are strongly attracted towards the positive electrode, and vice versa, and these ions tend to be drawn through the dielectric and to accumulate under the opposite surfaces. Primarily this would produce opposite induced polarity; but if the field is sufficiently strong there is evidence that some of the opposite ions are actually pulled out of the dielectric and drawn to the electrode. This leaves the dielectric opposite the electrode with a free charge, *but of the same sign* as the electrode, causing strong repulsion.

To start the rotations there must be initial movement of the dielectric or some want of symmetry. The rotation takes place either clockwise, or counterclockwise, depending on the direction of the initial impulse.

Thus if a block of dielectric is placed in a strong field the electrodes extract opposite ions from the two opposed surfaces and leave each with a strong charge of the same sign as the opposite electrode. When the dielectric is given a slight movement one way or the other, these charges are repelled by the electrodes and both unite in turning the dielectric in the same direction. Now these charges in the dielectric, if the dielectric is what is called 'good,' or has a sufficiently high resistance, take some time to die away. They are continually renewed as fresh surfaces of the dielectric pass the electrodes, and, on the other hand, as the rotation carries each charge round towards the next electrode the charge will be of opposite sign and therefore will be attracted until it gets under the electrode. As it comes under the second electrode the attraction will draw the ions of opposite polarity out of the dielectric and again leave it with a charge of the same sign, again producing repulsion, all the actions thus uniting to produce motion in the same direction.

Surface moisture will also give rise to the same actions if the film is sufficiently thin. If, however, the film forms a layer of low enough resistance, surface conduction will neutralise the opposite charges on the dielectric and thus reduce or stop the rotation. This was observable in some of the experiments. For example, a metal cylinder wrapped with paper would not rotate until the paper was dried, and the same inability to rotate occurred with a glass beaker before it was surface dried.

Speaking generally, this seems to be the explanation of these interesting demonstrations.

I have been investigating actions of this character during the last two years under conditions calculated to show their causes more clearly; the results, it is hoped, will be published shortly.

The Effect of Intense Light on the Energy Levels of Atoms.

In 1923, Bohr (*Z. f. Phys.*, 13, p. 117; 1923) directed attention to the fact that the usual formulæ of the older quantum theory might not be strictly applicable to atoms which are subjected to intense radiation fields of high frequency, such as those of ordinary light. Schrödinger (see particularly equation 16, *Ann. d. Phys.*, 81, p. 109; 1926) has formulated the differential equation for the ψ-function of an atom exposed to a harmonic electric force, and from this the allowed values of the quantity E appearing in the equation may be determined. In such a case, however, the physical interpretation of E is doubtful, though it seems highly probable that it represents the (average) energy of the disturbed atom. Thus we cannot be certain that the equation $E_1E_2 = h\nu$ is correct for calculating the frequencies emitted by such an atom. Whatever be the final formulation of the theory, it seems reasonable to suppose that the energy levels of atoms in sources at very high temperatures may be modified by the electric and magnetic fields of the radiation from the source itself.

Mr. W. Kuhn (*Z. f. Phys.*, 38, p. 440; 1926) devised an interesting experiment for detecting changes in the energy levels of sodium atoms illuminated with wave-lengths near the D lines, and performed it in collaboration with Mr. R. de L. Kronig. By analogy with the classical theory of dispersion, such wave-lengths should be capable of producing disturbances quite large compared with those produced by wave-lengths much farther from the resonance lines. Briefly, the experiment consisted in studying the D line absorption of sodium vapour illuminated by a suitable continuous background, (1) when it was also illuminated by the broadly reversed D lines from a very intense sodium source, and (2) without this intense illumination. The temperature of the absorption vessel was so regulated that wave-lengths extending about 0·03 Å.U. on either side of the centre of a D line were absorbed and the temperature of the intense source was such that the reversal was about 0·06 Å.U. wide. The effective radiations lay mainly at a distance between 0·03 and 0·06 Å.U. from the centres of the D lines, so that the total range of wave-lengths utilised in the neighbourhood of either D line was about 0·06 Å.U. Kuhn states that an approximate computation indicates the possibility of a shift of 0·15 Å.U. for the D lines in absorption, due to the alteration of the energy levels of the sodium atom. He gives no details of his calculations. Therefore no statement can be made here as to the way in which the phase differences of the monochromatic constituents of the incident light were taken into account. But leaving aside all theoretical questions, the experimental result was that no such broadening or shift could be detected.

It is the purpose of this note to point out that if such an effect exists, it should be readily possible to detect it in the solar spectrum, or better, in the spectra of very hot stars. To show this we note that the intensity of the yellow sodium light used by Kuhn corresponds to an energy density in the light beam of $400 \times 900/c$ ergs per c.c. For an atom at the surface of the sun we may suppose as a rough approximation that the effective energy density corresponds to about five-sixths of the energy density of isotropic black body radiation. That is, if we consider a unit cube in which the atom is placed, we see that black body radiation of the temperature appropriate to the sun streams in through five sides of this cube, since about one-half of the total solid angle is subtended by the sun at this position. Calculating from Planck's formula, the energy density of black body radiation carried in a wave-length interval of 0·06 Å.U. units at the position of the D lines, we find the value $3{\cdot}4 \times 10^4/c$ ergs per c.c. This must be doubled to take account of radiations in the neighbourhood of both D lines. The result, $6{\cdot}8 \times 10^4/c$ ergs per c.c., is twenty times as large as the figure given by Kuhn.

Kuhn's calculation of the change in energy levels depended upon the assumption that the atoms are subjected to an electric force E obtained from the equation

$$\text{Energy density} = E^2/4\pi.$$

This is open to considerable question. In calculating the actual electric force acting upon an atom, it may be necessary to take the microscopic structure of the wave front into account. Looking at the question from the point of view of the theory of uni-directional quanta (simply for the sake of convenience), it seems reasonable to suppose that many of the absorbing atoms may not be affected at the moment of absorption by any quantum belonging to the intense beam. This objection may also be applied to speculations on the possibility that atoms are oriented by the electric and magnetic fields of incident radiation, an idea which is sometimes invoked to explain the polarisation of resonance radiation in cases which do not yield to the usual theories. Arguments based on analogy with Huyghens' principle in classical optics could no doubt be given to show that the detailed structure of the wave fronts may be neglected; but the attitude adopted here consists essentially in questioning the validity of such evidence.

Further, it should be remembered that in Kuhn's experiment (uni-directional illumination) only half the energy density is effective in producing a polarisation of the atoms parallel to a given direction in a plane normal to the beam. A similar factor must be applied for atoms in celestial sources, but since we are interested only in the order of magnitude of the effects, we shall not discuss the matter further.

It may be that an effect of this kind exerts a detectable influence on wave-lengths in celestial sources. Whatever the verdict may be, the question can only be settled by those familiar with the complexities of astrophysical spectroscopy. Such an effect cannot be easily disentangled from those due to other physical disturbances. The question should certainly be considered in future discussions of the Einstein red shift and of peculiar motions in the line of sight.

The Behaviour of Polyploids.

Mr. Huskins' description (Nature, Jan. 8, p. 49) of the strict correlation he has observed between abnormal chromosome behaviour and abnormal breeding results in fatuoid oats encourages me to put forward suggestions based partly on analogous observations of my own.

The basic chromosome number throughout the genus Prunus appears to be 8. *P. cerasus*, *P. acida*, and *P. fruticosa* are tetraploid relatives of the diploid *P. avium*; *P. domestica* and *P. insititia* hexaploid relatives of the tetraploid *P. spinosa* and the diploid *P. cerasifera* and *P. triflora*. In both the sour cherries and the plums I have found in particular individuals at one reduction division complete pairing, at another the formation of a trivalent and a univalent instead of two of the pairs, or of two trivalents and two univalents instead of four pairs. This occurrence in an orthoploid is analogous with what Mr. Huskins has observed. Furthermore, in these cherries secondary association of bivalents may occur, and in some cases the chromosomes are associated in eight groups of four. The segregation of the parts of these quadrivalents must be, from their form, if not haphazard, at least not predetermined.

There is, however, a further significance in this variable pairing which is perhaps better shown by another example. In 1914 Mr. Crane, at Merton, crossed *P. cerasifera* on *P. domestica*; the single seedling resulting from 750 indoor pollinations has now been examined. Behaviour at the reduction division is not distinguishable from that in tetraploids such as the sour cherries, and irregularity is of the same degree. We have thus shown, what has not yet been proved in the hexaploid cereals, that the three sets of the gametophyte complement of the plum are all homologous with one another, or with the one set of a related diploid species.

If, on hybridisation, chromosomes of any one set in the plum are capable of pairing with their respective homologues of any of the other five sets, we must not assume that this freedom is effective within the species itself, yet it is possible that choice of mate is less restricted than in a simple diploid. The importance of this is indicated by a calculation of the number of chromosome-types in the offspring that may be produced by selfing a diploid with 48 chromosomes, in which every one of the chromosomes is distinct from its homologue, and a similar individual in which complete freedom of pairing prevails—a functional hexaploid. In the first case the number is $1{\cdot}4 \times 10^{14}$ and in the second $3{\cdot}6 \times 10^{\text{[illegible]}}$; this disproportionate increase no more than corresponds with the unparalleled diversity which Crane (1921) has actually discovered in the selfed offspring of certain plums.

This analysis of a polyploid brings us, I think, to the same conclusion as the synthetic method that has been successful in Nicotiana, *Primula kewensis*, and the Brassica-Raphanus cross and accidentally, as it were, in *Primula sinensis* and Fuchsia—the conclusion that polyploids have often arisen as the immediate or eventual result of hybridisation between diploid species and that, although the varying affinities between their parents are reproduced in the varying affinities between their constituent chromosome sets, their constitution is hybrid in all those respects in which their diploid parents differed. It is noteworthy in this respect to recall that the most successful experiments in the study of hybrid vigour have been carried out with diploids.

Now so long as a polyploid pure line is selfed its intrinsic hybridism remains latent, but on crossing with a related species possibilities of *secondary segregation* must be considered. Supposing, for example, speaking crudely for the sake of brevity, we imagine the tetraploid species *Triticum durum* made up of two species A and B and *T. polonicum* of two others C and D, how will pairing take place in an F_1 between these two? It has been assumed always that pairing is only possible between A and B chromosomes on one hand and those of C and D on the other. My observations and the whole probability with regard to the relations of the original species incline me to conjecture that, while this may be true of most of the members of each set, others are likely to be less fixed in their association, and others again possibly pair A with B and C with D. Characters in which the parents differed, determined in these last chromosomes, would then never be fully recovered from the progeny of the cross. Further, new characters would be discovered sometimes even exaggerating the peculiarities of one parent, and expected new combinations would fail to occur. These phenomena are exactly what Backhouse (1917) observed, ascribing them to "zygotic inhibition," and Engledow (1920) ascribing them to "shift"; although it has always been clear that these were not the inevitable concomitants of interspecific hybridisation (Belling, 1915). Gates (1915) has described a similar occurrence in forms not polyploid but possibly aneuploid, ascribing it tentatively to "gametic contamination," but offering the still adequate alternative of a cytoplasmic influence.

I venture to conclude, therefore:

1. That the possibilities of segregation in a functional polyploid are enormously enhanced as compared with those in a comparable diploid.
2. That a pure line of a polyploid species may retain the heterosis of an interspecific F_1 when selfed.
3. That crossing such a line with a related species exposes the latent heterosis, causing
    (*a*) Appearance of new and extreme forms (Backhouse);
    (*b*) Failure to recover the parental form (Engledow and Vavilov).

Prothetely in Insects.

IN the hemimetabolic insects, the nymphs at a very early stage of development possess rudiments of almost all the organs of the adult, for example, wings, compound eyes, etc., whereas in the holometabolic forms the appearance of these organs is postponed to a definite later stage, namely, the pupal instar. Numerous cases, however, are on record in which the larvæ of the holometabolic insects also showed wing pads, etc. The first communication on this subject was made so long ago as 1813 by Majoli, who observed that certain silkworms after the fourth moult developed directly into moths without spinning a cocoon or passing through a pupal stage. It was in 1896, however, that Heymons definitely described the phenomenon in mealworms (*Tenebrio molitor*). Kolbe in 1903 reviewed all the cases known at that date, and concluded that the appearance of these organs is premature and is due to accelerated development; he therefore gave the name 'prothetelie,' or prothetely, to the phenomenon. Since 1903 numerous cases of prothetely have been reported, and thus the phenomenon is now recognised to be of fairly common occurrence amongst insects, especially in the orders Coleoptera and Lepidoptera.

In view of the important bearing of prothetely on the metamorphosis, phylogeny and evolution of the higher orders of insects, numerous theories have been propounded, all based on the assumption of Kolbe that the phenomenon was a case of accelerated development. Unfortunately, nobody tried to verify the assumption by experiment or otherwise.

In 1924, while breeding *Tenebrio molitor*, the species which had afforded the classic example of prothetely, I observed in a culture which was being kept at about 28° C. that although most of the larvæ pupated normally, some remained, which, as time progressed, grew more and more inert, ceased active feeding, and began to show wing-pads and other characters usually associated with prothetely. The larvæ thus affected, if they moulted at all, did so with great difficulty. Only a few of them ultimately pupated, but the pupæ were abnormal in appearance. The affected larvæ, when put in a lower temperature, became active and lively.

These observations suggested that the prothetelic changes in mealworms were not obviously the result of the accelerated development on account of which the phenomenon is designated prothetely, but rather of inhibited metamorphosis.

This hypothesis was investigated by means of a long series of experiments, which conclusively showed that wing pads and several other imaginal organs, including the proliferation of testes, appeared in those larvæ only which were kept at a temperature too high or too low, and consequently could not pupate, although controls of the same brood kept at optimum temperature had in the meantime pupated. Thus under the influence of unsuitable temperature the metamorphosis of the individuals had been inhibited and, in spite of this, there had been a tendency for their imaginal organs to appear at the proper time.

These experiments were reported in the *Jour. Camb. Phil. Soc.*, 1924, when it was also shown that in almost all the previously recorded cases where details were known, the pupal organs had most probably appeared only in those individuals whose larval life had been excessively prolonged. In view of this the writer suggested that all the cases of prothetely were really 'neoteny,' and that the name 'prothetely' for the phenomenon was not only superfluous but also misleading.

These conclusions, diametrically opposed to those hitherto held, naturally required confirmation. This has come from quite an independent source. Recently (*Jour. Exp. Zool.*, 1926) Chapman, apparently unaware of my work (he does not make any reference to it), has studied the phenomenon in *Tribolium confusum* Duval, and has also come to the conclusion that wing-pads, etc., appear in those larvæ alone whose metamorphosis has been inhibited. It is interesting to point out that in his experiments the inhibiting factor was not unsuitable temperature, but a peculiar gas given out by the beetles.

There is therefore no doubt that the name 'prothetely' for this phenomenon should be dropped, and along with it should go the numerous theories based on the assumption that the phenomenon is a case of accelerated development.

Incidentally, the above facts raise several questions as to the origin and mode of metamorphosis. A discussion of those must be reserved for a future communication.

The Occurrence of Branched Lint Hairs in Egyptian Cotton.

During the past three months I have been engaged on measurements of ribbon width of cotton hairs for the determination of 'fineness' as described by Harland (*Journal of the Textile Institute*, vol. 15, No. 1; 1924). In one sample of Sakellaridis of good quality a branched hair was noticed and photographed. Fig. 1 shows the hair as originally observed in a small bunch of some thousand hairs. In this instance the camera was focussed on to the lumen of the hair and distinctly shows the fibrillar structure on the inner surface of the secondary thickening as described by Balls (*Proc. Roy. Soc.*, B, vol. 93; 1922).

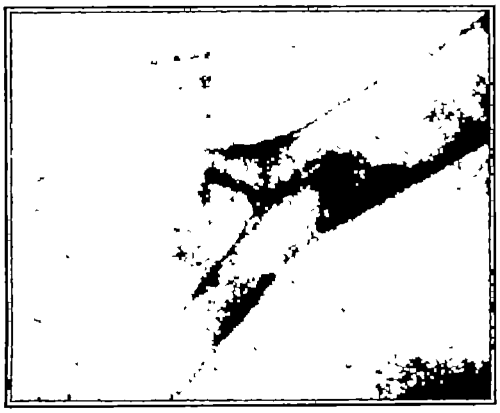

Fig. 1. (×700.)

The small lateral branch was difficult to focus owing to its being crossed by other hairs which show as dark shadows in the photograph. An attempt was then made to disentangle this branched hair and remount it so as to obtain a better view of the lateral branch. This trying operation was successfully accomplished, but not without mutilation, and a photograph taken (Fig. 2).

Further examination of this sample of cotton has revealed the existence of what might be more correctly described as lateral protuberances rather than branches. One of these is shown in Fig. 3. Investigations are being continued to ascertain the extent of the occurrence of this structure and its probable influence on the spinning properties of the cotton.

The Formation of Twin Metallic Crystals.

The reply of Messrs. Carpenter and Tamura appended to my remarks (Nature, 119, 120-121, Jan. 22) on their description of twin boundaries in metal crystals makes it clear how what I must continue to view as their misconception of the problem has arisen.

They fix attention upon an arbitrary unit of structure—in the case most discussed, a face-centred cube—and do not consider as a permissible twinning plane any plane which does not pass through the centre of this unit. This amounts to ascribing *physical significance* to the position in space of a set of lines and planes which are merely *mathematical conveniences*.

A better way of proceeding is to consider the whole array of atom-centres on one side of a twinning plane as derivable from the corresponding array on the other side by reflection therein, or by rotation about a suitable line. If, however, a unit of structure bisected by the twinning plane is desired, it can easily be found. In the case of the face-centred cubic arrangement such a unit of structure is—if my description is the correct one—a cube with atom-centres at $(0, 0, a/2)$, $(0, a/2, 0)$, $(a/2, 0, 0)$, $(a/2, a/2, a/2)$ and at points derived from the first three of these by translations of amount a parallel to the cubic axes. Atom-centres therefore lie at the centre of this cube and at the mid-points of its twelve edges.

Contrary to the most recent statement of Messrs. Carpenter and Tamura, reflection in an octahedral—[111]—plane through atom-centres involves in the diamond structure the same abnormally small distance between atom-centres—two-thirds the normal distance—as does reflection in the octahedral plane they first considered.

In this connexion it is interesting to observe that in the diamond-like structure of silicon it is possible to choose a position for an octahedral twinning plane which involves no change in least inter-atomic distance. Such planes cut orthogonally the cube-diagonal *in the usually chosen unit of structure* at points distant $a\sqrt{3}/8$, $11a\sqrt{3}/24$, $19a\sqrt{3}/24$ from a corner of the cube. One cube which is bisected by such a twinning plane has atom-centres at the points

$$\begin{cases} (a/8,\ a/8,\ a/8), & (a/8,\ 5a/8,\ 5a/8), & (3a/8,\ 3a/8,\ 7a/8), \\ (3a/8,\ 7a/8,\ 3a/8), & (5a/8,\ a/8,\ 5a/8), & (5a/8,\ 5a/8,\ a/8), \\ (7a/8,\ 3a/8,\ 3a/8), & (7a/8,\ 7a/8,\ 7a/8). & \end{cases}$$

In this case the twinning plane passes through no atom-centres.

No general rule can be stated as to whether the twinning plane for least lattice distortion contains atom-centres or not, since, as seen above, this depends upon the lattice.

The Origin of Humic Matter.

THE origin of the humic matter of coal, peat, and the soil has been the subject of controversy for many years. At present an increasing amount of support is being given to the hypothesis of Fischer and Schrader, who regard lignins as the parent substances of humic matter. The older view, according to which carbohydrates (notably cellulose) are primarily concerned in the production of humic matter, finds less support than formerly. Waksman has suggested that the humic matter of soils is a mixture of unchanged lignins with the organic substances derived from the life processes of micro-organisms.

For some time past this question has been under investigation in the chemical department of this Station. On the whole, the results so far obtained are in favour of the origin of humic matter from lignins. There is a marked resemblance between the general properties of lignins and humic acids. We are now studying the action of aqueous sulphur dioxide under pressure on a variety of humic acids prepared from natural sources and artificially. We have found that this treatment effects a true fractionation of humic and hymatomelanic acids of natural origin, and that the substances brought into solution show close analogies with the lignosulphonic acids obtained in the bisulphite treatment of wood pulp. Salts of organic bases with the 'sulphonic acids' from one variety of humic acid have been made, and found to show distinct double refraction, indicating a tendency towards crystallisation. The proportion of insoluble residue from sulphur dioxide treatment varies markedly with different preparations of humic acid, and its nitrogen content is not appreciably different from that of the original material.

These results suggest strongly that there is a close relationship between natural humic acids and lignins. It is, however, not yet possible to say whether this is due merely to the presence of unchanged lignins in natural humic acid preparations, or whether humic acids themselves are actually chemically related to lignins. Further work is in progress with the aim of deciding this question, together with the closely related question of the state of the nitrogen in natural humic acids.

Intensity Distribution in the Fine Structure of the Balmer Lines.

IN the course of an investigation of the fine structure of the Balmer lines, at present being undertaken in this Laboratory, certain preliminary results of an apparently novel character have been obtained which seem to be of considerable interest. These refer to the dependence of the relative intensities of the two components λ' and λ'' of $H_\alpha[\lambda' < \lambda'']$, referred to in a recent letter in NATURE (Jan. 29, p. 163), upon the conditions of the discharge and in particular upon the diameter of the tube in which the discharge takes place.

Three discharge tubes were used. In the first the average diameter of the capillary was 0·16 cm. The intensity ratio of λ'' to λ', about 3 : 1 in this tube, was not appreciably dependent on either pressure or current density. The average diameter of the second tube was 0·6 cm. In this case the intensity ratio, now approximately unity, was, in agreement with Hansen's results (*Ann. d. Phys.*, 78, p. 558; 1925–26), primarily dependent upon the gas pressure and to a less degree upon the current density.

In an attempt to elucidate the striking difference between the results obtained in the above cases, an apparatus consisting of a tube of average diameter 0·6 cm. fixed axially with a second of about 0·9 cm. diameter was constructed. The apparatus was arranged so that independent discharges could be sent through the axial tube and through the space between it and the outer one (about 1 mm.), the pressure being the same in both. In the former, the intensity ratio was again dependent upon the gas pressure and current density, as it was in the second tube; in the latter, the intensity ratio was practically constant, and of the same magnitude as it was in the first tube.

Electro-deposition of Rubber.

IN the description of the process of electro-deposition of rubber given in NATURE of Jan. 22, pp. 129 and 130, there occurs one statement which might be misleading to those not actually acquainted with the process. After reference to certain operating conditions it is said, "Against these advantages must be set the fact that, since rubber is a non-conductor, it is possible to obtain only comparatively thin sheets of rubber product, though further investigation will doubtless remove this limitation."

Although, of course, rubber is a non-conductor, the deposit of latex rubber particles, with or without other filling material, forms a spongy gel which is still permeated by the intermicellar liquid, which, of course, is an electrolytic conductor. Consequently the electro-deposited rubber is not actually an insulator, but is perfectly analogous to a porous diaphragm electrolytically connected with a metallic anode. Such limitations as exist in regard to the thickness of coating depend mainly on other conditions, therefore, than the formation of an insulating layer.

The Survey of the Stars.[1]

By J. H. Jeans, Sec. R.S.

At the dawn of civilisation, when man awoke from his long intellectual slumber, nine muses were appointed to preside over his various activities. Only one muse was allotted to science, and that one was allotted to astronomy. Perhaps the high gods of Olympus who arrange these things had heard of no science beyond astronomy, or perhaps they thought it the only one worth encouragement; we do not know. But it is said that since then the claims of other sciences have been admitted, and a vast crowd of junior muses have been appointed to look after them. When they all meet in conclave, many of the latter report quite extraordinary rates of progress in their particular sciences, and it has sometimes been thought that astronomy, which started first in the race, has at times shown some tendency to lag behind.

To this Urania has always had a ready answer. She can point first to the immensity of her task; sciences such as geography, geodesy, and geology, whose field of action is limited to the surface of one tiny planet, can no doubt claim to be well on towards the completion of their tasks, but the exploration of an entire universe offers a task of a different order of magnitude. She can point also to the extraordinary difficulty of this task; after once the first obvious steps have been taken, the astronomer can get nothing of value except with instruments of almost incredible precision. Moreover, instead of being able to investigate phenomena when he pleases, he has to wait on Nature, and Nature moves very slowly in comparison with human life—the whole age of astronomy, as a science, bears the same relation to the ages of the stars that it studies, as does the last tick of the clock in the dying century to the century itself. Finally, she has often been heard to remark, with a mixture of pride and sorrow in her voice, that her science presents problems of such enthralling interest that only too few astronomers can be found to do their fair share of the fundamental work on which all progress must ultimately be based. We can rest assured that she is well satisfied when, as on the present occasion, our Society signals out for its highest honour one who has done not only a fair share, but also a lion's share, of most valuable fundamental work.

To the ancients the intrinsic difficulties of astronomical science did not loom large. The age of the universe meant much the same thing to them as the age of the human race, and the size of the universe was believed to be of the same order of magnitude as the size of the earth. The moon, they agreed, was about the size of the Peloponnese; the sun, as any one could see at an eclipse, was rather bigger. Aristarchus of Samos had, it is true, calculated that it must be eighteen or twenty times bigger, and had maintained that the fixed stars must be very remote indeed. But he was far in advance of his time, even believing that the earth moved round the sun. The majority of the early astronomers held that the spheres of the moon, sun, planets, and fixed stars were all packed fairly closely together. For the most part they believed firmly in the principle they described as 'the economy of Nature,' which prohibited the leaving of any unnecessary unoccupied space between the heavenly bodies—surely no scientific belief has ever been so utterly unwarranted by the facts! With this supposed principle firmly rooted in their minds, they naturally felt confident that it was a simple matter to determine the distances of the various heavenly spheres with fair accuracy. Later, when the determination did not prove so easy as had been anticipated, it began to be felt that the impossibility of discovering any parallactic motion whatever—any apparent change, that is, in the positions of the nearer stars as the earth performed its journey round the sun—presented an objection of real force against the Copernican system of astronomy.

It was on the absence of parallactic motion that Ptolemy had based his argument that the earth was the unmoving centre of all the celestial spheres, and as century after century rolled by and no trace of parallactic motion was forthcoming, it almost began to look as though Ptolemy had been right after all. Hooke, Römer, and Bradley, realising the fundamental importance of the question, attempted in turn to detect parallactic displacements of the stars, and all their efforts ended in failure, although we must remember that Bradley's failure immediately resolved itself into a triumph—the discovery of aberration. This provided convincing evidence of the earth's orbital motion, but threw no light on the question of the distances of the stars.

Early in the seventeenth century, Kepler had maintained that the stars were probably of the nature of suns, and that our sun was similar to the other stars. The observation that the brightest of the stars appear, in modern terminology, some 25 magnitudes (10^{10} times) fainter than our sun, might well have suggested that the nearest of the stars must be some 100,000 times as distant as our sun, and so must have a parallax of the order of, at most, two seconds of arc. But, so far as I know, this type of argument scarcely appeared until Newton advanced it in his "System of the World." From the observed size of Saturn's disc he calculated that the sun must emit in all $2 \cdot 1 \times 10^9$ times as much light as falls on Saturn. Although Saturn cannot re-emit all the light it receives, it appears rather brighter than a first magnitude star. Thus if the first magnitude stars are as luminous as the sun, they must be more than $\sqrt{(2 \cdot 1 \times 10^9)}$ as distant as Saturn. Newton conjectured their distance to be about 100,000 times that of Saturn, representing a parallax of $0'' \cdot 21$—that is to say, he estimated that the first magnitude stars would appear to swing through an angle of only 0·42 seconds of arc in the sky as the earth moved from one end of its orbit to the other.

---

[1] From an address delivered to the Royal Astronomical Society on Feb. 11, referring to the award of the Gold Medal of the Society to Prof. Frank Schlesinger for his work on stellar parallax and astronomical photography.

Almost at the same time the converse of this argument began to appear. Although Bradley had not succeeded in obtaining a definite parallax for any star, he had proved in 1727 that that of γ Draconis could not exceed one second of arc. Assuming this result to be generally true for all stars, astronomers began to compute lower limits to the luminosities of the brighter stars and found that they were commensurate with that of the sun, as Kepler had maintained. In 1800 Herschel used this supposition to compute hypothetical parallaxes both for bright and for faint stars.

The year 1838 saw the whole situation suddenly transformed. For in that year Bessel, Struve, and Henderson independently found definite and distinctly different parallaxes for the three stars 61 Cygni, α Lyræ, and α Centauri, and it first became possible to assert, on incontrovertible evidence, that the stars were not all at the same distance from the earth. It was now for the first time conclusively proved that the system of the stars formed a three-dimensional and not a two-dimensional structure. A workable method had been found for sounding the depths of space, and the universe lay open for exploration.

The general feeling of astronomers at the time is well shown in the address delivered by Sir John Herschel when, eighty-six years ago, he handed our gold medal to Bessel. He said: "I congratulate you and myself that we have lived to see the great and hitherto impassable barrier to our excursion into the sidereal universe, that barrier against which we have chafed so long and so vainly—*aestuantes angusto limite mundi*—almost simultaneously overleaped at three different points. It is the greatest and most glorious triumph which practical astronomy has ever witnessed. . . . Let us trust that, as the barrier has begun to yield, it will speedily be effectually prostrated."

The difficulties of the problem were so great as to put out of the question any such speedy prostration of the barrier as my predecessor of eighty-six years back appears to have hoped for. Although astronomical ability of the highest order was brought to bear, progress was slow. In 1901 Newcomb compiled a catalogue of stars of known parallaxes; their total number is only 72, of which 15 are designated as being "subject to more doubt than usual," while one is damned with four little dots which, we are told, means that it is "entirely unreliable." Even including the unreliable parallaxes, astronomy had been exploring the universe thrown open to it sixty-three years earlier at the rate of only about one star a year. The appearance of Newcomb's table, however, marked the darkest hour before the dawn.

Within two years Schlesinger begun publishing photographic determinations of parallax, which showed a far higher level of accuracy than had hitherto been either attained or thought possible. Other astronomers speedily adopted photographic methods, and in due course a scheme of co-operation was arranged between the seven observatories of Allegheny, Dearborn, Greenwich, McCormick, Mount Wilson, Sproul, and Yerkes. The results of this scheme of work up to the year 1924 are contained in Schlesinger's "General Catalogue of Parallaxes." This contains the parallaxes of 1870 stars to a very high degree of accuracy, and forms one of the most useful and valuable publications the working astronomer has ever seen. A comparison of this catalogue of 1870 parallaxes with Newcomb's 1901 Catalogue of 72 parallaxes gives a vivid picture of the work done in twenty-three years. While Newcomb's parallaxes show an average error of nearly a twentieth of a second, those in the Schlesinger catalogue seldom show a probable error of more than a hundredth of a second—the angle subtended by a pin-head at a distance of twenty miles! The gain in accuracy is the greater part of a decimal place, while the Schlesinger Catalogue contains twenty-six times as many stars as the earlier list.

Let us turn from this record of work achieved, to contemplate the realms which remain to be conquered. In measuring the distances of the stars, the natural unit of length is the 'parsec,' the distance of 19,100,000 million miles, at which a star has a parallax of one second of arc. There is no known star within one parsec of the sun. The number of known stars within spheres of radii 2, 3, 4 parsecs, drawn round the sun as centre, is 3, 6, 18 respectively. In this count binary systems are treated as single stars, although Proxima Centauri is deemed to be distinct from α Centauri, and the sun is not counted since its presence is a prerequisite to our making the calculation at all. Now if the stars in the neighbourhood of the sun were scattered at random, and were all known, the number of stars observed to lie in different spheres would be proportional to the cubes of their radii; if they were not all known, there would of course be a falling off from this law for the spheres of greatest radii, since distant stars are more likely to remain unknown than near stars. In particular, if the 18 known stars were the total inside a sphere of 4 parsecs radius, the numbers to be expected inside the three spheres of radii 2, 3, and 4 parsecs would be 2·2, 7·6, and 18 respectively. These are near enough to the actual numbers of 3, 6, and 18 to justify the hope that the great majority of the stars within 4 parsecs are known. But 4 parsecs is the greatest distance for which such a hope can be entertained. With 18 stars lying within 4 parsecs of the sun, there ought to be a further 17 lying at distances between 4 and 5 parsecs: only 6 such stars are known. There ought to be about 280 within 10 parsecs: Schlesinger's Catalogue contains only 86.

Thus even now our survey of the universe is tolerably complete only to a distance of about 4 parsecs; beyond this the number of known stars increases nothing like so rapidly as the cube of the distance. With present-day accuracy, trigonometrical parallaxes can be estimated to a probable error of, let us say, 0″·008, so that the parallaxes of stars within 100 parsecs may be said to have a real physical significance. Of such stars there ought to be about 281,250, and at the present rate of progress the determination of their parallaxes would occupy astronomy for fully 1000 years to come.

Just now we compared astronomy's past 3000 years of existence to the last tick of the clock in a dying century; we may with equal justice compare the 3000 years next to come to the first tick in a new century—such is the proportion it bears to the total time our present stars may be expected to last. Looked at on this scale there may be thought to be plenty of time for a really exhaustive survey of the universe, and past progress may be accounted amazingly rapid. In one tick of the clock astronomy has come to birth, has developed the most difficult and accurate technique known to science, and has surveyed the universe, accurately and completely to 4 parsecs, and sketchily and imperfectly beyond. The next tick of the clock should see the accurate survey extended to well beyond 100 parsecs, and astronomy has a whole century of life before it. I fear there may be a fallacy involved in the adoption of this point of view; it is that we do not know how long the human race will endure. At the very longest estimate, man has only existed for a hundred ticks of our clock, civilised man for only two or three, so that our race and civilisation would alike seem to be at the very beginning of their existence. Yet he would be a bold extrapolator who would assert with confidence that man is good for another three thousand million ticks of our clock on the ground that, if nothing unforeseen happens, the present stars will still be in existence at the end of that time. When we take a time-scale in terms of individual lives, we may still feel gratified at past progress, yet we cannot but feel awed by the magnitude of the task that remains.

On Rejuvenation.

Few human beings will view the approach of old age with philosophic calm, so that any method by which the period of maturity may be prolonged and the onset of senility delayed will always arouse widespread interest and discussion. Within the last few years a considerable amount of attention has been directed to the subject of rejuvenation, following certain somewhat sensational operations on human beings and the higher apes. Although there is no doubt that the internal secretions of the genital glands exert a pronounced effect upon the rest of the body, yet it is by no means certain that old age can be attributed solely to their degeneration: in fact, the cells of the body as a whole suffer decay, so that it is probable that an operation affecting only one of the organs of the body, only one, moreover, of the number which influence the activities of the other cells throughout life, would have no more than a temporary effect at best.

Although removal of the genital glands has a profound influence upon the mentality and bodily structure of the subject, yet evidence as to its effects upon strength and endurance has been conflicting. M. D. Sumulong, in a recent paper (*Philippine Jour. Sci.*, Mar. 1926, p. 327), from experiments on guinea-pigs, concludes that castration is without definite influence upon their pulling power or endurance. Yet one of the characteristic results of a rejuvenating operation has been the increased physical vigour of the subject, suggesting again that decay of the genital glands is not the sole factor in old age. Finally, in discussing the results of human experiments, it is difficult to know how far the element of suggestion must be taken into consideration.

Various operations have been proposed for rejuvenating purposes; thus transplantation of the gland from another individual of the same, or a closely allied, species has been effective, especially in the female. In the male, the ligation of the efferent duct from the testicular gland has been advocated as a much simpler, withal as effective, a procedure. It is of interest to note that the flatworm Planaria can be rejuvenated by starvation. It shrinks to one-quarter its adult size and becomes young again: if fed, it grows up: the process can be repeated indefinitely and the organism's life may be prolonged to twenty times the ordinary length (F. A. E. Crew, *Nineteenth Century*, Feb. 1927, p. 225). The infinitely more complex structure of the higher animals, however, prevents the recourse to such a simple expedient.

The justification for the operation of ligature of the efferent duct of the testes, or *vasoligation* as it is called, depends on the assumption that this procedure causes degeneration of the sex cells proper, thus permitting the interstitial cells to hypertrophy, with a consequent increase in the amount of the internal secretion produced by them. It might not even be necessary for them to hypertrophy: with degeneration of the sex cells the nutriment supplied to the whole gland by the blood stream might be sufficient for the full activity of the internal secretory cells, whereas with the sex cells present the former might fail to obtain all the food they required owing to the competition of the latter. In the period of full maturity both types of cells are probably sufficiently supplied by an efficient circulation.

Oslund has stated that vasoligation does not lead to degeneration of the sex cells unless the testis moves from its usual position in the scrotum into the abdomen. Y. Tamura and F. A. E. Crew, in experiments on the mouse (*Proc. Roy. Soc. Edin.*, 1926, vol. 46, p. 283), find that this operation is followed by degeneration of the sex cells, provided sufficient time has elapsed before the testis is examined. If the epididymis is removed, degeneration occurs much earlier. On the other hand, in neither case was the degeneration complete. The evidence, however, favours the assumption on which the operation of vasoligation is based.

From what has been said above, it is clear that the two functions of the testis are to a certain extent independent. Thus an individual may be rejuvenated, without at the same time becoming capable of begetting offspring. This would naturally occur if vasoligation was performed on both sides. The unilateral operation, or gland transplantation, on the other hand, might lead to renewed activity in the individual's own glands, with the production of spermatozoa and a further period of fertility.

In the female, apart from gland transplantation, which may lead to renewed activity in the individual's own ovaries, the sex cells may be destroyed by irradiation with the X-rays; in the latter case rejuvenation, due to increased activity of the interstitial cells of the ovary, is of course accompanied by sterility.

One other possible method of the future may be mentioned, and that is rejuvenation by the administration of potent extracts from the sex-glands. In the case of the female, the hormone which produces 'heat can be extracted in a, probably crude, condition from the ovaries of a number of animals and is effective on subcutaneous injection. No such active extract has yet been obtained from the testis. At any rate, the effect of the former upon the general bodily condition has not yet been studied.

By some one of these methods, used in time, it may become possible to prolong the span of life. In the case of the rat, death has been postponed for a period equal to one-fourth its average length of life. No information is available in the case of man, but it is claimed, as Crew points out, that senility in a rejuvenated individual is sudden, and death, when this phase of life is reached, soon supervenes.

Obituary.

Colonel C. H. T. Marshall.

COL. CHARLES HENRY TILSON MARSHALL died in London on Jan. 20 in his eighty-sixth year. He was born on July 8, 1841, and was the eldest son of W. Knox Marshall of Hereford. He entered the Indian Army in 1859, and on arrival in India was attached to the 35th Royal Sussex Regiment. On leaving this regiment he joined the 3rd Sikhs, Punjab Frontier Force, but saw little military service, being appointed in 1865 to the Punjab Commission. After filling various appointments with exceptional ability, he was finally made Assistant Commissioner of Lahore, retiring in 1896.

Col. Marshall was best known to Indian and other ornithologists not so much as a scientific worker but as a field naturalist. Wherever he was posted, and his districts were many, he made copious observations and notes on the local birds, and it was his extensive knowledge of game birds and his high reputation as a small-game shot that induced Hume to obtain his collaboration in the "Game Birds of India" in 1879. The three volumes composing this work are full of Marshall's field notes, and the business portion of the work, such as arrangement of plates, etc., also fell to his share. Marshall was, however, never fond of publishing his vast stores of bird lore, and never brought out any book in his own name alone for the benefit of his brother workers. At the same time, "Stray Feathers," Hume's journal of ornithology, which ran through eleven volumes, contains many of his notes, which also appeared from time to time in other Indian papers and journals. In 1877 his brother, then Capt. G. F. L. Marshall, R.E., brought out a book entitled "Bird Nesting in India," and in this volume much of the valuable information compiled was obtained from Col. Marshall. They were also associated in bringing out "The Monograph of the Capitonidæ or Scansorial Barbets," 1870. Their name has since been given to one of the most beautiful of Indian barbets, *Megalæma marshallorum*.

After his retirement in 1896 Col. Marshall returned to England, and since that date, with the exception of a few articles in English papers, he ceased to write upon ornithology. His brother, General Marshall, who survives him, is, of course, well known to ornithologists and botanists not only in India but also elsewhere. His son, Dr. G. A. K. Marshall, is now Director of the Imperial Bureau of Entomology.

We regret to record the death on Feb. 18, at Oxford, in his seventy-fifth year, of Mr. Frederick Eden Pargiter, the well-known oriental scholar. Mr. Pargiter was educated at Taunton Grammar School and Exeter College, Oxford, where he took a first class in both Moderations and the final schools. He was also Boden Sanskrit scholar. He entered the Indian Civil Service in 1876 and served as district and sessions judge and was a judge of the Calcutta High Court, retiring in 1906. He was an active member of the Asiatic Society of Bengal, of which he was successively secretary and president. On his retirement, he became closely associated with the work of the Royal Asiatic Society, serving for some years on its council and later becoming one of its vice-presidents. In his oriental studies he showed great originality. His "Dynasties of the Kali Age," published in 1913, was a work which initiated the critical study of the semi-historical, semi-legendary Puranas. This study he carried further in his annotated translation of the Markandeya Purana and "Ancient Historic Indian Tradition." He was a frequent contributor to *Epigraphia Indica* and prepared for the press the centenary volume of the Royal Asiatic Society issued in 1923.

We regret to announce the following deaths:

Dr. A. W. Crossley, F.R.S., who had just resigned the post of Director of the British Cotton Industry Research Association, on Mar. 5, aged fifty-eight years.

Dr. Ira Remsen, president emeritus of Johns Hopkins University, Baltimore, who was largely responsible for the organisation of chemical teaching and research in the United States, and was also the author of well-known text-books on chemistry, aged eighty-one years.

News and Views.

The Trustees of the British Museum have appointed Mr. Charles Tate Regan to be Director of the Natural History Departments of the British Museum in succession to Sir Sidney F. Harmer, who retired from office on Mar. 9. Mr. Regan was born in 1878 and was educated at Derby School and at Queens' College, Cambridge. He graduated with a first class in Part I. of the Natural Sciences Tripos in 1900 and obtained a second class in Part 2 in 1901. He joined the staff of the Natural History Museum in 1901 as assistant in the Department of Zoology and was placed in charge of the collection of fishes. The care of this unrivalled collection opened before him an extensive opportunity for research, of which he took full advantage, and he soon established himself as one of the leading ichthyologists of the day. He has written many memoirs on fishes—as well as reports on the fishes of Central America and the Antarctic —and is the author of a book on "British Freshwater Fishes." He was elected a fellow of the Royal Society in 1917. He was president of Section D at the Southampton meeting of the British Association in 1925, and selected "Organic Evolution" as the subject of his address. He was exempted from military service during the War on account of the important work which he was doing on the Freshwater Fish Committee. At the time when he entered the Museum, the other members of the Zoological Department were much senior to him in years, and as many of them had no desire to undertake administrative work, he secured early promotion. In 1919, on the retirement of Mr. W. R. Ogilvie-Grant, he was appointed Assistant Keeper (or Deputy Keeper, as the office is now styled), and in 1921, when Sir Sidney Harmer became Director, he succeeded him as Keeper of Zoology. He now succeeds him in the highest office of the Museum, and to him falls the task of advising the Trustees on the work of the Museum and on the course that may provide the best solution of the difficulties arising from the present congestion in the buildings at South Kensington.

With the announcement of the appointment of Mr. Tate Regan as Director of the Natural History Museum comes that of the promotion of Dr. William Thomas Calman to succeed him as Keeper of Zoology. Dr. Calman was born in 1871, and was educated at Dundee High School and at University College, Dundee, in the University of St. Andrews. He graduated B.Sc. in 1895 and D.Sc. in 1900. From 1895 until 1903 he was assistant lecturer and demonstrator in zoology at University College, Dundee, and in 1904 he was appointed assistant in charge of Crustacea in the Natural History Museum. On this subject he is a recognised authority, and is the author of many books, memoirs, and articles dealing with it: for his researches he was elected a fellow of the Royal Society in 1921. He was appointed Deputy Keeper of Zoology in 1921. He is zoological secretary of the Linnean Society and secretary of the Ray Society. Dr. Calman is a man of culture and has a wide knowledge of zoology; he may therefore be expected to stimulate the multifarious work of his Department.

Great interest has been aroused in the celebrations arranged by the Yorkshire Branch of the Mathematical Association in connexion with the two hundredth anniversary celebrations on Mar. 18-20 of the death of Sir Isaac Newton, and a large number of representative mathematicians and others have intimated their intention to participate. Close on two hundred visitors will go to Grantham for the scientific bicentenary meeting to be held at the Old School, King's School, Grantham, on Saturday morning, March 19. This is the room in which Newton studied as a schoolboy. The meeting will be presided over by Dr. J. H. Jeans, and will be addressed by the Master of Trinity, the Astronomer Royal, Prof. G. H. Hardy, and Dr. Horace Lamb. After lunch the company will visit Woolsthorpe Manor House where Newton was born, and will be entertained to tea at Stoke Rochford by Mr. Christopher Turnor. The celebration dinner in the evening will be attended by many local people; the Master of Trinity will preside, and Prof. Whittaker, the Bishops of Birmingham and Lincoln, the Master of the Mint, and others will deliver addresses. It is expected that several interesting speeches referring to Newton's life and work will be made at the dinner. The mayor of Grantham is inviting all the visitors to a civic reception at the Guildhall, Grantham, on Friday evening, Mar. 18. The mayor and other civic officials will join the visitors in a procession from the Guildhall to the Grantham Parish Church on the Sunday morning, Mar. 20, for the special bicentenary service at which the Bishop of Birmingham will preach, and the Bishop of Lincoln will also be present.

The Judicial Committee of the Privy Council has delivered judgment in the boundary dispute between Canada and Newfoundland. This involved several thousand square miles in the interior of Labrador. The dispute centred round the meaning to be attached to the expression "coast of Labrador," which in the eighteenth century was granted by proclamation and royal commission to Newfoundland. Canada contended that it referred merely to a coastal strip of sufficient depth inland to meet the needs of the fishing population, and proposed one mile from deep water as the limit. Newfoundland interpreted it as meaning all the territory drained by westward-flowing rivers. The importance of this inland elevated area lies in its timber resources and reported iron-ore deposits. Judgment has been given in favour of Newfoundland, and the boundary is defined as a line drawn due north from "Blanc Sablon Bay to the 52nd parallel of north latitude, thence westward along that parallel to the Romaine River, then northward along the left bank of that river and its head waters to their source and from thence due north to the west of the water-shed or height of land there, and from thence westward and northward along the west of the watershed of the rivers flowing into the Atlantic Ocean until it reaches Cape Chidley." Thus the whole Hamilton River system, with its floating ways for timber and its great water-power resources, is added to Labrador. The judgment is, in effect, a recognition of the principle that a coast region cannot be economically separated from its hinterland.

Prof. H. E. Armstrong delivered the Horace Brown Memorial Lecture before the members of the Institute of Brewing on Feb. 25, and was presented with the memorial medal shown in the accompanying illustration (Fig. 1). In the course of his lecture, Prof. Armstrong gave an outline of Horace Brown's life and scientific career. The feature in his early career was his devotion to the study of scientific subjects in his out-of-school time. He entered the College of Chemistry in Oxford Street, London, then under the celebrated Hofmann, in the spring of 1865. Prof. Armstrong joined the school at the same time and the two students became fast friends for life. After only six months professional training, when scarcely 17½ years old, Horace Brown entered as junior brewer into Worthington's Brewery at Burton. In 1875 he was made manager of the manufacturing department and held this post until 1889, when he became a managing director. He retired in 1893, but only to devote himself to consulting work and original inquiry. Horace Brown gradually introduced scientific methods into brewery practice and was a pioneer in making brewing subject to scientific control. His scientific researches led to his election into the Royal Society in 1899. He was awarded the Longstaff medal of the Chemical Society in 1894, a Royal medal of the Royal Society in 1903, and finally the Copley medal of that Society in 1920—the highest scientific distinction in Great Britain. He died on Feb. 6, 1925. Horace Brown's early work was built largely upon the foundation laid by the great Pasteur. An industry, the lecturer said, which has had within its fold men of such nobility of outlook and penetrative power, has reason to be proud and to take pride in its potential status among the comity of professions. The industry is one affording special opportunities of studying the life process. In instituting the lectureship, the Institute of Brewing representatives of the brewing industry have held out the right hand of fellowship to the scientific fraternity, especially to physiological inquiry.

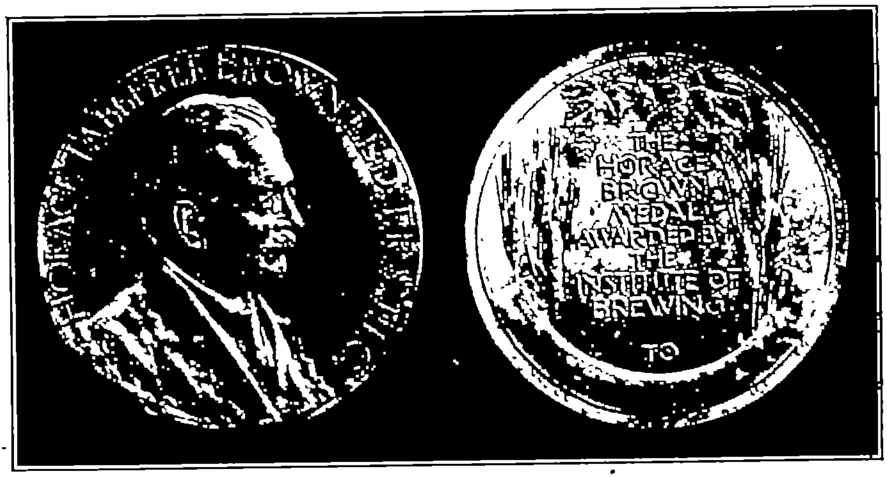

Fig 1.—Horace Brown Memorial Medal (natural size). Upon the medal presented on Feb. 25 were inscribed the words: "Henry Edward Armstrong, LL.D., F.R.S."

The subject of Prof. A. S. Eddington's eighth Gifford Lecture in the University of Edinburgh on Friday, Mar. 4, was 'World-building.' After a consideration of modern views of this subject he gave an account of some of the ideas underlying the 'new quantum theory' which could necessarily involve changes not yet formulated in the scheme of world-building. He said the conflict between quantum theory and classical theory becomes most severe in the problem of the propagation of light. Here it becomes in effect a conflict between corpuscular theory and wave theory. There is no serious doubt as to the ultimate source of the conflict; the classical (including the relativity) view of space and time is inappropriate in dealing with a single quantum. A single quantum has not travelled 50 billion miles to us from Sirius; it has not travelled for eight years. To apply these phrases to *one* quantum is like reading the Riot Act to one man. Somehow, when enough quanta are present to form a quorum, we shall be able to find among their statistical properties the genesis of the conceptions of distance and duration. But at present we are unable to make a start with such a reconstruction. As a condition for treating the subject in space and time, it seems necessary to allow that wave properties and particle properties are not inconsistent. Thus we find that in the new developments, not only do the waves of light seem to have corpuscular properties, but also reciprocally the corpuscles of matter are found to have wave properties. Long ago phenomena of diffraction of light were observed which ruled out a purely corpuscular theory of light; and it seems that, to-day, phenomena of diffraction of matter are being observed which rule out a purely corpuscular theory of matter.

In continuation of the series of lectures being delivered at Bedford College, London, Prof. H. H. Turner spoke on Mar. 1 on "Conceptions of the Cosmos in the Galilean and Newtonian Period." The period with which Prof. Turner dealt was characterised by a complete breakaway from old ideas. The beginning of the secession was evident in the work of Galileo (1564–1642) and Kepler (1571–1630), but Newton (1642–1727) crowned it by making a new orthodox system to account for the motions of the earth and the heavenly bodies. Galileo is chiefly remembered in connexion with the telescope, but he also made two great discoveries. By observation of the hanging lamp in Pisa Cathedral he found that the time of swing of a pendulum is approximately independent of the angle through which it swings. By experiments from the Leaning Tower of Pisa he found that a heavy and a light body dropped at the same instant from the same height will reach the ground almost simultaneously. This was directly contrary to the generally accepted theory, due to Aristotle, that the time of fall varies inversely as the weight of a body, and brought Galileo into conflict with the Church and the philosophers of his time. Kepler, assisted by the extraordinarily accurate observations of Tycho Brahe, contributed his three laws of planetary motion, but it was left to Newton to account for all these phenomena by his universal law of gravitation. He first proved in 1665 that Kepler's third law (on the periodic times of the planets) fitted in with the assumption of an attraction according to the inverse square law. He then proved that a heavenly body attracted in this way by the sun, will move in an ellipse with the sun at one focus. His great difficulty then was the problem of the attraction of a sphere on a body just outside it, assuming that every particle of matter attracts every other particle according to the inverse square law. It was not until 1685 that he proved, very elegantly, that a sphere attracts like a particle at its centre, and thus accounted to his satisfaction for the falling apple. The "Principia" was published in 1687 at Halley's expense, and it is largely due to his encouragement that the world was able to learn of Newton's discoveries.

A memorial tablet to the late Sir Patrick Manson, who has been aptly termed "The Father of Tropical Medicine," will be unveiled by the Minister of Health, the Right Hon. Mr. Neville Chamberlain, on Mar. 15, at 3.30 P.M., at the Royal Albert Dock Hospital. This tablet has been erected by the Seamen's Hospital Society to commemorate the great services of Sir Patrick Manson to that Society as well as to the cause of science. Sir Patrick was elected physician to the Society in 1892, and laboured almost continuously in its service for twenty years until he retired in 1912. It is a most appropriate position for this memorial in the spacious ward of the Albert Dock Hospital now known by his name, where Manson conducted his clinical teaching and where a great many of his well-known researches were carried out. It was in the Royal Albert Dock Hospital, in fact, after some seven years' intensive labour, that the London School of Tropical Medicine was founded, with the active aid and encouragement of Mr. Joseph Chamberlain; and it was the association of these two great men that has made tropical medicine stand for what it does to-day in the British Empire. It is therefore appropriate that his son, Mr. Neville Chamberlain, should unveil this memorial in the wards of the Seamen's Hospital under the auspices of that great Society which has done so much to encourage and foster the teaching of tropical medicine in Great Britain.

Some account of Manson's life and work appeared in our columns shortly after his death (May 6, 1922, p. 587). The portrait medallion in the memorial tablet is the work of Mr. T. R. Pinches, of Albert Embankment, London, and is the original plaque from which the Manson medal, now the property of the Royal Society of Tropical Medicine and Hygiene, has been struck. The original idea of a memorial medallion emanated from a committee which assembled shortly before Manson's death (April 9, 1922) to raise subscriptions from Manson's old friends and fellow-workers for a presentation portrait. After defraying expenses, the surplus of the fund was devoted to the execution of this medallion. The portrait was obtained by the artist shortly before Manson's death and is considered a specially good likeness, portraying, as it does, in a pleasing manner, the rugged but kindly face of this great teacher and investigator. It is well, now that Manson's school has been moved to the centre of London and is about to expand beyond his most ambitious dreams, that this Manson memorial should rest, where he first founded it, in the charge of the Seamen's Hospital Society at the Royal Albert Dock.

An interesting association of science with literature was approved a few days ago, when the West Sussex County Council accepted the sum of £500 as a Shelley Memorial Trust. The income from this fund is to be used for prizes to pupils in schools in the county who have been most successful in the study of science subjects, "special preference being given to boys and girls who express themselves with literary ability." Shelley was born at Field Place, near Horsham, Sussex, on Aug. 4, 1792, and the centenary of his birth was celebrated in the county in 1892. Mr. J. J. Robinson and Mr. J. Stanley Little, the trustees of the fund then raised, have now handed over the residue to the County Council for the purpose stated. It was a happy thought to establish school prizes for literary style combined with knowledge of Nature; and it is most appropriate that Shelley's name should be associated with them. His "Queen Mab," for example, and his notes upon this and other poems, reveal a knowledge of astronomy unusual in poets and of beauty in expressing it, while "The Cloud" is a perfect picture of a natural theme. Since his time, our conceptions of the universe, and of the constitution of the radiant orbs in it, have been greatly extended, but there is only one poet to-day—Mr. Alfred Noyes—who has found in it a source of inspiration. We welcome, therefore, the encouragement to be given to young people in Sussex to think of truth and beauty together instead of things apart.

SIR HERBERT JACKSON delivered the Friday evening discourse at the Royal Institution on Mar. 4, when he discussed some colouring agents in glasses and glazes. Out of a large number of colouring agents for glasses and glazes, copper and iron were chosen as illustrations. Metallic copper dispersed through a glass in an extremely fine state of division gives a clear transparent red glass. With progressively larger particles a semi-transparent red glass can be obtained or a glass which is blue to look through and red-brown by reflected light. With still larger particles the glass in thin layers is of a grey neutral by transmitted light and a pronounced brown-red by reflected light. Cuprous oxide was used by the Egyptians to produce a brilliant scarlet glass, the colour of which is due to comparatively large crystals of cuprous oxide. Specimens of early glass, presumably of Saxon origin and of an orange-yellow colour, also owe their colour to cuprous oxide, but in its yellow form. Only recently has it been possible to reproduce these glasses on a laboratory scale. The colours produced by cupric oxide are transparent blues and greens, the precise colour being determined by the amount of cupric oxide present, the composition of the glass, and the temperature at which it is made. Ferric oxide gives yellows, browns, and brownish reds, which are attributed to various concentrations and states of dispersion of this oxide. Ferrous oxide as a colouring agent produces blues and greens according to the composition of the glass, and to it can be attributed the beautiful tints found in certain Chinese glazes. Ferroso-ferric oxide (magnetic oxide of iron) gives neutral tints of various depths, and with high concentrations a black glass can be obtained. If the concentration of the oxide be high enough, some of the oxide will come out in cooling so as to be dispersed through the glass in very minute aggregations, which are, however, presumably crystalline, since the resulting glass is appreciably magnetic.

MR. T. L. ECKERSLEY, who has for several years been experimenting on short-waves for the Marconi Co., read an important paper on short-wave radio telegraphy to the Institution of Electrical Engineers (Wireless Section) on Mar. 2. As the paper is both theoretical and experimental, it will prove of interest to many. The agreement between practice and the ordinary theory is far from satisfactory. Some propose to use aerials which radiate their energy upwards so as to take advantage of the conducting layer. The Marconi Co. radiates its beam horizontally with a vertical polarisation. Some Americans prefer to use a horizontal polarisation. The author's experiments seem to indicate that low-angle transmission, that is, almost horizontal radiation, is the best. Cases have been known where the ray comes right round the world and affects a receiver relatively close to the transmitter. The ray which has gone round the world causes an echo which is heard about a seventh of a second behind the main signal. Experiments with very short wave-lengths prove that an aerial 7 metres in height is much less efficient than aerials of 35 metres and 70 metres height respectively. With low wave-lengths the author finds that the range increases very definitely with the square of the frequency, provided the wave-length is greater than 10 metres. At this wave-length, signals projected at a fairly high angle in Great Britain have little if any effect on a receiver at Buenos Ayres. They seem to leave the earth altogether. There is little doubt that the daylight range is a minimum for waves 200 metres in length. He concludes that in long-distance transmission the ray trajectory has a shallow angle of elevation of about 15° and follows the great circle path. His theory is essentially a modified form of the conducting layer theory.

THE British Museum (Natural History), to use the awkward official title, has issued the first number of a *Natural History Magazine*, designed to further natural knowledge by descriptions of important additions to the collections and of notable possessions in the galleries and cabinets. It is a welcome sign, taken with the creation of popular exhibits, the institution of popular demonstrations, and the issue of a wonderful series of picture post-cards, of the will of the Trustees to make special appeal to the intelligent but non-scientific public whose moneys support the institution. The first number contains a variety of articles dealing with particular items in the departments of zoology, entomology, geology, and botany—"Two Important Additions to the Collections of Beetles," "Tektites," "Rafflesia: the largest known Flower," "Sirens in Fancy and in Fact," to mention the first four. The articles are short and informative; they are severely limited in scope and are largely descriptive, so descriptive as to suggest occasionally the flavour of the text-book. The success of the magazine depends, we take it, upon the support of the public, and the public, greedy as it is nowadays of natural history information, demands the general as well as the particular, and above all likes the light touch. We suggest that at least one article in each number be reserved for a general theme, such as the exhibits are well fitted to illustrate, heredity, protective, sexual, or seasonal coloration, migration of fishes, or a score of others, and that too narrow a view should not be taken of the way in which the collections and the work of the staff can be best advertised. There could be no better model of a successful, attractive, and purposeful museum magazine than the parallel publication, *Natural History*, issued by the American Museum of Natural History.

CONFLICTING reports as to the extent of the earthquake which occurred in Japan on Monday, Mar. 7, at 6.28 P.M., have been received. It seems that a severe shock lasting about three minutes was felt in Nagoya, Kyoto, Osaka, and Kobe. In Osaka and Kobe, fires broke out and sea waves following the earthquake added to the disaster. A number of smaller towns have been destroyed. The seat of the disturbance appears to have been in the provinces of Tajima and Tango on the north side of the main island, Honshiu, some two hundred miles west of Tokyo and about fifty miles north of Kobe.

Prof. H. H. Turner, Savilian professor of astronomy at the University of Oxford, has been awarded the Bruce Gold Medal of the Astronomical Society of the Pacific, "for distinguished services to astronomy."

The Secretary of State has appointed the following as members of a joint committee for the management of the proposed Dairy Research Institute in Scotland: Sir Donald MacAlister (chairman); Prof. Robert Muir and Prof. D. Noël Paton, representing the University of Glasgow; Mr. C. Lindsay, Mr. John Speir, and Principal W. G. R. Paterson, representing the West of Scotland Agricultural College; the Right Hon. Lord Weir; and Mrs. Houison Craufurd.

Dr. W. Lawrence Balls has been appointed Director of the Botanical Section of the Egyptian Ministry of Agriculture. Meanwhile Dr. Balls is paying a short preliminary visit to Egypt, at the invitation of the Royal Agricultural Society, to advise that body on a proposed cotton research institute. It is of interest to recall that both these developments are the outcome of Dr. Ball's activities in the years 1904–14.

In an article in *Scientia* of January last on the dawn of modern biology, the tercentenary is commemorated of the birth of the illustrious and observant Italian biologist Francesco Redi. The long prevalent view that flies were generated in putrefying flesh was demolished by a few simple but fundamental experiments of Redi, who proved for the first time that the maggots in putrefying flesh were the product of eggs laid thereon by flies which visited it—a notable beginning of the long attack on the doctrine of spontaneous generation.

The managing director of the Amalgamated Wireless (Australasia) Ltd., telegraphs to the Marconi Co. that during the past three weeks the beam wireless station has been readjusted and now gives most satisfactory results. During two days, beam signals have been heard in Australia throughout the 24 hours. Two-way communication also at high speeds has been established daily for several hours on end, the maximum speeds equalling those obtained over the relatively short distance between England and Canada. During a continuous test of seven days, the average traffic capacity exceeded 60,000 words per day in each direction. As soon as the British official tests are completed, the service will be open for public traffic. The transmitting and receiving stations in England are at Grimsby and Skegness respectively; the Australian stations are near Melbourne.

The Prize Thesis submitted to the University of Edinburgh no less than sixty-seven years ago by Prof. W. Carmichael McIntosh has been reprinted (by Messrs. Paul and Matthew, Dundee, 1926). It is entitled "Observations and Experiments on Carcinus mænas," and it includes some most interesting notes on the natural history of this familiar crab. It contains also an account of the anatomy of the central nervous system, with observations on the effects of operative interference with the parts of these organs. A most curious description of the action of a number of narcotic and other poisonous substances on the living animal follows. There are four lithographic plates, which were drawn on the stone by the author. We congratulate Prof. McIntosh on this remarkable piece of research. There must be few scientific workers, still actively employed, who can look back on substantial investigation carried out so many years ago.

A discussion on the problem of the humane slaughtering of animals was held on Feb. 25 at King's College, London, under the auspices of the newly formed University of London Animal Welfare Society. Prof. Julian Huxley, who presided, contrasted the up-to-date public abattoir in which he had had occasion to work at Heidelberg with the old-fashioned little private slaughter-houses of Oxford, and Profs. J. M'Cunn and A. R. Smythe, of the Royal Veterinary College, while differing on minor points, agreed in recommending the use of the captive-bolt pistol as more humane than the old-fashioned methods employed in the case of 90 per cent. of the animals slaughtered in Great Britain. That view was vigorously opposed by a representative of the meat trades, but a resolution was passed calling upon the Government to appoint a commission of inquiry into the whole question.

At the forty-ninth annual general meeting of the Institute of Chemistry, held at 30 Russell Square, Prof. G. G. Henderson, president of the Institute, remarked that there appeared to be some abatement of the enthusiasm for chemistry as a career which was noted immediately after the War, although the roll of membership had increased by 242 during the past year, to a total of more than 5200. At present the supply of chemists in Great Britain exceeds the demand. In October next the Institute will celebrate its jubilee, and a medal and prize have been established in honour of the first president, Sir Edward Frankland, who held office from 1877 until 1880; the award will be made to a registered student of the Institute for the best essay on a set subject of professional, as opposed to technical or purely chemical, importance. The subject for the first essay will be "The Importance of Chemistry to the Welfare of the People." Prof. Arthur Smithells has been elected president of the Institute for the period 1927–28.

At a meeting of the Newcomen Society on Feb. 22, held at the Institution of Mechanical Engineers, papers were read by two French members, MM. Seguin and Achard, one dealing with "British Railways of 1825 as seen by Marc Seguin," and the other with "The First British Locomotives of the St. Etienne-Lyon Railway." Marc Seguin (1786–1875), nephew of Montgolfier, was one of the best-known engineers of the day, and papers and notebooks of his preserved at the family seat at Varagnes, near

Annonay, contain an interesting account of a visit he made to England in 1825, the year of the opening of the Stockton and Darlington Railway. Seguin met Brunel, Maudslay, Babbage, Stephenson, and Brewster, and travelled to Leeds, Newcastle, Edinburgh, and Liverpool. He himself was concerned at that time with a project for steam navigation on the Rhone, and the main object of his visit was to obtain engines. He saw, however, a good deal of the early mine railroads of England, while his account of the Stockton and Darlington railway is of great historical value. Sequin was connected with the St. Etienne-Lyon Railway and was an independent inventor of the tubular boiler.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant for technical records work at the Building Research Station of the Department of Scientific and Industrial Research—The Director, Building Research Station, Garston, near Watford, Herts (Mar. 21). A laboratory assistant at the Chemical Research Laboratory, Teddington—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1 (Mar. 21). A lecturer in the chemical and metallurgical department of the Wolverhampton and Staffordshire Technical College, and a lecturer in engineering subjects at the same institution—The Clerk to the Governors, North Street, Wolverhampton (Mar. 25). Lecturers in the spinning and weaving departments of Keighley Technical College—The Secretary, Education Offices, Keighley (Mar. 26). An assistant curator of the Leeds City Museum—The Town Clerk, 26 Great George Street, Leeds (Mar. 28). Professors of mathematics, and education and psychology at Raffles College, Singapore—The Secretary, Board of Education, Whitehall, S.W.1 (Mar. 28). An assistant in the department of archæology, Free Public Museums, Liverpool—Dr. J. J. Simpson, Free Public Museums, Liverpool (April 2). A woman professor of physiology at the Lady Hardinge Medical College, Delhi—The Honorary Secretary, U.K. Branch Dufferin Fund, c/o Major-General J. B. Smith, India Office, Whitehall, S.W.1 (April 19). A graduate for engineering subjects and mathematics at the Workington County Technical and Secondary School—The Principal.

Our Astronomical Column.

RETURN OF THE COMET PONS-WINNECKE.—This comet was detected by Prof. G. von Biesbroeck at Yerkes on Mar. $3^d\ 10^h\ 19{\cdot}5^m$ U.T., in R.A. $14^h\ 12^m\ 20{\cdot}4^s$, N. Decl. 25° 45′ 24″ (1927·0), magnitude 16·0. With the aid of this observation, and using the following elements, which are those of Mr. C. J. Merfield slightly modified, Dr. A. C. D. Crommelin has calculated the following ephemeris:

$$\begin{array}{l} T = 1927 \text{ June } 21{\cdot}1564 \text{ U.T.} \\ \left.\begin{array}{l} \omega = 170^\circ\ 22'\ 50'' \\ \Omega = 98\ \ \ 10\ \ \ \ 0 \\ i = 18\ \ \ 57\ \ \ \ 0 \end{array}\right\} 1927{\cdot}0 \\ \log q = 0{\cdot}016840 \\ e = 0{\cdot}685516 \\ \text{Period} = 6{\cdot}00983 \text{ years} \end{array}$$

EPHEMERIS FOR 0^h U.T.

	R.A.	N. Decl.	log r.	log Δ.
Mar. 13.	$14^h\ 23^m\ 23^s$	29° 5′		9·9410
17.	14 27 37	30 36	0·2106	9·9173
21.	14 31 34	32 11		9·8938
25.	14 35 23	33 49	0·1914	9·8703
29.	14 38 47	35 30		9·8467

T is 0·6 days later than Mr. Merfield's prediction.

The comet will make a very close approach to the earth in June, being at its nearest (3·6 million miles) about 0^h on June 27. Its parallax will then be 227″, and it will be well placed for observation, being on the meridian at 3^h A.M. in North Decl. 6°. Its daily motion will then be 11°·7, which is just equal to that of the moon in apogee. It should be readily visible to the naked eye, but may be rather difficult to observe for position in the telescope, as it will fill most of the field. The presence of a stellar nucleus is not very probable, but if there should be one, the occasion should be utilised for deducing the solar parallax.

THE FIREBALL OF FEB. 25.—Mr. W. F. Denning writes: "The observations of this brilliant object, though for the most part incomplete in scientific details, yet include some excellent descriptions and enable the real path to be determined with satisfactory accuracy. Seventy-four accounts were received, ranging from Leicester in the north of England, Sandwich on the east, Portland in the south, and Plymouth and Penzance on the south-east. That the object detonated rests on the testimony of about half of the observers.

"The radiant point was in Leo at 144° + 6° and the height of the meteor was 65 to 27 miles, path 54 miles, velocity 18 miles per second. These results are slightly different from those derived from the preliminary investigation.—The path was over Devon from about Kingsbridge to north of Dawlish. This shower from near o Leonis is visible from November until February. At any rate radiation is maintained from apparently the same point.

"The fireball was chiefly remarkable for the vividness of its intensely white light and for its double outburst. Many large meteors display very long paths from radiants near the horizon, but this object was comparatively near to its point of emanation."

THE ORBIT OF 61 CYGNI.—This double star has always excited great interest, since it was the first to have its parallax determined by Bessel. The duplicity was discovered by Bradley in 1753, and measures were obtained by Ch. Mayer, Sir W. Herschel, and later by Bessel. The latter ventured to assign the period of 460 years, but in the course of time it became clear that this period was considerably too short. Not a few astronomers (among them C. Flammarion and Burnham) questioned the orbital nature of the motion, and considered that it could be represented by a straight line. But Mr. T. Lewis, in his memoir on the Struve double stars, gave a large diagram which made the curvature palpable and obvious. P. Baize contributes an interesting article to *L'Astronomie* for January, into which he brings Mr. Lewis's diagram, with the addition of twenty more years of observations which have still further established the curvature. He makes a re-determination of the orbit, reaching results quite close to those given by Peters in 1883; the periods found are, Peters 783 years, Baize 756 years, so we may perhaps consider it as known within a century or so. Baize's other elements are: Periastron A.D. 1978, inclination 45°, eccentricity 0·013, semi-major axis 32″·8. Taking the parallax as 0″·28, the mean distance is 117 units, which would give a period of 1266 years if the joint mass was equal to that of the sun. The period 756 years, therefore, indicates a joint mass considerably in excess of that of the sun.

Research Items.

A Bronze Age Tumulus at Dunstable.—*Man* for February contains a report of the opening of one of the barrows (No. 5) of the "Five Knolls Tumuli" at Dunstable by the University College and Hospital Anthropological Society of London. This is the most northerly of the mounds. It is regular in shape, with a diameter of 50 ft. and a height of 5 ft. The remains of thirteen individuals were discovered. With one exception, those skeletons which showed no sign of disturbance were buried in the extended position with the head raised. The one exception was that of a female of Mediterranean type which lay in a crouched position in an oval cist cut into the chalk, the sole furniture being a flint knife. The skull showed a remarkable advanced symmetrical thinning. This feature is discussed by Prof. Elliot Smith in a note, in which he points out that this peculiarity is rare in Europe but common in the aristocracy of ancient Egypt from the third to the nineteenth dynasties. The only features common to the other skeletons from the barrow are presented by the limb bones. The cranial forms vary, though within narrow limits, being all mesaticephalic. In the lower limbs the femurs are all platymeric. Remains of two cremation burials were found, one accompanied by a cinerary urn of late bronze age type, which it may be assumed is of later date than the burial by inhumation near which it was found.

Rock Paintings from the Central Sahara.—Dr. P. Durand and M. L. Lavauden describe in Vol. 36, No. 5-6, of *L'Anthropologie* some hitherto unpublished rock paintings in the cave of In-Ezzan, Central Sahara, a little to the north of the Tropic of Cancer. This cave, situated in a circle of rocks from which issues a subterranean stream, is about 1700 kilometres south-east of the Straits of Gibraltar. It has been a halting-place for the nomads of the region from times immemorial. The paintings are executed in white and red, while certain missing details may once have been shown in a black which has now disappeared owing to the perishable nature of the charcoal or other form of black pigment used. The paintings are obviously of very different ages. The question of their date and affinities are discussed in an appended note by the Abbé Breuil, who classifies the pictures and inscriptions into ten categories. Of these the oldest are nude human figures, male and female, accompanied by tree or palmlike forms; one man carries a bow, and with him seem to be associated figures of oryx in white and red. A man clothed and bulls closely resemble figures of the Spanish paintings of Cogul. In another class are human forms, clothed, more schematic in design than the human figure last mentioned but with the same type of clothing, part of which is a kilt recalling the early Egyptian costume. These figures are accompanied by hounds of Asiatic type. Paintings in both white and red show Arab horsemen, hunting scenes, and a man mounted and armed with a long lance. The style, especially of the horses, suggests Sassanid art, and is evidently comparatively modern, as also are the inscriptions in Arabic. Apart from the groups which are evidently modern, the paintings present a great diversity of style and date, and morphologically recall now the art of the Bushman, now that of eastern Spain, and now that of predynastic Egypt.

Brewing in Babylon and Egypt.—The Society of History and Bibliography of Brewing of Berlin has recently published the results of the first of a series of investigations on beer and brewing by the peoples of ancient civilisations ("Bier und Bierbereitung bei den Völkern der Urzeit," 1. Babylonien und Agyptien. Berlin, 1926). The art of brewing has now been traced back to 7000 B.C., when brewing was a common household occupation of the peoples of the valleys of the Tigris and Euphrates. Dr. E. Huber shows that the beer of the day also played an important part in the social and religious life of this period. Definite rations of beer were allotted to each class of workman, and it was also used as an offering to the gods and as a diluent in medicine. The evidence in support of the cultivation and use in brewing at this time of Emmer wheat and of barley is of particular interest in view of the recent correspondence in Nature. By 5000 B.C. brewing businesses existed, often on a large scale. It is uncertain whether hops were used in Egyptian times, though there is evidence of the use of other flavouring herbs such as rue and safflower. The publication is profusely illustrated with photographs of Babylonian seal cylinders, chiefly of the time of Hamurabi, and of inscriptions and bas-reliefs from Egyptian tombs. A number of the latter are pieced together to form twenty-three scenes describing the complete brewing process. Dr. M. Phillipe contributes discussions of the brewing technique of these periods.

Scottish Sea Trout.—In a paper on the sea trout of the River Ailort and Loch Eilt (*Fisheries, Scotland, Salmon Fish.*, 1926, 3 (June 1, 1926)) Mr. G. H. Nall summarises the results deduced from figures and tables contained in an unpublished report. 1692 sets of scales, mostly between April and October 1925, were taken from fish varying in weight from a few ounces to 12 lb., and in age from 2¼ years to 12¼ years. Two fish, each of 12 lb., were in their thirteenth year, having both had 3 years of parr life, 2 years in the sea without spawning, and then spawned in seven successive winters. An interesting feature was the big run of heavy fish very early in the season in fat condition, with remarkably strong growth in the opening months of the year. An examination of the scales for 'slow growth' and 'rapid growth' zones indicated that these fish started rapid growth in December or January; growth ceased on entering fresh water, although the period of heavy feeding and rapid growth for the majority of fish was between spring and mid-August. There were indications that fish of the same smolt age tend to descend to salt water in company and remain together in homogeneous shoals during early sea life. Interesting comparisons are made between these sea trout and those from other districts in Scotland, which point to the fact that the farther north the district the longer the parr life and the later the approach of maturity. In the Ailort district, two-thirds of the smolts migrated after 3 years of river life, and there was a tendency for the older smolts after migration to mature earlier in life than the younger smolts.

Marine Biology in the Pacific.—In publications on "Marine Zoology of the Tropical Central Pacific" (Bernice P. Bishop Museum, Bulletin 26 and 27. *Tanager* Expedition Publications Nos. 1 and 2, 1925) results obtained on the *Tanager* Expedition of 1923–24 are given. This expedition was organised under the auspices of the U.S. Navy, the National Research Council, the U.S. Biological Survey, and the Bernice P. Bishop Museum. A survey was made of the thirteen islands of the Hawaiian group, extending north-east from Kauai to Ocean Island, and also of Johnston and Wake Islands. The work opens with an account by C. H. Edmondson of the Crustacea, in which 12 new species are described and figured and notes on distribution given, including a considerable number of new records for the North Pacific Ocean. W. K. Fisher deals with the sea stars, describing two new species and giving valuable information on the composition and distribution of the fauna. The remaining echinoderms are reported on by H. Lyman Clark. A short account of the polychætous annelids by A. L. Treadwell, with a description of two new species, is included; the specimens were, however, rather few owing to unsuitable methods of collection. This first publication concludes with a chapter by J. A. Cushman on the Foraminifera collected on the expedition. Photographic reproductions of some of the species described in the above articles are given. H. W. Fowler and J. C. Ball describe the fishes of Hawaii, Johnston Island, and Wake Island.

THE CILIATED CELLS OF THE GILL OF MYTILUS.—D. Bhatia has examined the structure of the latero-frontal cells of the gills of Mytilus (*Quar. Jour. Micr. Sci.*, vol. 70, Part 4, Dec. 1926). Between the corresponding cells of American species of Mya, Lampsilis, and Quadrula, Grave and Schmitt (1925) observed inter- and intra-cellular fibrils which they suggested represent paths for the conduction of stimuli from cell to cell and for co-ordination of the epithelium. Bhatia emphasises the importance of careful sectioning of the epithelium so as to display the whole extent of the cell and its intracellular fibrils. Each latero-frontal cell bears a pair of cilia which, as Carter showed, are loosely united. The exposed surface of the epithelium is covered with a continuous gelatinous cuticle with a wavy outline through which the cilia pass at the crests. Each cilium, which has a small microsome at its base where it enters the cytoplasm, *i.e.* immediately below the cuticle, divides into two rootlets, right and left (*r*, *l*, and *r′*, *l′*). The *r*, *r′* and *l*, *l′* rootlets gradually converge and near the nucleus fuse to form single fibrils which pass respectively right and left of the nucleus, unite in the base of the cell, and are firmly attached to the subepithelial layer. It is suggested that fibrils described by Grave and Schmitt as connecting adjacent pairs of microsomes are the inner edge of the cuticle. The author, while stating that his observations do not throw any new light on the function of the ciliary rootlets, thinks it is probable that the co-ordination of movement is effected by cell contact rather than by any specialised fibrillar mechanism.

FACTORS OF BIRD MIGRATION.—It has usually been assumed that either food or temperature, or a combination of both, released the migratory instinct; but a recent paper by Prof. William Rowan (" On Photoperiodism, Reproductive Periodicity, and the Annual Migrations of Birds and Certain Fishes," *Proceedings of the Boston Society of Natural History*, vol. 38, No. 6, pp. 147-189) points out that neither of these are of sufficiently regular recurrence to account for the extraordinary accuracy of arrival-date in a number of migrating species. The only environmental factor which would seem to fulfil the necessary conditions is length of daylight; and the bulk of the paper is devoted to a discussion of the possible influence of this. The author's case is of course strengthened by reference to the well-known and important discoveries concerning the influence of day-length upon plants, an influence first properly investigated by Garner and Allard in 1920. If such extraordinary effects upon rate of growth and time of flowering can be exerted by this agency in plants, there is every reason for suspecting that it may be operative in animals also. In birds it might operate directly, or indirectly through length of time available for feeding. In addition to a critical summary and discussion, Rowan refers to the results of his experimental investigations on the subject, of which a preliminary report appeared in NATURE (115, 494; 1925). He has definitely established that an increase of 'day' in autumn, produced by artificial illuminations after dark, will cause precocious growth of gonads (accompanied in the males by song) in the dead of a Canadian winter, in species which normally migrate southwards in early autumn. He has further established that control birds liberated in mid-winter when their gonads were at minimum size do not migrate southwards, while light-exposed birds whose gonads are beginning to enlarge, if liberated at the same time, disappear: one may, with the author, surmise that the light has so upset their normal endocrine equilibrium that they move northwards in spite of the arctic conditions. It therefore appears quite probable that relative length of day and light, acting via the gonads, determines the onset of migration.

LEAF STRUCTURES AND WOUND RESPONSE.—Although the healing of wounds in stems has provided a fruitful subject of investigation for numerous botanists, wound response in the leaf has so far received much less attention, and so it is of considerable interest to read the results of Prof. R. B. Wylie's experiments (*Science*, vol. 65, No. 473, Jan. 21, 1927). He considers that the thin structure of most leaves makes them well fitted morphologically for healing, on account of the comparatively small area of tissue exposed following lesion. Wounds made on leaves by removing circular areas with a punch are first of all closed up by a pseudocicatrice formed mainly from the collapsed thin-walled mesophyll cells damaged in punching. With the collapse of the interior cells, the upper and lower epidermal layers curve over and may even overlap, thus giving the wounded leaf a rounded edge. Certain secretions such as latex, gums, and resins may add efficiency to this preliminary barricade against water loss. One of the functions of the pseudocicatrice is considered by the author to be stimulation of the underlying tissues to the development of the cicatrice proper, which is formed by what corresponds to a phellogen layer developed by tangential divisions immediately behind the pseudocicatrice. Even the highly specialised epidermal layers respond by prompt mitosis, dividing by means of vertical walls only, a phenomenon one would scarcely expect in the very thick and heavily cutinised epidermal cells of sclerophyllous evergreen types. In brief, all cell layers of the leaf blade share in building up new protective tissue, and the cicatrice proper shows greater uniformity of cell size and content than the several cell elements which through mitosis have contributed to its formation. The cell walls in the cicatrice tissue are also usually modified chemically, and very early in its development the presence of lignin can be demonstrated behind the wounded margins. Wound healing may be complete in ten to twenty days, according to the particular species involved.

COMPASS VARIATION IN CANADA.—Bulletin 58 of the Topographical Survey of Canada (price 10 cents) is entitled "The March of the Compass in Canada, and Daily Variation Tables." The author, W. H. Herbert, gives a very interesting and well-written account of the secular change and daily variation of the compass declination, and their importance for all who make use of the compass in practical life. For nearly all the early land surveys in Canada the boundaries were defined in the deeds by compass bearings, and in order to re-trace and re-establish these old boundaries, and to link together old surveys, it is desirable to have trustworthy and accessible information as to the past and present secular variation of declination throughout Canada. The Bulletin, therefore, which is prepared primarily for compass users, gives tables of the declination at 126 well-distributed stations for every tenth year from 1750 onwards (when data are available) to 1900, and thereafter for every fifth year to 1925. At many of the stations the earliest data are for 1820 or 1880. These tables thus indicate the secular variation at the corresponding stations and the regions around them. Tables of the average diurnal variation of declination, which must be taken into account in accurate surveying by compass, are also given for 24 stations for the summer, winter, and equinoctial seasons. Detailed examples of the use of the tables are given. The Bulletin should interest and help all who, for duty or pleasure, have occasion to travel off the beaten track in Canada.

GOLD COAST SURVEY.—The Report of the Survey Department of the Gold Coast for the year 1925–26 shows a record of continued progress in actual field work, in the training of surveyors and draughtsmen and the publication of further sheets of the topographical map. The surveys are now completed of the whole of the Gold Coast Colony, the greater part of Ashanti, and the eastern part of the Northern Territories. During the present year work is on hand in the Northern Territories, the western frontier of Ashanti, and the mandated territory of Togoland. It is of interest to note that the map sheets are now all printed in Accra instead of in Britain. The report includes a layer-coloured map of the southern part of the Gold Coast on a scale of 1 to 500,000, which shows the excellence of the local colour printing and technique.

HEATS OF ADSORPTION ON CHARCOAL.—The heats of adsorption of oxygen, chlorine, carbon dioxide, ammonia, ether, chloropicrin, and water on charcoal at 0° have been measured by F. G. Keyes and M. J. Marshall. The ice calorimeter was employed, and the charcoal was contained in an evacuated quartz tube. In every case a large initial adsorption was noticed, which rapidly fell to a constant value with increasing concentration. Interesting conclusions are drawn from the detailed results, which appear in the *Journal of the American Chemical Society* for January 1927. The adsorbed vapour is considered to be in a special state, and only the first layer is directly influenced by the adsorbent. Because of this special state, the first layers form new adsorbing surfaces which adsorb molecules of the same kind. This special state becomes less pronounced with each succeeding layer, and finally a layer is reached in which the molecular arrangement corresponds to ordinary contact.

PROPAGATION OF SOUND IN WIDE PIPES.—In the December number of the *Annales de Physique*, M. Th. Vautier describes a repetition of Regnault's classical researches on the propagation of sound in wide pipes. The pipe chosen for these experiments was a conduit intended for water. It was one metre in diameter, made of cast iron, and placed under the pavement of the Cours Gambetta, Lyons. A section of this conduit, of length 1640 metres, was available for the experiments. The ends of the section were closed with wooden planks, and a gap at one end of the section allowed the insertion of recording instruments. The latter consisted either of rubber membranes or suspended mirrors or microphones, which, owing to their inertia, could only be used to register the passage of the waves and not their form. Records of the form of the waves are promised in a later memoir dealing with records obtained by an interferometer method. The source of the sound impulse was a pistol or a powerful spark from an electrostatic machine. Vautier gives numerous oscillograms which indicate the response of the recording apparatus. Reduced to dry air at 0° C., the velocity of sound found in these experiments was 330·54±0·5 metres per second. The value obtained by Regnault with a conduit 1·1 metre in diameter was 330·45 metres per second. The value obtained by Esclangon as the mean of a large number of experiments in the open air carried out during the War, was 330·9 metres per second.

CARBON ASSIMILATION.—In *Scientia*, vol. 41, Feb. 1927, Prof. Walter Stiles gives a lucid and closely reasoned review of the present state of our knowledge and conceptions of the mechanism of carbon assimilation in plants. He considers the conclusions regarding the process of photosynthesis arrived at by various chemical investigators invalid, on the ground that they are based on experiments conducted *in vitro*, and form no criterion of the actual processes going on in the plant amid the complex of physiological factors found in the actual protoplasm itself. So long ago as 1861, Butlerow was able to produce a sugar-containing substance from a derivative of formaldehyde, and there seems no doubt that formaldehyde can be produced from carbon dioxide and water, and sugar from formaldehyde, without the aid of the living green plant, but this constitutes no evidence that the course of synthesis *in vivo* follows on the same lines. Even the theory of Willstätter and Stoll, based on physiological work with living plant material, assumes the formation of formaldehyde as an intermediate product in photosynthesis, though the evidence for the presence of that substance in plants is of a very slim kind. Some considerations are adduced for concluding that the complete photosynthetic process must comprise both a photochemical stage and a 'dark' chemical stage in which light is not involved. Willstätter and Stoll thought the chemical stage was controlled by some enzymatic factor, and there is considerable evidence supporting this hypothesis. The problem of changing radiant energy to chemical energy in the assimilating cell is closely bound up with the function of the four leaf pigments, chlorophyll-*a*, chlorophyll-*b*, carotin, and xanthophyll, but no completely convincing explanation of the rôles of all four pigments has yet been given. While a satisfactory understanding of the mechanism of carbon assimilation is so far nonexistent, knowledge on the subject is becoming fuller and clearer, but a complete solution of the problem will require the co-operation of workers in the three fields of botany, chemistry, and physics.

ULTRA-VIOLET THERAPY APPARATUS.—Messrs. Watson and Sons (Electro-medical), Ltd., have issued a new edition of their booklet on "Artificial Sunlight" as Bulletin No. 80. The first 10 pages are devoted to a brief account of the nature of ultra-violet rays, their method of production, and their properties; the remaining 36 pages contain a detailed account of the various sources of artificial sunlight now available. The illustrations are very good, and show how quickly the various medical needs of a technical character are being met by manufacturers. There is scarcely a part of the body for which some special piece of apparatus has not been designed, for the administration of ultra-violet rays to it. The booklet includes also an account of devices for the measurement of the rays when used clinically. There is no unanimity yet as to the best method to be adopted for this purpose, but in the meantime medical men will be glad to know of the selection that does exist.

Science in Japan.

By Prof. C. COLERIDGE FARR, Christchurch College, Canterbury, N.Z.

AS a delegate from the New Zealand Institute I had the honour and great pleasure to visit Japan on the occasion of the third Pan-Pacific Scientific Congress which was held there in October and November last, and an account of that visit may be of interest. As a physicist, and from a scientific point of view, I confined my attention solely to physics, geophysics, and cognate branches of knowledge; and I must leave other delegates to make such remarks as they may think necessary on the branches of science which interested them. Before dealing with the main subject of this article, however, I desire to make several observations of a general character.

ORGANISATION.—The organisation of the meeting was remarkable for its completeness and thoroughness, and is a great credit to those who had to do with its development. On entering Japanese waters at Nagasaki, a port at least 850 miles from the city of Tokyo, where the meeting was held, we were met by an emissary from the Conference, Dr. Oshima, and from then until the moment of sailing again from the same port four weeks later, we were not without the assistance of honorary guides, who were Japanese gentlemen who could speak English fluently. I believe similar guides met every party arriving from oversea at their port of arrival, and that each party was also 'shepherded' in the same way as we were throughout the tour. The amount of strenuous effort on the part of the guides must have been tremendous. They took control of all the baggage—and I did not hear of a single instance of loss—they made all the necessary arrangements regarding sleeping berths in the trains, they provided meals where the travelling was done in trains which had no dining-car—in fact they saw to all details, and seemed to leave nothing whatever to chance. The benefit of this in a land with a foreign and absolutely unknown language cannot be imagined, and only became apparent to us on those occasions when—breaking away from our guides—we attempted to make our own way about in some of the cities. Progress then, if not impossible, became exceedingly slow. The people one met were courtesy itself but could not understand what we wanted, nor could we understand their answers, and it was therefore necessary to light at length upon some person who did understand something of the language one was speaking.

In all other respects the organisation of the meeting was at an equally high level.

JAPANESE COURTESY.—Perhaps it may not be out of place to make a few observations upon this delightful feature of Japanese life which impressed itself upon so many of us upon numerous occasions. The Japanese seem—as was stated by a speaker at one of the functions that were held—to be a nation of gentlemen. They appear to be as courteous amongst themselves as they certainly were to us. One could notice the most polite meetings and partings of Japanese who did not know they were being observed. The school children that one met—and they were everywhere to be seen—were friendly and orderly amongst themselves, and prettily responsive to greetings from us. I heard of no unpleasant incident, but I myself had many examples of courtesy which would be exceptional in some other parts of the world. Not once or twice, but many times, have I asked my way to a place from a person who understood what I wanted but whose answer I was unable to comprehend. On every such occasion he would answer, "I will show you," and would go perhaps half a mile out of his way to do so. Or if a *rikisha* or motor-car was available he would call it and give directions to the man. Courtesy seems to be a natural and very pleasant trait in Japanese character.

SCIENTIFIC ASPECTS OF THE MEETING.—If the Congress left anything at all to be desired it was more time for the reading and discussion of papers. In all, some four hundred papers were sent in, which had to be got through in ten days. This necessitated very strict time limits being imposed upon authors and speakers, and it was a very exceptional paper that could be given more than ten minutes. Though no doubt it would be well to have more time, yet such restriction is not so bad as it might seem. Fairly complete abstracts were available, and were often read in place of the paper. These abstracts were printed and distributed on the morning or afternoon that any particular paper came on, and it could thus be seen in advance what the paper was about, and as all the delegates were staying at the same hotel in Tokyo, there were many other opportunities for discussion. It was in the hotel that some of the most valuable discussions took place, between perhaps the author of a paper and others who were interested. It is often the case in scientific meetings such as this, that informal discussions arising out of papers read are more productive of good than the actual hearing of the papers. To appreciate fully the work described by an author in a written paper, it is necessary to read and study the paper, and in physical and mathematical papers it is frequently important to work out anew the author's mathematical reasoning. For this the publication of the paper is essential, and in the present case most, if not all, of the papers read will in due course be published. Thus although the number of papers offered was very large for the time available, yet I think all the delegates felt that this did not militate against the success of the meeting to the extent which it might have been expected to have done by those who were not present. In future meetings it may perhaps be well if a previous censorship of papers is instituted, so that only those of outstanding importance shall be read.

CONSTITUTION OF THE CONGRESS.—Until the present meeting, I believe the meetings of the congress have been conducted without any very definite constitution or by-laws, much being left to the president, and to the discretion of those organising the next forthcoming meeting—that is to say, to the local organising committee at the place of meeting. At the Tokyo meeting, however, a definite constitution and by-laws were drawn up and received the approval of the conference as a whole. By this constitution the name of the conference is now "The Pacific Science Association," and its meetings are to be held at intervals of not less than two or more than five years. The constitution consists of fifteen clauses, of which Clause 4, relating to the constitution of the Council, is probably the most interesting and important from the point of view of the New Zealand Institute. The administrative work of the association is arranged to be carried on by a council of not more than fifteen members, the seats being allotted to 'Countries' of which eleven or twelve are named in the constitution, leaving three or four vacancies for countries that may at some future time desire to come in. The countries so far named are the United States of America, Canada, Australia, France, Great Britain, Hawaii, Japan, Netherlands, Netherlands East Indies, New Zealand, Philippine Islands, and Russia, and these countries are to be represented on the council each by one member, who is to be elected by its National Research Council, or by some other scientific organisation of recognised standing. The scientific bodies thus having electoral powers are named in the constitution, and in the absence at present of a National Research Council, the New Zealand Institute has been named for New Zealand.

Amongst the by-laws, which consist of fourteen articles, there is one (Art. 7) for which perhaps we may be grateful. It provides that the usual language of the congress shall be English.

Visits to Scientific Institutions.—This journey to Japan presented exceptional opportunities for visiting and obtaining information about the activities of any particular scientific institution there in the work of which one might be interested. In most cases visits of a large body of delegates to these institutions was a part of the programme of the Congress, but at such visits the greatness of the numbers present prevented many questions being asked, or much individual attention being given to any particular visitor. They were, however, most valuable, as they showed all who took part in them how much Japan is doing in the cause of science. One had, moreover, only to express a wish to see any particular institution and a more or less private inspection of it was most willingly and most courteously arranged. In this more complete way I was enabled to see some most interesting organisations, the work of some of which will now be referred to.

Aeronautical Research Institute, Tokyo.—This institute is, and always has been, a part of the Imperial University of Tokyo. The first of the ordinances which govern it states that the Aeronautical Research Institute shall be attached to the Tokyo Imperial University, though its present location is some miles from what is actually the Imperial University building. It concerns itself with the investigation of all subjects relating to aeronautics, a term which it wisely interprets in a very broad manner. It is a development of the Investigation Committee on Aeronautics which was founded under the chairmanship of Dr. A. Tanakadate in 1916. The Research Institute dates from 1918, and, like most other Tokyo institutions, was very seriously damaged by the 1923 earthquake. It is, however, rebuilt sufficiently to enable work to be carried on there pending the completion of a much larger and more complete institution at another part of the city. Much might be said about this institution, but here only a few of the points which were most interesting to myself can be referred to. The work of the institute is divided into twelve departments, which are as follows: Physics, chemistry, metallurgy, materials, wind tunnel, aero engines, aircraft, instruments, aeronautical psychology, central library, workshop, and office.

It will be seen that at the head of this list of departments, which is taken as it stands out of a report of the Institute, the fundamental sciences of physics and chemistry are recognised as of the first importance to progress. This is the case in all the Japanese research establishments of this nature, and there are very many of them. Without progress in the fundamental sciences, progress in the applications is impossible. The whole institution is under the general control of Baron Shiba. The liberal staffing of the various departments is worthy of more than passing notice. Thus the physical department has five chief investigators, nine senior assistants, seven junior assistants, and two laboratory attendants. The chemical department has seven chief members, one senior assistant, five junior assistants, and one laboratory attendant. The aero-engine department has eight chief investigators, twelve senior assistants, fifteen junior assistants, and twenty-two laboratory attendants, and so on throughout the whole of the Institute. The subjects under investigation at present are some nineteen in number in the physical department, nine in chemistry, five in metallurgy, two in materials, seven in the wind-tunnel department, thirty-three in the aero-engine department, eleven in the aircraft department, five in the instrument department, and seven in the aeronautical psychology department, making in all about a hundred different subjects which are under investigation in this one Institute of Aeronautical Research alone. Many researches have been completed and have led to results of great value, and one finds amongst these such subjects as the transverse vibrations of elliptic and rectangular plates, the content of helium and other constituents in the natural gases occurring in Japan, and many others. The bearing of the first of the subjects mentioned is of course in connexion with the vibrations of aeroplane wings, and that of the second with the inflation of dirigible balloons. One must visit Japan to realise what is being done in institutions like this; institutions, that is to say, the whole object of which is research.

It is here and at similar places that every advance in scientific method is examined, and if possible some application of it is made to the practical problems under consideration. The remotely, or seemingly remotely, connected subject of piezo electricity finds a most valuable use in the investigation of the pressure of piston rings and the wearing of cylinder walls. Electric valves find an application here to the examination of the rate of dissemination of the gaseous charge to different parts of the cylinder, and it may be that some alteration in the design of the form of the cylinder from the old cylindrical shape to some other in which the charge is spread more quickly and more uniformly throughout it may result from this work. Very much more could be said about this interesting establishment at which, owing to the courtesy of Baron Shiba, I was able to spend an all too short morning, but it is, after all, only one of many other similar places, and I must refer to some of the others.

The Institute of Physical and Chemical Research.—Perhaps the best way to begin my remarks upon this will be to quote from a pamphlet which was published this year concerning it: "The Institute conducts investigations in the pure sciences of physics and chemistry, aiming at their industrial development, and at the same time engaging in applied research. No undertaking, whether it be in industry or agriculture, would be able to attain sound development unless it was based on physics and chemistry. Particularly in such a densely populated country as Japan, where industrial materials as well as other commodities are not ample, it is essential to aim at the development of industry by having recourse to science, thereby promoting national interests. The object of the institute is to perform this important mission.

"When any physico-chemical applied research is completed in the laboratory it is tested for its industrial applicability, and in case the test shows an appropriate result, arrangement for manufacture is carried out at the Institute; or the manufacture may be entrusted to others; or a new company may be established on the basis of a remunerative contract with the Institute, depending upon the nature of the work. At present there are several undertakings that have already existed as industries or are going to exist as such. As the fundamental cause of success in these applied researches lies in there being sound scientific investigations at the back of them, a part of any profit accruing to the Institute is allotted to the investigation expense of pure science and a further part is given as a reward to the inventor or discoverer."

The staff of this institute numbers 384, of whom 216 are directly engaged in the investigations; the number of distinct lines of research pursued is, this year, 171, whilst last year it was 154. The results of the researches are published, very often in the English language, but they do not appear, as a rule, in any of the more generally recognised scientific journals which we see, at any rate in New Zealand.

Glancing through a list of the investigations, one would scarcely realise that this Institute of Physical and Chemical Research is, like the Aeronautical Research Institute, utilitarian in its work. But the Japanese have realised that for the industries to attain a sound development it is an absolute essential that they should be based upon the fundamental sciences of physics and chemistry, and that any advance in these means a hundredfold corresponding advance in the industries and in agriculture. They therefore interpret the charter in the broadest possible spirit, and amongst the 171 distinct investigations in progress in the Institute there are to be found those relating (*a*) to the transmutation of mercury into gold; (*b*) the calculation of mutual and self inductance; (*c*) photo elasticity; (*d*) the manufacture of synthetic *sake*; (*e*) the by-products derivable from waste human hair, and 166 others. The greatest freedom is given to the investigators in their work; they are free to undertake or reject any proposed problem. They are experts in their work, and are treated as such, but they receive some benefit of a financial kind for any practical applications of their work. I had the benefit of spending an afternoon at this most interesting institution, and was most kindly shown round by Prof. Nagaoka, whose scientific reputation is very well known, and by Viscount Okochi, who is the superintendent and director of it.

The time available was of course much too short to appreciate all or nearly all that was going on, and very little of the work could really be seen; but what I did see showed how complete and efficient the methods of investigation were, and what a valuable stream of knowledge is issuing from it.

The Institute was founded only nine years ago and its income is derived from an endowment of more than £600,000, about one-sixth of which was an Imperial gift, a third was a government subsidy, and the other half consisted of contributions from official sources as well as from individuals. The income is now no doubt being augmented by its interest in the rights of some 140 patents which have been obtained as the result of investigations carried out at the establishment.

The Research Institute for Iron, Steel, and other Metals at Sendai.—It is a remarkable thing, and one to be noticed, that many of the 'practical' research institutions of Japan are connected with universities. The Iron and Steel Institute is a part of the Imperial University at Sendai, and the Aeronautical Institute is part of the Imperial University of Tokyo, whilst the Institute of Physical and Chemical Research is closely connected with the Imperial University at Tohoku. This fact becomes more and more impressive the more of these institutions one is able to obtain information about. The Iron and Steel Institute began in a somewhat small way in 1915 to deal with problems arising out of the War, but its scope has been rapidly enlarged, until in 1924 its staff was seemingly about 54 persons, namely, 22 experts and 32 assistants, with Prof. Honda, a man whose reputation has been recognised in Europe for many years, at their head. The research staff consists of twenty members, all of them men of distinction and learning.

Forty-one problems have been the subjects of investigation since September of last year, of which a few may be enumerated, though these are picked at random from the list: (*a*) The viscosity of molten metals and alloys; (*b*) comparative investigation of hardness testers; (*c*) investigation of magnetic sands; (*d*) the effect of sulphur on iron and steel. The Institute publishes its results—or at least some of them—in the *Science Reports* of the Tohoku Imperial University, in European languages, and has thus published in some accessible European language no less than 140 papers. The knowledge contained in these papers must be a very mine of information for those engaged in metallurgical questions, and it speaks most eloquently for the broadness of the view that the Japanese adopt, that they have published these papers in a European language, as indeed they do most of their papers in every institution. In the vast majority of cases the language used in recent years is English.

The regulations with regard to patent rights arising from work done in the Institute are well worthy of study, especially as similar questions will crop up in connexion with the Department of Industrial Research which is about to be established in New Zealand.

The Geophysical Laboratory at Beppu.—This laboratory, which is a part of the Imperial University of Kyoto—though it is several hundred miles from it—has only been established recently. So far, no publications have issued from it, though a good deal of work is in hand. The laboratory is situated in one of the principal hot-spring regions of Japan. The work undertaken there consists of researches into changes of level, temperature, hydrogen and chlorine ion content, and electrical conductivity of the hot-spring waters. Micro-seismographs magnifying fifty thousand times are to be seen there, and the institution is undoubtedly being established at Beppu on a very broad and valuable basis. Indeed, it might form a better model upon which to establish our own proposed vulcanological station than the Hawaiian Vulcanological Observatory. The latter is, perhaps, more concerned with activities of a living volcano, whereas this Geophysical Laboratory is in a region not very unlike Rotorua, although perhaps of rather less activity than Rotorua. Dr. Shida, of the Geophysical Department of the Kyoto University, is in charge of the laboratory, and many of the instruments in use in it are of his own design.

Research in Japan.—What I have said refers to the institutions that I was able—in the exceedingly short time available—to visit. I am afraid it gives a most imperfect idea of the work that is going on in them, and it certainly gives no idea of the amount of research in progress in Japan. Besides the work at institutions solely intended for research purposes—and to deal at all with these would need a volume rather than a short report—besides these an immense amount of first-class research work is done at the universities themselves. There are forty-five government or municipal research institutions in Japan. As well as these, there are twenty-five other institutions either privately endowed or maintained by business firms (one of these is the Institute of Physical and Chemical Research already referred to), and this number does not include observatories, of which there are many. The average number of research 'experts' employed in these institutions is about twenty, which number does not include those who are classed as 'assistants' and are very much more numerous, probably at least double as many.

The Imperial Universities.—There are six of these, namely, Tokyo, Kyoto, Tohoku (at Sendai), Kyushu at Fukuoka, Hokkaido, and Keijo. There are also other universities, known as private universities. The staffing of these universities is to a New Zealander exceedingly liberal, but it accounts for much that it would be otherwise impossible to explain. The Tokyo University, besides teaching its students, or rather perhaps as an aid to teaching its students, maintains the following institutions: (*a*) The Tokyo Astronomical Observatory; (*b*) the Earthquake Research Institute; (*c*) the Aeronautical Research Institute; (*d*) the Institute for Infectious Diseases; (*e*) the Seismological Institute; (*f*) the Botanic Garden; (*g*) the Marine Biological Station; as well (evidently) as some others.

The Kyoto University has associated with it: (*a*) The Astronomical Observatory; (*b*) the Kamigamo Seismological Station; (*c*) the Beppu Geophysical Laboratory; (*d*) the Seto Marine Station; and (*e*) the Otsu Hydro-Biological Station. These are, of course, in addition to the usual laboratories which are to be found in every modern university.

The general policy and mode of working of these universities can perhaps be seen from considering one department in one of them, and the one I naturally choose is that of physics at Kyoto. The Department of Physics is divided into three sub-departments, namely, (*a*) physics; (*b*) cosmical physics; and (*c*) geophysics. The sub-branch physics has in it four professors, three assistant professors, and two lecturers, and I was informed that there are less than 60 students taking the subject. The sub-branch cosmical physics has two professors and two lecturers. The sub-branch geophysics has three professors, two assistant professors, and nine lecturers. The liberal scale of staffing is thus apparent, and amounts in the sub-branch physics to less than seven students per teacher. The students enter the University at the average age of about twenty-two years. Such a system produces first-class men, and, moreover, so restricts the field of study of the professor or teacher that he is enabled to be really an expert in his branch, rather than a man who perhaps knows something of many branches and knows none of them well.

The cost is of course proportionally high, but that Japan finds that it pays is shown by the figures relating to the Kyoto University, which are taken from the Kyoto University Calendar for 1926. The University is a very modern institution, only boasting twenty-nine years of existence—it was founded in 1897. The cost of it during that year was approximately £5400, whereas during the year 1926 it was £500,000. As there are something a little under 4000 students at the University (in all grades), this cost is about £125 per student per annum at present. In the whole Department of Science in the University of Kyoto there are 85 teachers. To cover the same work in Canterbury College we have about ten teachers. The number of students in this Department in Kyoto is 250, which is probably about what it is in Canterbury College—indeed, it may be more at the latter place.

The same kind of thing holds in every department of all the six Imperial universities of Japan. Japan has realised that the thorough education—specialist education, of course, in every case—of a comparatively few is more the function of the university, and pays the nation better than the cheap sort of education of a great many. Perhaps I may quote from an Imperial ordinance governing universities which was promulgated in 1918. Art. 1 of that ordinance gives a concise statement of the functions of a university as conceived in Japan. It reads: "Universities shall have for their objects the teaching of such sciences, theoretical and practical, as are required for the purposes of the State, and the prosecution of original research in the said sciences; and consideration shall be given to refinement of character with an eye to fostering national ideas." A narrow view of the word "sciences" as used above is not taken, and Art. 2 specifies the departments which may be set up, of which "Literature" is one.

It is no doubt in the spirit of this ordinance that the universities of Japan are such centres of research. They have realised, as some one once put it, that "the function of a university is not to teach," but that it also has the further function of learning as well, and that by learning, teaching is best done. These universities have therefore established such places as the Aeronautical Research Institute and the Beppu Geophysical Laboratory, to which reference has already been made, as well as many other institutions of an analogous sort, and it is to these that the students are drafted as they become more proficient in their work, and they see the work done there as it is done in actual practice, and they advance knowledge at the same time.

In conclusion, I may perhaps refer to an opinion which was expressed to me by one of the Overseas delegates having special knowledge of the interaction of science and industry. He told me that he thought that the organisation of the co-operation of the two is more complete in Japan than in any other of the many countries he has visited (which included England, France, the United States, Czechoslovakia, and Germany), with the exception of one of them, which, so far as I remember, is Germany. Thus the work started in the 'seventies by Ewing and Ayrton and Perry has borne rich fruit for this progressive Empire.

The Diffusion of Culture.

The Frazer Lecture was delivered at Cambridge by Dr. R. R. Marett, reader in social anthropology in the University of Oxford, on Mar. 2. Dr. Marett, taking "The Diffusion of Culture" as his subject, dealt chiefly with the views of Prof. Elliot Smith, whether as expressed positively or as implied in the criticism of rival doctrines. Thus as a critic he stigmatised Tylor's animism as mere guess-work which defies the known facts. Again, he regards "The Golden Bough," however learned, as based on a fallacy and as amounting to nonsense because it does not follow the historical method. The reply to these criticisms seems to be that the whole virtue of scientific method consists in being "sufficient unto the day." To require that what may be proved now might just as well have been proved fifty years ago is to ignore the historical conditions that determine movement of thought. In view of the immense stimulus given to research, no less in the field than in the study, by the working hypotheses carefully formulated as such by Tylor and Frazer, it is absurd to accuse them of having laboured in vain. In short, the critic seems to be deficient in that historic sense which he desiderates in others.

Turning from the polemics to the positive tenets of the diffusionist school, Dr. Marett distinguished between the special question of whether Egypt could be shown to be the sole originator of civilisation and the general question whether a diffusionist method is capable of taking entire charge of cultural anthropology. The evidence for and against the claims of Egypt as the cradle-land of civilisation being too vast to consider briefly, Dr. Marett was content to examine a single specimen of the proofs on which Prof. Elliot Smith relies, namely, his contention that the earliest conception of a deity arose out of certain beliefs connecting the cowry shell with the female principle. Here 'earliest' can scarcely mean more than 'earliest known,' in view of the notorious imperfection of the historical record. Even so, it is possible to cite from palæolithic Europe only, a variety of practices of seemingly ceremonial intention suggesting that the idea of deity may have had many other sources than the one alleged. What Prof. Elliot Smith puts forward with assurance is thus at best a more or less plausible hypothesis which needs to be framed with all due reservations and precautions.

As to the all-sufficing efficacy of the diffusionist method, there is uncertainty at this point within the diffusionist school itself, seeing that Dr. Rivers was for assigning the last word in cultural anthropology to psychology, though only after the study of cultural diffusion had been more fully developed. But surely there is a present need of psychological analysis as applied to primitive culture as we meet with it under existing conditions. Diffusionism offers us merely an exterior history of culture, a number of particular events following one on the other without apparent rhyme or reason. Psychology alone can supply the general law or tendency that brings the particular facts into relation. It alone, therefore, can furnish the hypothetical bridge that leads to the discovery of fresh particulars of the same kind by enabling their real character to be recognised. Prof. Elliot Smith can be shown constantly to assume psychological principles in his account of the diffusion of culture; but since he is unconscious of so doing, his psychology is uncritical and, therefore, crude.

Stated temperately and with a due sense of the difficulties, Dr. Marett is of opinion that Prof. Elliot Smith's theory of Egyptian influence deserves the most careful attention, but the present dogmatic assertions of the diffusionist school are out of place.

University and Educational Intelligence.

CAMBRIDGE.—Prof. J. A. Fleming, Prof. G. F. Stout, and Prof. A. E. H. Love have been elected honorary fellows of St. John's College.

Mr. A. Amos, Downing College, has been reappointed director of the University farm for five years. Various fresh lectureships in mathematics, agriculture, physics, engineering, and economics will be established. Some of these represent steps in completion of the changes from the old conditions to the present ones under the new Statutes.

The report of the Faculty Board of Archæology and Anthropology mentions considerable additions of interest to the collections in the Museum of Ethnology. These include a number of objects of the dolmen age from Portugal and Brittany, presented by Mr. L. C. G. Clarke, English pygmy implements from the Pennine region presented by Mr. F. Buckley, Baron von Hügel's Tongan collection, a magnificent Hindu Indian totem-pole, 45 feet high, and a Kwakintl Indian house-pole in the form of a grizzly bear, presented by Dr. Glaisher, and various bequests already mentioned in these columns.

LONDON.—The title of reader in geometry in the University has been conferred on Mr. J. L. S. Hatton in respect of the post he holds at East London College. Mr. Hatton studied at Hertford College, Oxford, and for two years was demonstrator at the Clarendon Laboratory, Oxford. Since 1896 he has been Principal of East London College and head of the Mathematical Department.

PROF. D. A. GILCHRIST, professor of agriculture at Armstrong College (University of Durham), Newcastle-on-Tyne, and Director of the Northumberland Agricultural Experiment Station at Cockle Park, having reached the age-limit, has resigned. Prof. Gilchrist is best known for his Cockle Park experiments on the use of phosphatic manures and wild white clover for grassland.

THE annual general meeting of the Association of Technical Institutions was held in the Goldsmiths' Hall, London, on Feb. 25-26. The incoming president, Lord Riddell, chose as the subject for a racy address "The Business Climate." He believed that the causes of good and bad trade are just as capable of scientific discovery as are the causes of climatic change; and, in the case of trade, he regarded education and organisation as the means of coming nearer to a state of affairs less charged with uncertainty and error. An important section of the Association's annual report showed that in most institutions there is available a very limited number of books of a technical nature, and, in some cases, what there are appear to be out of date and of no real value. Some six schools reported a provision of £200 per annum for additions and renewals, but in the great majority of institutions the average expenditure is £20-£30 per annum. In order to direct attention to such serious defects in the distribution of technical literature an analysis of questionnaire results was sent to the Association of Special Libraries and Information Bureaux which promoted the reading of a paper dealing with the matter at a recent meeting at Oxford. "The Technical Training of Students for the Worsted and Woollen Industry" (by Prof. E. Midgley); "The Value and Functions of Advisory Committees in Technical Education" (by Mr. G. F. O'Riordan); "The Technical Training of Students for the Cotton Trade" (by Mr. W. Wilkinson): these titles of some of the papers read during the conference will indicate the subjects round which valuable discussion centred. A paper by Mr. J. R. Riddell described excellent work in connexion with training for the printing industry, but was somewhat marred by a singularly imperfect conception of the complementary nature of the contributions to be made to education by industrialists and "well-intending but theoretical educationalists."

IN view of the growing importance of technical education, a paper by Principal J. F. S. Ross, read at the recent meeting of the Association of Technical Institutions, was especially valuable. Dealing with "Some Problems of the Smaller (Technical) Institution," he directed attention to the problem of an institution which has to be staffed by visiting teachers. The method certainly has the advantage of securing specialists who, during the day, are engaged in the trade or profession for which, in the evening, they prepare their students. There are, however, many disadvantages: efficiency and the corporate life of the school are handicapped not because the visiting teacher lacks quality, but because his work is restricted and limited by the essential conditions of his appointment. As part of the solution of the difficulty, Mr. Ross considered that every department of a technical institution which promotes a full-time senior grouped course covering three years should have at least one full-time teacher. The chief obstacle to such an arrangement lies in the present superannuation regulations; but Mr. Ross's paper showed clearly not only the equity of an alteration of these regulations, but also the enhancement of the value of technical education which would result.

Calendar of Discovery and Invention.

March 13, 1759.—In 1757, Clairaut began his long calculations on Halley's Comet, in which he was afterwards assisted by Lalande. In Nov. 1758 he announced that the comet would reach perihelion on Apr. 13, 1759, though its arrival might differ from this date by so much as a month. The comet reached perihelion on Mar. 13, 1759, the accuracy of Clairaut's prediction being regarded as a brilliant triumph of Newton's theory.

March 13, 1781.—Herschel's great review of the heavens began in 1775 and was carried out mainly with telescopes constructed by himself. On Mar. 13, 1781, while examining some small stars, he discovered what he thought was a comet. Further observations and calculations by himself and others, however, proved the newly discovered body to be a planet to which the name Uranus was given by Bode.

March 14, 1794.—Cotton has been cultivated from the dawn of history. It is mentioned in the Rig Veda hymn, composed fifteen centuries before the Christian era, and the roller gin for cleaning cotton was evolved in India 300 B.C. Roller gins, however, are not suitable for cleaning the 'upland' cotton grown in America, where all cotton was cleaned by hand until the invention of Whitney's gin, patented on Mar. 14, 1794. In 1791, 189,500 pounds of cotton had been exported from the United States; nine years after Whitney's invention the amount exported had grown to 41,000,000 pounds.

March 15, 1816.—The national standard of length in Great Britain up to 1824 was the yard of Elizabeth, kept at the Exchequer, which, said Baily, was such that "a common kitchen poker filed at the ends by the most bungling workman would make as good a standard." Through a resolution of the House of Commons on Mar. 15, 1816, the Royal Society initiated experiments to find the length of a pendulum swinging seconds, one of the objects being to compare British and French standards, and these were the beginning of experiments spread over many years which gave us our present standards.

March 17, 1876.—Kelvin, writing to Andrews of Belfast on Mar. 17, 1876, said: "I have to-day been seeing an exquisite electrical experiment, quite a first-class discovery by Dr. John Kerr." What the discovery was Kerr explained to the British Association that year when he showed that when polarised light is reflected from the end of the core of an electro-magnet, the plane of polarisation is rotated under the influence of the magnet in a direction opposite to the conventional direction of the current. These experiments led to the fundamental researches on electro-optics and magneto-optics of later physicists.

March 18, 1700.—The inauguration of an Academy of Sciences at Berlin, after the plan of the Royal Society of London, was decided upon on Mar. 18, 1700. On July 11 the King, Frederick I., signed the letters patent which made it a State institution and Liebnitz was proclaimed president for life. The King, it is said, gave his consent to please his wife. In 1744 the Academy was re-organised by Frederick the Great, who attracted Euler, Lagrange, and other eminent foreigners to Berlin.

March 19, 1702.—In the *Post Man* of this date appeared an advertisement to the effect that Captain Savery's engine, which raises water by the "force of fire with less expense than any other forces of horses or hands" could be seen at his "Workhouse in Salisbury Court, London, against the old Playhouse." This 'Workhouse,' the first steam-engine factory in the world, was close to St. Bride's Church, Fleet Street.

E. C. S.

Societies and Academies.

London

Royal Society, Mar. 3.—**W. L. Bragg** and **J. West**: The structure of certain silicates. Each series of silicates classified together as a mineral species, although with wide variation in chemical composition, is regarded as based on a characteristic type of oxygen assemblage. A number of structures are based on cubic or hexagonal arrangements of closest packing of oxygen atoms, the metal and silicon atoms being inserted into this framework. The dimensions of the unit cell are related to the fundamental spacings of this simple background of oxygen atoms, on which the complex pattern formed by the other atoms is embroidered. Closest-packing is found for an extended series of compounds, ranging from BeO, Al_2O_3, $BeAl_2O_4$, and $MgAl_2O_4$ to cyanite Al_2SiO_5, olivine $(Mg, Fe)_2SiO_4$, monticellite $MgCaSiO_4$, and the chondrodite $[(MgOH)_2Mg_3(SiO_4)_2]$ group. The arrangement of oxygen atoms is in general more complex, closest-packing being an exceptionally simple case, but the packing of oxygen atoms seems to remain the predominant feature of the structure.

M. C. Johnson: Doppler effects and intensities of lines in the molecular spectrum of hydrogen positive rays. The luminosity of hydrogen positive rays was examined with apparatus capable of maintaining constant electrical and gas conditions over very long exposures. About 150 lines present in the positive ray spectrum are listed, and also about 100 strong lines conspicuous by their absence. Five lines with Doppler components not before recorded are found, including one displacement to the red. From measurement of the Doppler components in both atomic and molecular spectra, evidence as to the carriers of both is found. Certain lines are carried by H_2, and only one is probably carried by H_3. The displaced Balmer lines are due to free atoms, not to those newly dissociated. The Fulcher characteristics of the secondary spectrum weaken towards the violet, as also does the ratio of displaced to undisplaced intensities in the Balmer lines. The majority of the secondary lines are due either to radiation or to the impact of positive ions on stationary molecules which have not been recently ionised.

E. Mallett: A vector loci method of treating coupled circuits. If in the first of two coupled circuits an E.M.F. of constant amplitude and variable frequency is introduced, the currents in the primary and secondary respectively may be written $i_1 = e/Z'$ and $i_2 = e/Z''$, where Z' and Z'' are complex impedance operators. The loci of these impedances, as ω is varied, have definite geometrical forms; Z'' is a parabola, Z' a cissoid. Current loci are inverse of impedance loci. When the circuit condensers are varied instead of ω, the loci degenerate into straight lines and circles.

H. S. Allen and **I. Sandeman**: Bands in the secondary spectrum of hydrogen. A band in the secondary spectrum of hydrogen at higher pressures, recently described, comprising a P, Q, and R combination, was attributed to triatomic hydrogen. It has since been found to be one of a considerable system of bands which occur in groups, the bands of a group being spaced out at intervals of very nearly 92 wave-numbers, the spacing being in some cases approximately constant and in others conforming to a quadratic law. In some cases the lines of the groups are enhanced in the spectrum of the arc in hydrogen at higher pressures. The bands must originate in molecules with large moments of inertia, probably active or triatomic hydrogen.

C. G. Darwin and **W. H. Watson**: The constants of the magnetic dispersion of light. A review of various dispersion formulæ for the magnetic rotation of light shows the great practical advantage of Becquerel's, which determines an effective *e/m* from a comparison of the rotation with the refractive index. This formula is applied to all transparent substances for which the rotation has been measured: it is shown that no other theoretically possible terms are needed to represent the rotation. For hydrogen gas the ratio is unity, for all other observed substances less, ranging for the most part between 40 and 80 per cent. The only exceptional substance is oxygen gas, which completely refuses to fit any reasonably probable formula.

Royal Microscopical Society, Jan. 19.—**James A. Murray**: Nuclear degenerations due to multipolar mitosis (Presidential address). Personal recollections were given of the late Prof. Theodor Boveri, on whose material of disperm echinoderm eggs the investigations were carried out. A number of characteristic nuclear degenerations occur at a later stage of development in echinoderm eggs which have been fertilised by two spermatozoa and in which the first segmentation division is tri- or quadri-polar. The commonest form of degeneration involves a separation of the chromatin and achromatic parts of the nucleus with progressive condensation of the chromatin. Rarer forms of degeneration similar to the formation of chromidia and to the synaptic figures of gematogenesis may be of theoretical importance. Some of the commoner forms of degeneration could be recognised in tumour-like proliferations of lymphoid tissue in the mouse.

Society of Public Analysts, Feb. 2.—**T. Hedley Barry**: Arsenic in printing ink. Most of the printing-ink pigments contain arsenic, and it is possible to classify them into three groups on the basis of the amounts of arsenic present. A limit of 1 part of arsenic in 50,000 of the ink pigment should satisfy the most stringent requirements of health authorities; but this mode of expression is unsatisfactory, and it would be preferable to fix a limit of arsenic per unit area of the printed paper or wrapping.—**G. D. Elsdon** and **J. R. Stubbs**: The immersion refractometer and its value in the analysis of milk. The refraction of a milk serum apparently changes with two factors—the percentage of solids-not-fat, and the acidity of the milk. The decreased refraction due to added water may be entirely masked by the souring of the milk; up to 10 per cent. of added water may be entirely overlooked in this way. The examination of about one thousand mixed milks with a Zeiss immersion refractometer shows that the average refraction for milk serum, when the copper sulphate method is used, is about 38·3 scale divisions in the case of commercially fresh milks. The method offers no advantage over the usual determinations.—**Paul Haas** and **Barbara Russell-Wells**: Irish moss mucilage and a method for its determination. Irish moss, or carrageen mucilage, consists of a mixture of two ethereal sulphates. These can be determined by precipitation with benzidine chloride and titration of the washed precipitate with standard sodium hydroxide solution. Free sulphates, if present, are first precipitated by adding excess of barium chloride. The method can be used in the presence of gelatin, gum arabic, agar-agar, and fruit pectins.

Optical Society, Feb. 10.—**T. Smith**: Some uncultivated optical fields (Presidential address): (1) A graphical method, by which the properties of an optical system over the whole image field may be explored rapidly and with useful accuracy, is developed. The method is recommended for the investigation of 'best form' spectacle lenses, and for the preliminary exploration of new forms of photographic lenses. (2) The use of the characteristic function in the design of optical systems is discussed, and it is shown that it is always possible to construct such functions for optical systems having surfaces of any given shape. The optics of the future is likely to depend essentially on the use of the characteristic function. (3) The balancing of aberrations is also discussed. (4) As a special application of these methods it should be possible to design optical systems by calculations on equivalent lenses which are 'thin' in the usual sense. For the actual construction the equivalent 'narrow' lenses, or lenses which are just thick enough to attain the required aperture and strong enough to withstand treatment in manufacture, would be used. The correlation of the properties of 'thin' and 'narrow' lenses should prove a fruitful field.

Dublin.

Royal Irish Academy, Jan. 24.—**G. H. Carpenter**: Further records of Collembola from Spitsbergen. The paper comprises the results of the collecting and observational work done by members of the Merton College Expedition of 1923 and the Oxford University Arctic Expedition of 1924. The Collembola described were, for the most part, obtained from the far northern coast of the West Island and from the shores and islets of Hinlopen Strait between the West Island and North-east Land; the abundance of several species enduring the severe climate of this district is remarkable. *Isotoma olivacea* Tullb., found above the shore of Green Harbour, Icefjord, is an addition to the recorded Spitsbergen fauna, and a three-spined form of the common *Achorutes longispinus* Tullb. is noteworthy.

Feb. 14.—**A. W. Stelfox**: The Aculeate Hymenoptera of Ireland. The insects are grouped under the four super-families Apoidea, Sphecoidea, Vespoidea (including the Chrysididæ and Bethylidæ) and Formicoidea. A hundred and seventy-one species are definitely recorded as found in Ireland, and notes of their habits are given. Many of the commonest of British aculeates are absent from Ireland.

Paris.

Academy of Sciences, Jan. 31.—**E. Fichot**: The relation between the maximum velocity of the current and the amplitude of the tide.—**Paul Pascal** was elected a Correspondant of the Academy for the section of chemistry.—**Bertrand Gambier**: Surfaces which are not surfaces of revolution and have their geodesics closed.—**Henri Labrouste**: The analysis of the curves resulting from the superposition of sinusoids.—**S. A. Janczewski**: The theorems of oscillation of the regular problems of Sturm for ordinary linear differential equations of the fourth order.—**Walter Saxer**: Quasi-exceptional meromorph functions.—**R. Gosse**: W surfaces and surfaces of constant curvature.—**Beniamino Segre**: The integration of a certain system of differential equations.—**Nikola Obrechkoff**: The singular points of analytical functions.—**Louis de Broglie**: The atomic structure of matter and radiation and undulatory mechanics.—**P. Dupont**: The application of conjugated vortices to the aerodynamics of the circle and its profiles.—**R. Wavre**: The heterogeneous fluid mass in rotation and the internal movements of the planets.—**P. Helbronner**: The measurement of an arc of meridian of 8° amplitude, comprised between the north of the Jura and the south of Sardinia.—**Mlle. M. Hanot**: The enlargement of the Balmer lines by the intermolecular electric field. The widening of the lines is probably due to the Stark effect of the intermolecular field. According to the calculations of Holtsmark, the width of the line should be proportional to $n^{\frac{2}{3}}$, n being the density of the ions. Experimental confirmation of this is given, at least approximately.—A. Gargam de **Moncetz**: The chemical actions of radiations. Remarks on recent communications on this subject by H. Belliot and by P. Villard. Reference is made to results of experiments published by the author in 1908 and 1909.—**L. Meunier** and **G. Rey**: The determination of the isoelectric point of wool and silk. Applications.—**M. Wilmet**: The sensibility of some reagents to gaseous hydrogen sulphide.—**Auguste Lumière** and **Félix Perrin**: A new organo-metallic derivative of gold. A solution of sodium thiopropanolsulphonate is mixed with a concentrated auric chloride solution, when the new salt is precipitated. Its therapeutic application is suggested.—Emile **Saillard**: The coloration of products of the sugar factory.—**Ph. Joyet-Lavergne**: The action of osmic acid and the physico-chemical characters of the sexualisation of the cytoplasm.—Joseph **Devaux**: The existence and localisation of vertical ascending air currents in the neighbourhood of the Pic du Midi: their utilisation by vultures.—G. **Ollivier**: A Ceramium containing *bromuques*.—L. **Mercier** and J. **Villeneuve**: The controlling muscles of the lunule in *Eristalis tenax*. Sexual dimorphism.—P. **Vignon**: The ancestral origins of the dragon fly.—Mlle. S. **Perle**: The origin of the first genital outline in *Bufo vulgaris*.—G. **Athanassopoulos**: Certain migrations of eels in Greece.—S. **Posternak**: The phosphorus-containing nucleus of casein.

Brussels.

Royal Academy of Belgium, July 3.—P. **Bruylants** and A. **Dewael**: Contribution to the study of the action of organo-magnesium compounds on nitriles. Glutaronitrile and magnesium-benzyl-chloride. This reaction differs from that between the same nitrile and magnesium-phenyl-bromide: the product would appear to be a cyclic amidine.—Edm. **van Aubel**: The calculation of the refractive indices of mixtures and the formulæ of Dieterici and Lichtenecker. These two formulæ are applied to published data on mixtures of acetone-water, and sulphuric acid-water, and the Dieterici formula is shown to agree better with the experimental results for these two mixtures.—P. **Fourmarier**: Observations on the age of the sedimentary strata of the Belgian Congo exterior to the Lualaba system.—Th. **De Donder** and Fr. H. **van den Dungen**: The quantification of relativistic systems.—A. **Castille**: The ultra-violet absorption spectra of some substances with two benzene nuclei.—G. **Van Lerberghe**: The velocity of physico-chemical transformations.—Lucien **Godeaux**: A double plane of genus zero and bigenus one.—L. **Vuylsteke**: Contribution to the study of the reaction between organo-magnesium compounds and nitriles. Dimethylcyanamide.—Désiré **Tits**: The action of amino-acids on the germination of *Phycomyces nitens*.

Aug. 7.—Edm. **van Aubel**: The thermoelectric power of alloys. Experimental study of bismuth-thallium, antimony-tin, and antimony-silver alloys, from the point of view of the variation of the thermo-electromotive force with the percentage composition of the alloy. The curve of the bismuth-thallium alloys shows one definite compound, Bi_2Tl_3. The antimony-tin curve shows two discontinuities, corresponding to definite compounds Sb_2Sn_3 and $SbSn$, and Ag_3Sb is shown on the antimony-silver curves.—J. E. **Verschaffelt**: The variation of surface tension with temperature. The theoretical conclusions deduced by Van der Waals on the variations of the surface tension with temperature in the neighbourhood of the critical temperature are not in agreement with experiment. Van der Waals has assumed a perfect continuity of the equation of state in the neighbourhood of the critical point, and as this assumption is regarded as not legitimate, an alternative proof not assuming this continuity is given. The resulting equation is in fair agreement with experimental results.—Victor and Laure **Willem**: The influence of the respiratory movements on the cardiac pulsation in teleostean fishes.—R. **Moens** and H. **Steffens**: The thermionic phenomena in a magnetic field. The action of the magnetic field is shown by experiment to diminish the plate current and retard saturation.—G. **Homès**: Various energy balances of the Maxwell field plunged in a Minkowski field.—G. **Balasse** and O. **Goche**: The luminescence spectrum of cæsium produced in the discharge without electrodes.—A. **Piccard** and E. **Stahel**: The realisation of the Michelson experiment in a free balloon. The experimental error was of the same order as the positive results obtained, so that no definite conclusion can be drawn.

Rome.

Royal Academy of the Lincei, Dec. 19.—E. **Paternò**: The transmutation of the elements.—S. **Baglioni**, L. **Bracaloni**, and A. **Galamini**: Investigations on the physiological action of alcohol: the alcohol content of the blood of a fasting man following ingestion of alcoholic liquors. The curve showing the relation between the proportion of alcohol in the blood and the tissue since the alcoholic drink was taken varies greatly in form according as the subject of the experiment is or is not a habitual drinker. With the latter the maximum amount of alcohol in the blood is always reached, and this alcohol is dispersed, more rapidly than is the case with an abstainer. The subjective phenomena (drowsiness, incipient drunkenness, etc.) are related directly to the concentration of the alcohol in circulation in any one individual, and inversely to the rapidity with which, in different individuals, the alcohol disappears from the blood.—E. **Bortolotti**: Conform representations, and a new physical interpretation of Levi-Civita's parallelism.—L. **Fantappiè**: The theory of analytical functions in the integration of linear equations with partial derivatives of any order.—A. **Weinstein**: The analytical representation of certain aperiodic movements.—G. **Rossi**: The scintillation of the stars. A historical résumé is given as a preface to a description of experimental work.—A. **Carrelli**: The paramagnetism of the elements between calcium and zinc. As with the rare elements, so also with the elements constituting the group between calcium and zinc, spectroscopic data indicate a double period of variation in the number of magnetons as a function of the atomic number.—G. **Scagliarini**: Additive compounds of salts of quadri- and bi-valent elements with organic bases: probable nature of the secondary valencies.—F. **De Carli**: Reactivity of manganese dioxide in the solid state. Mixtures of manganese dioxide with the alkaline earths undergo exothermic reactions, which begin at comparatively low temperatures, namely, 150-250°; the mixture with cuprous oxide commences at 380° and that with stannous oxide at 180°. The oxidation of the dioxide is influenced by lead peroxide and by various anhydridic metallic oxides.—M. **Salfi**: Biology of *Clavelina lepadiformis* (Müller).—E. **Remotti**: Phenomena accompanying the crisis of sexual maturation of Gambusia. As regards oxidation processes, sexually immature forms of Gambusia exhibit uniform behaviour, interrupted only by the advent of sexual maturation, which acts differently in the two sexes.

Foreign.

Publications of the National Academy of Sciences of the United States of America (1915–1926). Part i: Index to the First Ten Volumes of the Proceedings (1915–1924); Part ii: List of other Publications of the Academy from 1863–1926; Part iii: List of Publications of the National Research Council from 1916–1925. (Vol. 13, No. 1, Part 2, January 1927, Proceedings of the National Academy of Sciences.) Pp. 197. (Washington, D.C.) 1.50 dollars.

Carnegie Institution of Washington. Year Book No. 25, July 1, 1925, to June 30, 1926; with Administrative Reports through December 10, 1926. Pp. xix+451. (Washington, D.C.: Carnegie Institution.)

Department of Commerce: U.S. Coast and Geodetic Survey. Serial No. 366: Isostatic Condition of the United States as indicated by Groups of Gravity Stations. By William Bowie. Pp. ii+11. (Washington, D.C.: Government Printing Office.) 5 cents.

New Dynamical Wave-Theory of the Tides: Discovery of the Physical Cause of the Variation of Latitude, with Calculation of the Period and Amplitude of the Polar Motion, from the observed Oscillations of the Unsymmetrically situated Ocean Hemisphere, including a revised Cotidal Map of the Oceans, now shown to be Oscillating in Synchronous World-Waves coperiodic with the Disturbing Forces, Laplace's Principle, together with an Investigation of other Laws of the Motion of the Sea hitherto unknown, and an Improved Method for Calculating the Rigidity of the Earth. (H.O. No. 207.) (Published and Sold by the Hydrographic Office under the Authority of the Secretary of the Navy.) Pp. iii+91. (Washington, D.C.: Government Printing Office.) 60 cents.

Report of the Secretary of the Smithsonian Institution for the Year ending June 30, 1926. (Publication 2877.) Pp. vi+185. (Washington, D.C.: Government Printing Office.)

Smithsonian Miscellaneous Collections. Vol. 78, No. 3: The Classification and Distribution of the Pit River Indian Tribes of California. (E. H. Harriman Fund.) By Dr. C. Hart Merriam. (Publication 2874.) Pp. 52+27 plates. (Washington, D.C.: Smithsonian Institution.)

Annual Report of the Director, United States Coast and Geodetic Survey, to the Secretary of Commerce for the Fiscal Year ended June 30, 1926. Pp. iv+60+16 plates. (Washington, D.C.: Government Printing Office.) 25 cents.

Smithsonian Institution: United States National Museum. Contributions from the United States National Herbarium, Vol. 23, Part 5: Trees and Shrubs of Mexico (Bignoniaceae-Asteraceae). By Paul C. Standley. Pp. ii+1313-1721. 50 cents. Bulletin 134: Material Culture of the People of South-eastern Panama, based on Specimens in the United States National Museum. By Herbert W. Krieger. Pp. v+141+37 plates. 40 cents. (Washington, D.C.: Government Printing Office.)

Department of Commerce: Bureau of Fisheries. Document No. 968: Plankton of the Offshore Waters of the Gulf of Maine. By Henry B. Bigelow. Pp. 509+20 plates. (Washington, D.C.: Government Printing Office.)

State of Connecticut. Public Document No. 24. Forty-ninth Report of the Connecticut Agricultural Experiment Station, New Haven, Conn., for the year 1925. Pp. 721+26 plates+23T+xxxv. Public Document No. 47: State Geological and Natural History Survey. Volume 7, Bulletins 33-35, 1923-1925. Pp. 70+8 plates+307+20 plates+17. (Hartford, Conn.: State Library.)

Diary of Societies.

SATURDAY, March 12.

Institution of Municipal and County Engineers (South-Western District) (at Bath), at 12.

Royal Institution of Great Britain, at 3.—Dr. J. B. McEwen: Beethoven (3).

North of England Institute of Mining and Mechanical Engineers (Associates' and Students' Section) (at Newcastle-upon-Tyne), at 3.—The following paper will be read:—W. Britton: Systems of Conveying.—The following papers will be open for further discussion:—Screening and Washing Plant at Deaf Hill Colliery, by L. F. H. Booth; Steam and Electric Locomotives for Colliery Purposes, by P. F. Hope; Winning Thin Seams of Great Britain, by W. Leebetter; Dry Cleaning of Coal, by J. S. Carson.

MONDAY, March 14.

Cambridge Philosophical Society (in Cavendish Laboratory), at 4.30.—Prof. G. I. Taylor: An Experiment on the Stability of Superposed Streams of Fluid.—Dr. C. D. Ellis and W. A. Wooster: The Absolute Intensities of the γ-rays of Radium B and Radium C.—P. M. S. Blackett: The Limits of Classical Scattering.—J. A. Gaunt: The Stopping Powers of Hydrogen Atoms for α Particles according to the New Mechanics.—L. H. Martin: Absorption Coefficients for X-rays.

Royal Society of Edinburgh, at 4.30.—Sir Alfred Ewing: Exhibition of some of his Models illustrating the Molecular Process in Ferromagnetic Induction, which have been prepared for the Historical Collection in the South Kensington Museum.—Prof. J. H. Ashworth: The Distribution of Anopheline Mosquitoes in Scotland.—A. D. Hobson: Study of the Fertilisation Membrane in the Echinoderms.—*To be read by title*:—W. L. Calderwood: Note on the Salmon of the R. Grand Cascapedea, Canada.

Royal Geographical Society (at Lowther Lodge), at 5.—Prof. W. E. Soothill: Chinese Cartography.

Royal College of Surgeons of England, at 5.—Sir Arthur Keith: The Peoples of the East: Past and Present (6): Evidence bearing on the Distribution of Racial Types in Southern and Western Asia in Past Times.

Institution of Automobile Engineers (Birmingham and Wolverhampton Centres) (at Chamber of Commerce, Birmingham), at 7.—A. P. Young and L. Griffiths: The High-Tension Magneto, with especial reference to its Design, Manufacture, and Service.

Institution of Automobile Engineers (Loughborough Graduates' Meeting) (at the College, Loughborough), at 7.—C. Legge: Modern Motor Cycle Engines.

Institution of Electrical Engineers (North-Eastern Centre) (at Armstrong College, Newcastle-upon-Tyne), at 7.—F. H. Clough: The Stability of Large Power Systems.

Institution of Mechanical Engineers (Graduates' Section, London), at 7.—E. F. Cordell: Efficiency of the Repair Shop.

Institute of Metals (Scottish Local Section) (Annual General Meeting) (at 39 Elmbank Crescent, Glasgow), at 7.30.—G. W. Tyrrell: Moulding Sands.

Royal Institute of British Architects, at 8.—H. Robertson: Modern French Architecture.

Royal Society of Arts, at 8.—G. I. Finch: Some Industrial Applications of Electrothermics (Cantor Lectures) (1).

Institution of Electrical Engineers (Western Centre) (at Exeter).—R. B. Mitchell: Home Lighting.

Medical Society of London.—Dr. J. Forestier: Demonstration of Lipiodol Injections.

TUESDAY, March 15.

Royal College of Physicians of London, at 5.—Prof. F. R. Fraser: Cardiac Dyspnœa (Goulstonian Lectures) (2).

Royal Institution of Great Britain, at 5.15.—Dr G. Shearer: X-rays and the Chemical Molecule (1).

Royal Statistical Society (at Royal Society of Arts), at 5.15.—Sir Alfred Watson: National Health Insurance: a Statistical Review.

Royal Society of Medicine, at 5 30.—General Meeting.

Mineralogical Society, at 5.30.—C. E. Tilley: A Melilite-spurrite-Ca_2SiO_4 Assemblage from Larne (Antrim).—G. Greenwood: Rotating Crystal X-ray Photographs.—Dr. G. T. Prior: Alkaline Rocks from Nimrud Volcano, Armenia.

London Natural History Society (at 40 Winchester House, E.C.), at 6 30.—Dr. E. J. Salisbury: Woodland Vegetation.

Royal Photographic Society of Great Britain, at 7.—R. N. Speaight: Home Portraiture in Many Lands.

Institute of British Foundrymen (Lancashire Branch, Burnley Section) (at Municipal College, Burnley), at 7.15.—A. Buck: The Mixing of Cast Iron, with special reference to Carbon, Silicon, Phosphorus, Manganese, and Sulphur.

Royal Society of Medicine (Pathology Section) (Annual General Meeting), at 8.30.

WEDNESDAY, March 16.

Royal Irish Academy, at 4.15.

Royal Society of Medicine (Comparative Medicine Section), at 5.

Royal College of Surgeons of England, at 5.—Dr. H. Carlill: The Simulation of Surgical Affections by Hysteria.

Society of Chemical Industry (Liverpool Section) (Annual Meeting) (at Liverpool University), at 6.—Prof. J. C. Drummond: Bio-chemical Aspects of the Nature of Life.

Institution of Civil Engineers (Students' Meeting), at 6.30.—F. C. Jordan: Fire-Protection in Buildings, with special reference to Reinforced-Concrete Construction and Automatic Sprinklers.

Institution of Electrical Engineers (South Midland Centre) (Wireless Sub-section Meeting) (at University, Birmingham), at 7.—C. Robinson: Characteristics of Audio-frequency Amplifiers used in Telephonic Repeaters.

Institution of Electrical Engineers (Sheffield Sub-Centre) (at Royal Victoria Hotel, Sheffield), at 7.30.—Dr. W. H. Eccles: Address.

Merseyside Aquarium Society, at 7.30.—F. Jefferies: Aquatic Plants.

Royal Meteorological Society, at 7.30.—Prof. G. I. Taylor: Turbulence (G. J. Symons Memorial Lecture).

Royal Society of Arts, at 8.—Dr. R. E. M. Wheeler: History by Excavation.

Entomological Society of London, at 8.—Major R. W. G. Hingston: Protective Devices in Spiders' Snares.

Folk-Lore Society (at University College), at 8.—Exhibits and Short Communications.

Oxford University Junior Scientific Club, at 8.15.—Prof. H. E. Armstrong: The Failure of our Universities and their Future.

Society of Chemical Industry (South Wales Section) (at Swansea Technical College).—E. A. Tyler: Further Notes on Pure Chemicals.

Institute of Chemistry (London Section).

Society of Glass Technology (at Birmingham).

THURSDAY, March 17.

Royal Society, at 4.30.—Prof. W. L. Bragg and J. West: The Structure of Certain Silicates.—W. A. Wooster: The Analysis of Beams of Moving Charged Particles by a Magnetic Field.—J. F. Spencer and E. M. John: The Magnetic Susceptibility of some Binary Alloys.

Royal College of Physicians of London, at 5.—Prof. F. R. Fraser: Cardiac Dyspnœa (Goulstonian Lectures) (3).

Royal Institution of Great Britain, at 5.15.—J. Guild: Colour Measurement and Standardisation (1).

Institution of Mining and Metallurgy (at Geological Society), at 5 30.

Child-Study Society (at Royal Sanitary Institute), at 6.—Dr. J. R. Rees: Completion of the Education of the Parent.

Institution of Electrical Engineers, at 6.—Prof. W. M. Thornton: What is Electricity? (Faraday Lecture).

Royal Aeronautical Society (at Royal Society of Arts), at 6.30.—M. A. Giblett: Line Squalls.

Institute of Metals (London Local Section) (at 83 Pall Mall), at 7.30.—C. H. Barrs: The Works Chemist.

Chemical Society, at 8.—F. G. Mann: Tetrachloro-(triaminopropane γ-monohydrochloride) platinum, a New Type of Optically Active Complex Salt.

C.B.C. Society for Constructive Birth Control and Racial Progress (at Essex Hall, Strand), at 8.—A. S. E. Ackermann: Popular Fallacies connected with Birth Control.

Royal Society of Tropical Medicine and Hygiene (Laboratory Meeting) (at Royal Army Medical College), at 8.15.—Demonstrations by Drs. S. Adler, A. Balfour, Maj. J. S. K. Boyd, Maj. C. R. Chadwick, C. MacHattie, C. A. Hoare, Drs. Saiki, E. C. Smith, H. H. Scott, A. C. Stevenson, C. M. Wenyon, Prof. Warrington Yorke, and Dr. A. R. D. Adams.

Society of Glass Technology (at Birmingham).

FRIDAY, March 18.

Biochemical Society (Annual General Meeting) (at University College), at 4.30.—B. Holmes and E. Holmes: Carbohydrate Metabolism of the Brains of Normal and Diabetic Animals.—P. Eggleton and M. G. Eggleton: Phosphagen.—C. Rimington and H. D. Kay: The Phosphorus of Caseinogen.—Dr. R. K. Cannan and B. C. J. G. Knight: Observations on the Sulphydryl-disulphide System.—L. C. Baker and G. F. Marrian: Estimation of Adrenaline.—L. C. Baker, G. F. Marrian, and Prof. J. C. Drummond: Observations on the Adrenals of Rats with relation to Vitamin B.—S. Kon and Prof. J. C. Drummond: The Relation of Vitamin B Deficiency to Inanition in the Pigeon.—A. Hassan and Prof. J. C. Drummond: The Relation of certain Dietary Factors in Yeast to Growth on Diets rich in Protein.—H. J. Channon and A. C. Chibnall: The Presence of Calcium Salts of Glyceridephosphoric Acids in the Ether Extract of Cabbage Leaf Cytoplasm.—O. Rosenheim: Some Sterol Colour Reactions in their Relation to Vitamin A.—M. H. Roscoe: Some Observations on the Dual Nature of Vitamin B.—R. V. Stanford: (a) A Simple Automatic Apparatus for the Rapid, Quantitative Removal of Ammonia from Solutions; (b) The Pulsating Bubble: A Device for Preventing 'Bumping' in Boiling Liquids.

Royal College of Surgeons of England, at 5.—R. St. Leger Brockman: The Toxæmia of Acute Intestinal Obstruction.

North-East Coast Institution of Engineers and Shipbuilders (at Literary and Philosophical Society, Newcastle-upon-Tyne), at 6.—D. M. Shannon: Development of the Fiat Marine Oil Engine.

Institution of Mechanical Engineers (Informal Meeting), at 7.—F. E. Robinson: Some Aspects of Workshop Organisation.

Royal Photographic Society of Great Britain (Pictorial Group Meeting), at 7.—W. Thomas: Portraiture by Flashlight.

Photomicrographic Society (at 4 Fetter Lane), at 7.—Members' Evening.

Junior Institution of Engineers, at 7.30.—J. Calderwood: An Investigation of Tortional Vibration, with particular reference to Aircraft Engines.

Royal Institution of Great Britain, at 9.—E. Hatschek: Rigidity and other Anomalies in Colloidal Solutions.

Institution of Chemical Engineers (jointly with Coventry Engineering Society, and Society of Chemical Industry, Chemical Engineering Group) (at Coventry).—Prof. J. W. Hinchley: The Importance of Chemistry to the Engineer.

SATURDAY, March 19.

Geologists' Association (in Department of Anatomy, University College), at 2.30.—Prof. G. Elliot Smith: Demonstration of Fossil Remains of Man.

Association of Mining Electrical Engineers (North of England Branch), at 3.—C. D. le Maistre: Standardisation of Colliery Electrical Requisites.

Royal Institution of Great Britain, at 3.—Sir Ernest Rutherford: The Alpha Rays and their Application to Atomic Structure.

Physiological Society (at University College).—Annual General Meeting.

PUBLIC LECTURES.

SATURDAY, March 12.

Horniman Museum (Forest Hill), at 3.30.—Miss M. A. Murray: Trading in Ancient Egypt.

SUNDAY, March 13.

Guildhouse (Eccleston Square), at 3 30.—Major W. Tudor Pole: Universalism in Religion, with special reference to the Bahai Faith.

MONDAY, March 14.

University of Leeds, at 8.—Sir Bernard Pares: Present-Day Russia.

University College, at 8.30.—Sir Oliver Lodge: A Century's Progress in Physics (Centenary Address).

THURSDAY, March 17.

King's College, at 5.30.—Prof. L. T. Hobhouse: The Mind: Sociology.

University College, at 5.30.—Prof. J. Chevalier: Idéalisme et Réalisme. Le Français est-il Idéaliste? Est-il Réaliste?

SATURDAY, March 19.

Horniman Museum (Forest Hill), at 3.30.—H. N. Milligan: Animal Growth and Evolution.

CELEBRATION.

March 18 to 20.

Mathematical Association (Yorkshire Branch) (at Grantham).—The Two-Hundredth Anniversary of the Death of Sir Isaac Newton.

March 18, at 8.—Civic Reception by the Mayor of Grantham at the Guildhall, Grantham.

March 19, at 10 a.m.—Bicentenary Scientific Meeting in the Old School, King's School, Grantham, with addresses by:—
Sir J. J. Thomson: Newton's Work in Physics.
Sir F. Dyson: Newton's Work in Astronomy.
Dr. H. Lamb: Newton's Work in Mechanics.
Prof. G. H. Hardy: Newton's Work in Pure Mathematics.
Dr. J. H. Jeans will preside and give an address on Isaac Newton.
At 2.—Pilgrimage to Woolsthorpe Manor House (Newton's birth-place) and visit to Stoke Rochford, where Mr. C. Turnor will speak on Newton's Countryside.—At 7.30.—Celebration Dinner at the George Hotel, Grantham. Chairman: Sir J. J. Thomson. Speakers: Prof. H. H. Turner, Prof. E. T. Whittaker, the Bishop of Birmingham, and the Bishop of Lincoln.

March 20, at 11.15 a.m.—Bicentenary Service at the Parish Church, Grantham. Preacher—The Bishop of Birmingham.

CONGRESSES.

April 20 to 24.

Journées Médicales Marseillaises et Coloniales (at Marseilles).—Prof. Cantacuzène: The Rôle of the Streptococcus in the Etiology of Scarlet Fever.—Dr. Mayer: Recent Advances in the Treatment of Cancer.—Prof. Ottolenghi: Malaria.—Dr. N. Bernard: Beri-beri.—Prof. Imbert: Bone-grafting.

April 25 to 28.

German Society for Internal Medicine (at Wiesbaden).—Discussions on Psychotherapy, introduced by Gaupp and Fleischmann; Results of Recent Functional Investigations of the Stomach and Duodenum, introduced by G. Katsch.—A joint meeting with the German Röntgen Society will be held on April 26, with a discussion on the Significance of Röntgen-ray Examination of the Lungs and Mediastinum for Internal Medicine (excluding Tuberculosis), introduced by Distlen, Assmann Haenisch and Lorey, and Fleischner.

SATURDAY, MARCH 19, 1927.

Scientific Method in Bibliography.

THE printed chronicle of human endeavour in all civilised countries of the world, in many tongues and recorded in multifarious publications, has long been accumulating at a rate so great, that not merely is its co-ordination beyond the power of any single mind, but also no central institution has been able to analyse it, so that this priceless store of knowledge may be made available for further advance.

At an earlier period, the author of a scientific or technical paper may have cherished the fancy that, by publishing his work, he was giving it to the world. To-day we have learnt by experience that to print a magazine article may be merely adding padding to a volume on the library shelf, for, without an index to recorded information, it is likely to become inaccessible. Nearly every one of that comparatively small band of workers who are patiently seeking to extend the boundaries of knowledge, to discover new and better methods of manufacture, or to invent and improve apparatus and machinery, must have realised the continual duplication of effort, which acts as an ever-present check to progress.

The lack of an extensive index to information was felt during the War; then machinery was hastily invented and methods of manufacture quickly devised, while the records of better apparatus and processes were lying buried on the library shelves. It is agreed that in peace and war a comprehensive guide to recorded knowledge would be an asset of the greatest value that would lead at once to important scientific and technical developments, while without it untold time and energy are being wasted throughout the world by the useless repetition of research and invention.

Various attempts have been made from time to time to collect, classify, and distribute information. A large number of publications are, or have been, devoted to the bibliography of special subjects; perhaps the greatest of all was the International Catalogue of Scientific Literature. There are, besides, many bureaux, both English and foreign, of divers types, engaged in the preparation of indexes to particular classes of information. Yet, in spite of all this activity, not the semblance of the desired key to knowledge is available.

This deplorable failure, which is restricting progress and prolonging unnecessary discomfort and inconvenience, may be due in great part to the lack of that which it is the purpose of bibliographies to supply; that is, information. For want of knowledge, bibliographical research is being undertaken everywhere, at home and abroad, without attention to the canons of bibliography or previous experience of its methods. Each abstracting or indexing body adopts a different system of classification and the abstracts or index slips are produced without regard to size, so that they cannot be mounted on cards and amalgamated with other bibliographies, and the information collected becomes hopelessly lost in thousands of separate parts. Moreover, every bureau indexes or abstracts papers that are done by, usually, a number of other bureaux, and only a fraction of the literature is covered.

The science of bibliography is not a subject of general study, and many scientific workers who realise the need of practical training in scientific method as well as knowledge of previous work appertaining to their special field of investigation, fail to understand that the same is true of bibliography. The would-be bibliographer must bring a scientific mind to the study of his task and must gain proficiency in bibliography by laborious practice. The indexing of scientific papers has also the added difficulty that the needs of scientific workers cannot be appreciated fully except by themselves. Thus an efficient index to scientific literature can scarcely be produced except by the application of a thorough knowledge of bibliographical science, wide experience in its application, and expert knowledge of the subjects indexed; that is to say, it is imperative that the scientific method be applied to bibliography.

Since the preparation of a complete index to published information involves the co-operation of many workers, it is necessary that a single system of classification should be chosen, which must be kept up-to-date by some central body. If, however, a definite classification were accepted and utilised by existing bibliographical undertakings, it would be possible to amalgamate their work into one series of cards which would go far towards the universal index desired. All information collected on a given subject would then fall together into one place to be available at need, and it would become apparent that identical information is being collected from the same periodicals by many different indexing agencies, and that information on a given subject is interesting to workers in many different branches of science or technology. By consultation, overlapping could be avoided, and energy, at present being wasted, could be used in indexing literature not dealt with hitherto.

The International Classification, described by Dr. S. C. Bradford elsewhere in this issue, is, ready to hand, such a scheme as is required for the preparation of a great index to recorded information, and no other suitable system is available. The general adoption of this code would make possible now the realisation of the index desired. Some thousands of bibliographies are in actual progress. At present their utility is very limited. But merely to number the bibliographical titles by the International Classification would make it possible to amalgamate them all into one index of the greatest value to mankind. The scheme has been utilised on the Continent as the basis of extensive bibliographies. The Classification is surely gaining ground and has received the support of the League of Nations. Recently, in Great Britain, the Optical Society has published an English translation of part of the Classification which has been used for the classification of the index to its *Transactions*. This can now be cut up, pasted on cards, and incorporated with other bibliographies numbered in accordance with the code.

When the International Catalogue of Scientific Literature came to an end, it was obvious that sooner or later the preparation of a comprehensive guide to scientific literature would have to be revived. The ideal solution to the problem has been suggested to be the building up of a National Science Library to take every important scientific periodical or publication together with a complete index to their contents, so that documentary research could be carried out in one building without waste of time journeying to different libraries.

As the Science Library at South Kensington contains an exceptionally extensive collection of scientific periodical literature, it seemed desirable that its resources should be developed so as to ascertain the possibility of realising such an ideal library. An organised effort is being made to augment the fine collection of scientific journals and transactions in the Library so as to make it as complete as possible. This has been so successful that periodicals are being added at the rate of a thousand or more a year, and the Library now includes between six and seven thousand of the items in the World List. The continuation of this undertaking, if possible on a somewhat larger scale, should lead in a few years to the gathering in the Library of a nearly complete collection of scientific periodicals.

After very careful consideration, the International Classification has been adopted in the Science Library for indexing the titles of its books and more important papers. The Library contains also sets of certain other bibliographies, as well as of some smaller undertakings based on the same system. All these are now being collected into one repertory, to which it will be possible to add any bibliographies that adopt this classification afterwards. The whole will be available for consultation in the Library together with the books, or from the index it should be possible to supply extracts by post at the cost of typing and postage.

The work of the past three years shows that the attainment of the first half of the ideal is possible. Its complete realisation would follow if it were possible for bibliographical undertakings generally to adopt the Decimal Classification of the Brussels Institute.

Atomic Structures.

(1) *The Progress of Atomic Theory.* By Dr. Albert C. Crehore. Pp. ii + 230. (London: Taylor and Francis, 1926.) 12*s.* 6*d.* net.

(2) *Die Welt der Atome: Zehn gemeinverständliche Vorträge.* Von Prof. Arthur Haas. Pp. xii + 130 + 3 Tafeln. (Berlin und Leipzig: Walter de Gruyter und Co., 1926.) 4·80 gold marks.

(3) *La fisica dei corpuscoli.* Per G. Gianfranceschi. Terza edizione. Pp. viii + 267. (Roma: Università Gregoriana, 1926.) 18 lire.

(1) THAT the Rutherford-Bohr atomic model, despite its remarkable success in explaining and correlating so many of the facts of physical and chemical science, is not yet universally accepted, is evident from a study of the first of these three books, the title of which will probably lead many who are unfamiliar with Dr. Crehore's writings to expect something quite different from what they will find. The book is really an account of the progress of the author's own particular atomic theory. Although we fancy that it will win few converts to his views, it is, nevertheless, not without interest.

Broadly speaking, Dr. Crehore believes, as so many of us would like to believe, that all atomic processes can be explained in terms of classical electrodynamics. It will probably be in the earlier chapters that the work will prove least convincing. Here the author describes the atomic models on which his subsequent calculations are based. We are told that the hydrogen atom consists of a nuclear charge of two units with two spheroidal electrons in contact with it, one on each side: similarly, the helium atom has a positive charge of four units, and on each side of this charge are two electrons closely bound to it. From these two fundamental atoms Dr. Crehore proceeds to construct the more complex atoms by a suitable arrangement of hydrogens, heliums, and cementing electrons. His atoms are more or less close-packed assemblages the linear dimensions of which are of the order of 10^{-13} cm.

The difficulties presented by such atoms are manifold, but if once the reader gets past these early chapters and accepts, even if only for the sake of argument, the hypotheses, he will find the subsequent chapters more logical. Indeed, in the development of his theory, Dr. Crehore shows no small courage and considerable mathematical skill in dealing on classical lines with these unconventional atoms. Perhaps the most interesting problem he sets himself is to explain why it is that atoms so small as 10^{-12} cm. should build themselves into solids in which they are separated by distances some ten thousand times greater than this. For this problem he claims a solution in the case of hydrogen.

The origin of a spectrum line of wave-length λ involves, according to this theory, an excursion of an electron to a distance $0{\cdot}05\lambda$. This applies equally to the optical and X-ray regions. In considering the latter spectra, the author emphasises the fact that this excursion is small compared with atomic distances in the solid. It is of interest to note, however, that recent direct determinations of long wave-length X-radiations would involve excursions considerably greater than the distance of closest approach of neighbouring atoms.

In spite of a bold defence of these atoms, which includes an explanation, based on them, of gravitation, there are still many gaps which will have to be filled and many difficulties which must be overcome before the majority of physicists will consider that the theory has progressed sufficiently far to replace that which is more or less generally accepted.

(2) If a course of Dr. Crehore has shaken, ever so slightly, the reader's faith in the conventional atom of to-day, it should be easy to restore it by a study of the second of these books. Dr. Haas is well known as a writer with a very considerable gift for clear and concise exposition, and this latest work worthily upholds this reputation. It is based on a course of lectures intended for a non-specialist audience and covers practically the whole range of modern atomic physics. That is a great deal to expect of a relatively small volume, but the author has selected his material with excellent judgment and woven it together into a convincing

narrative. There is no need to enter into the details of his presentation of the subject; suffice to say that he shows us that, whether we approach the problem of atomic structure from the point of view of optical spectra, X-ray phenomena, radioactivity, or any of the other lines, we are led to similar conclusions and to similar conceptions as to the nature of the atom.

If any one offers criticisms it will probably be the specialist, who may feel that the whole subject, as here presented, seems too simple, the interpretation of the facts too straightforward, the structure of the atom too obvious. This is a criticism which most authors will welcome. Too often a book which is perfectly sound from a scientific point of view is a very poor product when judged from a literary or artistic viewpoint, but Dr. Haas deserves our congratulations and gratitude for having written an account which is not only an up-to-date expression of the situation but also, above all, one which is readable.

(3) The third volume, by Dr. Gianfranceschi, is of a different type again. It is intended for the student rather than for the general scientific reader. As the title suggests, the author is concerned rather with the development of the electrical theory of matter than with the details of atomic structure. After preliminary chapters dealing with the basis of modern views of the structure of matter, he gives an outline of the kinetic theory of gases and its application to the theory of electrons. This naturally leads to a discussion of the problems connected with the passage of electricity through metals and kindred phenomena. Following the historical development, the author introduces the quantum by a short account of black-body radiation, and then proceeds to a brief description of modern theories of atomic structure and optical and X-ray spectra.

It might be expected that such a book would be full of somewhat abstruse mathematical analysis, but Dr. Gianfranceschi has succeeded in presenting his subject with the help of only such mathematics as every serious student of modern physics and chemistry may be assumed to possess. It is essentially a theoretical work, and experimental methods and results are introduced only in so far as they provide a basis for the theoretical discussion or a verification of the predictions of the theory. The fact that the book is now in its third edition is sufficient recommendation and sufficient proof that it has already proved its usefulness to a wide circle: without doubt, this new edition will be as popular as its predecessors.

The Endocrine Organs.

(1) *The Endocrine Organs: an Introduction to the Study of Internal Secretion.* By Sir E. Sharpey-Schafer. Second edition. Part 2: *The Pituitary, the Pineal, the Alimentary Canal, the Pancreas, and the Sex Glands.* Pp. xi-xxii + 177-418. (London: Longmans, Green and Co., Ltd., 1926.) 20*s*. net.

(2) *The Comparative Anatomy, Histology and Development of the Pituitary Body.* By G. R. de Beer. (Biological Monographs and Manuals, No. 6.) Pp. xix + 108 + 11 plates. (Edinburgh and London: Oliver and Boyd, 1926.) 12*s*. 6*d*. net.

(1) THIS volume completes the second edition of the well-known monograph upon the endocrine organs issued for the first time in 1916 and founded on a course of lectures (Lane Medical Lectures) delivered by Sir E. Sharpey-Schafer at Stanford University, California, in the summer of 1913. The second edition, in two volumes, has greatly outgrown its predecessor, and the second volume is the larger of the two, more than half of its bulk being devoted to the pituitary body. The other endocrine organs treated in it are: the pineal body, the duodenal and gastric mucous membranes in their relation to the production of secretin and gastrin respectively, the islets of Langerhans of the pancreas and the sex glands, including the interstitial cells of the testis, the ovary, and corpus luteum.

The histology of these organs is detailed and their structure illustrated by numerous drawings and photo-micrographs, all admirably selected and reproduced. Development of the organ is described in the case of the pituitary body, where its consideration is essential to a proper understanding of its differentiation with regard both to structure and physiological properties. The chemistry of the active principles produced by the organs and the history of the attempts to isolate them are recorded in so far as trustworthy evidence is forthcoming. Much, however, remains to be investigated in respect to the chemistry of the internal secretions, and the threshold of this subject has barely been reached as yet.

The physiological action of extracts of the organs, illustrated by admirable graphic records, and the history of their discovery, are fully detailed. The references to authors cited are exhaustive, and are given in foot-notes on the pages on which they are quoted, the value of the work being thereby greatly enhanced.

Clinical evidence bearing upon the effects of increase and decrease of activity of the organs has been wisely selected. The physician will find the book an invaluable one as an authoritative guide to the proper appreciation of what results may and may not be legitimately expected from the use of preparations of the endocrine organs as remedies. Unfortunately, the autacoids or self-remedies secreted by the endocrine organs do not lend themselves in all cases to a relatively simple method of employment such as is illustrated by the active principle of the thyroid.

The importance of the endocrine organs in physiology and medicine has long been established, but the grain is apt to be missed in the chaff, so abundant and varying in value is the literature of the subject. No one is better qualified than Sir E. Sharpey-Schafer to undertake the sifting required, and in these two volumes he has succeeded beyond praise in producing a standard work upon endocrinology which will be indispensable to the research worker and welcome to the physiologist and practising physician alike.

(2) This monograph, profusely illustrated by drawings in the text, and by special plates of photo-micrographs and one of coloured drawings, deals entirely with the morphology, histology, and embryology of the pituitary body. The various classes of vertebrates are considered, and in the concluding chapters the homologies of the gland are summarised, a scheme drawn up of its evolution, and observations made upon the types best fitted for experimental purposes.

The opening chapter gives an indication of the methods of preparation employed by the author. No mention is made of Flemming's solution, which, in the reviewer's experience, is by far the best fixative for the pituitary body, but requires a special technique in the subsequent procedure of staining. The author has entirely missed the histological evidence of secretory material in the pars nervosa, although it can be demonstrated in abundance in all types of vertebrates in which extracts of the posterior lobe yield an active pressor material. Harvey Cushing (Cameron Lectures, 1925) has indicated the importance of this material in the human pituitary, and has commented upon the surprising way in which it is ignored by many histologists.

Few references to the literature of the subject are made in the text, and the reader will find it impossible to distinguish between the original observations of the author and what has already been noted by others. This is a serious fault, and deprives the book of much of its value as a basis for further workers. An appendix gives a bibliography of works upon the pituitary published since 1913.

Most of the illustrations are original. The drawings are helpful, but references to them in the text are not always accurate; *e.g.* on p. 12 the reader is referred to Fig. 28 for an illustration of variations in the Golgi apparatus of the cells of the pars anterior of the mammalian pituitary, and on turning over a number of pages finds a line diagram of a transverse section of a fowl's pituitary. The photo-micrographs are far too crowded, and although well reproduced, lose in value because of their arrangement and the absence of an adjacent description.

To turn from criticism, it must be admitted that the author has recorded much work that is praiseworthy. Methods have been devised which appear to enable a differentiation to be made between pars intermedia and pars tuberalis. He has much to say that is interesting although one may not always agree with it, and his views upon the homologies and evolution of the gland cannot be lightly dismissed. P. T. H.

Our Changing Earth.

Our Mobile Earth. By Prof. Reginald Aldworth Daly. Pp. xxii + 342 (15 plates). (New York and London: Charles Scribner's Sons, 1926.) 21*s*. net.

PROF. DALY of Harvard once again has presented in book form matter of geological interest gathered from all parts of the world, and has supplied the desirable connective tissue of theory and speculation. The present work is based upon a course of popular lectures given at the Lowell Institute of Boston. Below the surface, however, it is easy to realise that it has been prepared for the serious student as well as for his lay brother. There is something of the fascination of Lyell's "Principles" in these traveller's tales, each one with its moral; and the suggested references listed chapter by chapter at the end of the volume will be found most useful. The 187 illustrations, too, are excellent; and an author's note invites their reproduction except where covered by previous copyright.

To begin with, we are introduced to earthquakes, with proper emphasis on their scientific importance as well as their frightfulness—fewer people are now killed by earthquakes than by motors. The localisation of earthquakes in the Tertiary mountain belts is explained as a result of up-and-down and sideways adjustments of already folded masses. Observed surface displacements are discussed with copious illustration. In passing, one may perhaps protest against ring-cracks being referred, in Fig. 10, to "torsion of the ground." These particular cracks are surely analogous to countless ring-fractures that a few years ago used to develop through settlement in relation to old shell-craters in Flanders. But to return from this aside, Daly not only illustrates surface faulting in connexion with the 1906 San Francisco earthquake, but also shows how the final snap was preceded by a more distributed distortion that has been traced in observations of the U.S. Coast and Geodetic Survey.

Daly next explains seismograms and the three kinds of earthquake waves distinguishable in these records. We are now getting to the heart of the subject. Advancing the usual arguments, our author claims that the continents are great discontinuous masses of aggregate granitic composition, and that they float in iceberg fashion with foundations immersed in crystalline basalt. He further suggests that below the crystalline basalt is a circum-mundane layer of *glassy basalt*, in which high temperature inhibits crystallisation. This conception has two important bearings upon volcanic and tectonic problems: it entails a limited inversion of the law of increasing density with increasing depth; and it also gives a higher subcrustal plasticity than might otherwise be expected. Probably many readers will hope that Daly will recast his theory to make his density inversion local as well as limited.

A chapter naturally follows on volcanic action. It is a valuable résumé, with much stress laid on Kilauea in general and gas-fluxing in particular. St. Helena is also mentioned as a geological paradise, and regret is expressed that Napoleon did not realise his opportunities in this direction.

An instructive attempt is made to disentangle earth and sea movement in comparatively recent phenomena of emergence and submergence. Jamieson's interpretation of isostatic earth-movement in connexion with ice-load is accepted as of prime importance for the understanding of the raised beaches of glaciated lands. On the other hand, a low raised beach, which Daly has traced along much of the shores of the Atlantic and Pacific Oceans, is attributed to a Neolithic withdrawal of water to augment some still existent ice-sheet. Similarly, Darwin's submersion theory of atolls is brought into relation with release of water during the wane of the glacial period. It would be interesting if some other isostatic expert were to approach Darwin's theory fortified with the apparently obvious assumption that all oceanic volcanic islands must in course of time subside.

The mountains of the globe are divided by Daly fairly comfortably into Mid-latitude-Mediterranean and Circum-Pacific zones. The nature of mountain folding and thrusting is illustrated, *inter alia*, by Fig. 148 of an overthrust outlier, Chief Mountain, Montana. In scenic expression it rivals the best of the Swiss *klippes*. Daly's outlook upon mountain problems is naturally reminiscent of the writings of Dana, James Hall (of New York), and Dutton, but it has notably original features. Here we need only point out that Daly joins Osmond Fisher, Dutton, Taylor, Wegener, and many modern alpinists in revolt against the old earth-contraction theory of mountain origin. He adopts instead the continental drift hypothesis, and adds new features. In outline, his statement is as follows:

(1) Continental drift is of the nature of a gigantic landslip—exceeding in scale the tectonic landslips envisaged by Schardt or Reyer.

(2) A cause is suggested for the continental doming that is supposed to have preceded continental slipping.

(3) The glassy substratum makes slipping easy.

(4) The slipping continents crumple marginal geosynclines.

(5) The glassy substratum allows of subsidence of crust-blocks beneath crumpling geosynclines, and the fusion and expansion of these blocks is responsible for eventual elevation of mountain chains.

A feature which continually crops up in Daly's discussion of mountains is an assumed lag between crumpling and elevation. In Europe, however, the evidence distinctly favours contemporaneity of these two phenomena (with, of course, later repetitions of upheaval in response to erosion as explained by Fisher in 1881). For example, the Tertiary Flysch and Molasse of Switzerland derived most of their material from already elevated Alps that were actually travelling. The travel was so real that the Flysch was in due course entirely incorporated in the Alpine chain, and even the Molasse, though it formed later and farther north than the Flysch, now lies marginally overturned and over-ridden.

The Band Spectrum of Mercury from the Excited Vapour.

IN my letter dated Mar. 1, which appeared in NATURE of Mar. 12, p. 387, it was stated that the 'forbidden' line λ2270 appeared in the excited vapour in association with the band spectrum.

I now find that the other 'forbidden' line at the computed position λ2655·60 also occurs in the excited vapour, and much more strongly than λ2270. The observed position of the line is λ2655·73. This measurement might doubtless be improved upon, but the line is very definitely on the less refrangible side of the line λ2655 13 in a comparison arc spectrum. The 'forbidden' line is absent from the latter, and, so far as I know, it has not been observed before in any circumstances.

RAYLEIGH.

Mar. 8.

Truth or Convenience.

DR. WILDON CARR's letter in NATURE of Feb. 5, p. 199, serves as a reminder that the mathematics of relativity is one thing and the philosophy based on it is another; so I take advantage of the opportunity to comment controversially on a few philosophic points, and especially to protest against a comparatively recent anti-scientific tendency to teach that we are not making an attempt to ascertain actual truth about the universe, but only to formulate propositions that are practically helpful and convenient.

In explaining the theory of relativity in ordinary language, stress is usually laid on the 'observer,' and at one time we were told that metaphysical ideas were evaded by attending solely to what could be observed with the aid of measuring instruments, and that thus physicists might be placated, since they were dependent on laboratory measurements for all their knowledge. But if physicists had proceeded solely on that basis, they would not have got very far in their generalisations and theories. The laws and conceptions of physics, like those of mechanics and geometry, are surely ideal; the exact truth of their propositions holds, not in the world of experience, but in an ideal world the axioms of which are infinitely true if true at all; experience might enable these theorems to be rejected as false, but their accuracy could not be tested by any precision of measurement, which must be limited to the fifth or sixth or perhaps the ninth decimal place.

The laws of motion, for example, and any other simple generalisation like Ohm's law, originate as hypothetical challenges, to be definitely disproved if possible, or to be verified approximately, or to be modulated by subsequent refinement, or to be applicable subject to certain conditions. Meanwhile they are taken as precisely true. Newton's law that acceleration is proportional to resultant force was treated as exact; the minor dependence of the ratio on speed was a discovery two centuries later. The constant ratio of e.m.f. to current in a metallic conductor may be modified by many circumstances of which the molecular disturbance caused by the current itself is chief. The law, moreover, may be found to apply to liquids, and be inapplicable to rarefied gases. Departure from an ideal law in any given case is a matter of measurement.

Truth is in the ideal. The actual world is an approximation thereto. No one has ever encountered an exact circle or triangle, but the Euclidean propositions apply to actuality as near as makes no matter. That is perhaps the excuse for saying that we do not aim at truth; but it is a bad excuse. We always aim at truth beyond the range of our experience or measuring achievements. Absolute truth may be an unattainable ideal, but it is our clear and permanent aim.

Similarly, the relativity axioms are incapable of any but approximate verification. They, too, belong to the ideal. This applies obviously to the equations, which as they stand are superhumanly accurate, but it also applies to the verbal interpretation or elucidation of such equations in terms of different observers. On no practical grounds can it be held that measurements made by an observer flying past the instruments, or the thing to be observed, are just as good as those made by one who is sitting still, and that we have no reason for preferring the observations of one more than those of the other. I take it that all the modes of statement in which different observers are mentioned are merely attempts to put into words, and thus make clear to literary philosophers, the meaning (say) of the Larmor-Lorentz transformation. From this point of view no doubt an 'observer' can be replaced by a photographic plate, except that neither a photograph nor anything else has a meaning until it is interpreted by a mind. But so far as the record is concerned, it does not matter whether the images are on the retina of the eye or on something else: the ultimate interpreter, in either case, is interpreting a physical record.

The exposition of the basal principles of relativity by Dr. Jeans in the new volumes of the "Encyclopædia Britannica" is a masterly production, and as he does not enter upon philosophy, save in a few subordinate sentences near the end, no fault can be found with it. But when it comes to an application of those principles to philosophy the ground is far less secure. The subordinate sentences I refer to in this fine article are where he says:

> "Relativity teaches us that this velocity [$c \pm u$] is always precisely c, and this in itself disposes of the ether of Faraday and Maxwell."

But surely the teaching of relativity on that subject is an assumption, based no doubt upon negative experiments and highly plausible, but not really verified; hence its force as an abolishing agent is by no means overpowering. It might even be said that the relativity rule for compounding any two velocities, u and v, essentially implies a medium in which the motions occur, because its characteristic constitutional velocity c is inevitably involved. Nevertheless it may be fully admitted that an ether subject to the ordinary laws of dynamics, so as to be illustrated by mechanical models, has had to be abandoned. All our science and natural laws have hitherto been limited to matter. Directly we go beyond that we are in the dark: somewhat literally our senses leave us. That is why I presume we are so loath to admit the existence of anything immaterial.

Again, it is said that it "is impossible to discriminate between gravitational and centripetal acceleration"; but surely one has relation to an axis, the other to a centre. At any given place discrimination may be impossible; but taking the whole surface of the earth into consideration it is not impossible. It is well known that they have been and must be discriminated: so, of course, the above is not Dr. Jeans's meaning, unless absolute rotation is abolished. But it is apt to be taken as his meaning, and so force or constraint gets abolished too.

Again, it is sometimes wrongly understood that two events are said by relativists to be simultaneous when a ray of light can be present at both. Or in the words of the philosophical article immediately following that of Dr. Jeans: "If a ray of light can move so as to be present at both events the interval is zero." Thus it might be understood that the flash of a pistol was simultaneous with its impression on the eye; or that the outburst of a solar flame or a new star is synchronous with the formation of its image on a plate. That is doubtless the appearance, but it has no reality. Every one really allows for time taken by the messenger. 'Interval' is a new technical term, involving both space and time, which may as it were partly or wholly cancel each other. The statement quoted above is only an interpretation of the usual expression for an interval ds in the so-called four-dimensional equation,

$$ds^2 = dx^2 + dy^2 + dz^2 - c^2dt^2,$$

with $ds = 0$ when light is concerned. In the interpretation of this equation, in which the velocity c has been introduced, that velocity is often called 1, and eliminated; but we cannot eliminate it from reality and regulate the nature of time or the sequence of events to suit any physical traveller. Zero interval does not mean simultaneity in time. The observer ought never to be allowed the last word. I suppose it may be truly said that thunder and lightning are really and truly simultaneous; but that cannot be the impression of any observer. Ascertained truth is the result of a mental operation superposed on mere observation. One observer may be as good as another, but an interpreter surpasses both.

Doubtless these objections are minor ones, and are not likely to be admitted without emendation; but there is a real tendency, initiated apparently by Mach, and pursued by Poincaré, to contend that physical generalisations are not so much true as convenient. And further, that all manner of absurdities can be tolerated, if they help us to arrive at results. Well, I admit that they can be tolerated in an interim manner; as in any consistent system of mathematics, $\sqrt{-1}$ and the rest are very useful; but they always disappear from the final result, or at least from the interpretation of that result. The tendency that I fear is that some of the absurdities will be retained by philosophically minded interpreters, and will be foisted into their scheme of reality. For example, in dealing with the quantum drop of an electron from one orbit to another, some writers seem willing to contemplate the extinction of an electron in one place and its re-creation in another; so that its world-line, instead of being continuous, is dotted. (I see that this very thing is illustrated in a letter immediately following Dr. Wildon Carr's.) Again I find in a review of a book by Prof. G. N. Lewis in Nature of Feb. 12, p. 228, an assumption that destination affects emission, or that an atom only emits light to or towards another atom; or in other words, "that we can influence events which are already past." So that, for example, the dark spaces in interference bands are to be accounted for by the light that would have fallen there being actually not emitted. This last contention, however, unlike some of the others, is demonstrably false; for we know that interference is only redistribution, and that extra light is accumulated in the bright spaces. Some popular statements about interference, however, have led people to suppose that light destroys light, not only locally but absolutely, in contradiction to the conservation of energy. Trivial errors like this may be of no consequence; but somehow people are led to say, what is actually said on p. 228, that the question of true or false "has no meaning in science. All that one is concerned with, as in the case of all scientific theories, is its usefulness." I venture to urge that contentions of that kind ought to be stigmatised and rebelled against as heresy.

There is a further but more recondite contention that our great physical generalisations (the conservation and relativity laws, for example) are not so much laws of Nature as identities, when properly regarded with full knowledge, so that their contrary is inconceivable. There may be some important philosophic truth in this, and perhaps it might be extended to include everything that is; so that, regarded from an impossible point of view of full and complete knowledge, everything is inevitable and could not be otherwise (unless this is limited to the inorganic world, and is not true of life and mind). However that may be, the discovery of these identities is the achievement of scientific exploration, and surely such identities are a real truth about the nature of things, and not mere human conveniences of expression. Regarded as conveniences, some relativity statements rather fail by not being convenient.

I know that this is a presumptuous letter, open to attack from many sides; but I do want to enter a protest against the idea creeping into scientific philosophy (not perhaps sufficiently guarded against by that admirable philosophic combination, the late James Ward and J. H. Poynting) that we are not out for truth, but only for handy methods of formulation; and, further, that we can contemplate absurdities, geometrical and other, not only as auxiliary and contemporary and intermediate aids, but also as representing something actually existing in the universe, although repugnant to our mental make-up. For mind, after all, is part of the universe,—by it our laws are formulated, and on it our test of truth depends. Minds are not infallible, however. It is therefore necessary to be cautious in stigmatising anything as an absurdity, lest its absurd aspect be only relative to our own incomplete experience and inadequate knowledge. Oliver Lodge.

Radio-activity and the Heat of the Earth.

While recognising the importance of the evidence brought forward by Dr. Lawson in Nature of Feb. 19, p. 277, I cannot agree that it is sufficient to demonstrate that only an insignificant portion of the energy emitted by radio-active elements in rocks is expended in effecting changes in the surrounding minerals. He states that when such elements are placed in glass tubing, the energy absorbed in producing modifications in the glass does not amount to more than one per cent. of the total given off and is probably not more than about a tenth of this value. He infers that a similar state of things must prevail where biotite mica instead of glass is exposed to the radio-activity, and this in spite of the fact that on heating the pleochroic spheres (usually referred to as haloes) that result, they "exhibit the phenomenon of thermo-luminescence," but claims that "the energy so liberated does not produce catastrophic results, and is manifestly small." The last statement is, to say the least, by no means obvious. The question at issue is simply quantitative, and it therefore seems to be dangerous to argue that because glass tubing containing about 70 per cent. of silica and a certain amount of lime and soda absorbs but a small proportion of the radio-active energy, this will also be the case with biotite containing, say, 38 per cent. of silica with smaller amounts of alumina, iron oxide, potash, and titanium oxide. That the alteration in the biotite caused by the radio-activity is very considerable follows from the fact that, as shown by Dr. Brammell of the Imperial College, the pleochroic spheres persist even when the biotite has been converted by pneumatolytic agencies into a substance practically identical with muscovite. He also found that it was necessary to keep biotite at a dull red heat for about six hours to render the 'haloes' invisible. During that time a very large amount of heat might be released without "catastrophic results."

Recently, records have been published of a deep boring at Dubbeldevlei in the Cape Province of South Africa (about Lat. 30° 30′ S. and Long. 21° 35′ E.), and they deserve consideration in connexion with this question. It reached a depth of approximately 5080 feet, and a survey by Prof. G. A. Watermeyer (*Trans. Geol. Soc. S. Africa*, vol. 26, pp. 65-7, 1924) showed that the depth could not be in error more than 0·3 of a foot. Temperature measurements were made by L. J. Krige and H. Pirow with the greatest care (*ib.* pp. 50-64). Down to 2137 feet the rocks consisted of horizontal Ecca and Dwyka beds, shales, with occasional dolerite sills, and tillite. Then came 550 feet referred to the Fish River Series, correlated with pre-Cambrian Pretoria Series. The remainder of the boring was in the ancient granites and gneiss which outcrop about fifty miles to the northward. They are widely extended in South Africa, not only at the surface but also below ground, as evidenced by fragments in the Kimberlite pipes (Du Toit, "Geology of South Africa, p. 44, 1926). They probably underlie all sediments except the primitive metamorphic rocks of pre-Witwatersrand age, into which they appear to be intrusive, and extend downwards for a depth of several miles at least. Being of acid composition they are presumably rich in radio-active substances. They must contain, too, a considerable amount of potassium, which Dr. Lawson claims as being radio-active.

The average temperature gradient for the whole depth of the boring was 1° C. in 31 m., but varied from 1° in 18·3 m. to 1° in 51·8 m., mainly in accordance with the conductivity of the local rock. In the granite and gneiss, the conductivity of which lies between 0·005 and 0·006, the average gradient was 1° in 45·4 m. In shale the gradient was at its highest, 1° in 18·3 m., for the conductivity of shale is stated to be only 0·0023. In the Witwatersrand mines the gradient is so low as 1° C. in 112·8 m., the conductivity of vein-quartz and quartzite being 0·0095, and that of pure quartz more than twice as much.

It is remarkable that the presence of extensive granite and gneiss in the lower 2400 feet of the bore, and for a far greater depth below, seems to have had no appreciable effect on the gradient. Unfortunately, no determination of the radio-activity of the rocks traversed appears to have been made. It is to be hoped that this will be carried out, as the cores are apparently still available.

JOHN W. EVANS.

'Seizure' with Sliding Surfaces.

IN his letter to NATURE on "The Polishing of Surfaces" (Feb. 19) Mr. N. K. Adam refers to Hardy's work on static friction, showing the tearing away of surface particles of glass when one glass surface slides over another glass surface. In a leading article, *Engineering* (Jan. 23, 1925) emphasises the difficulty in understanding how forces of cohesion, exerted through surface layers, can ever be great enough to overcome the forces of cohesion between a particle of glass on the surface and the particles of glass immediately below the surface, in order that a scratch may result. The writer in *Engineering*, as an alternative explanation, has recourse to ideas with regard to friction which Prof. Muir tells me were described so long ago as 1776 by Oliver Goldsmith in his "Survey of Experimental Philosophy": "The little risings in one body stick themselves into the small cavities of the other in the same manner as the hairs of a brush run into the irregularities of the coat while it is brushing. If the bodies slide one over the other, the little risings of one body in some measure tear or are torn by the opposite depressions."

What appears to me as a better explanation of the phenomenon of 'seizure' is afforded by the suggestion I made with regard to the polishing of surfaces (NATURE, Sept. 4, 1926), namely, that actual fusion of the surfaces occurs. The temperature at the point of seizure (one of the many points of 'contact' between plane surfaces) rises so high that actual fusion of the glass occurs across the surface layers, with subsequent rupture. It is only at first sight that this hypothesis seems extravagant, but Mr. N. K. Adam's reference (in the letter referred to above) to the "small thermal conductivity of the material," and his comments with regard to points of contact, indicate that some further explanation of the manner in which the thermal agitation is set up is desirable.

Space demands brevity, but there should be little difficulty with regard to the points of contact. Even such a material as wash-leather cannot possibly adjust itself to molecular irregularities. With regard to the setting up of the molecular agitation, it may be helpful if I refer again to the analogy of originating sound vibrations. My attention has been directed to a calculation made many years ago (I do not know by whom) showing that the natural frequency of sound or elastic vibrations of a particle of molecular dimensions is a high temperature frequency. Thus frequency $= \sqrt{E/\rho}/2l = \sqrt{10^{12}}/10^{-8} = 10^{14}$ per sec., and the frequency of the dominant wave length in black body radiation at a 'bright red temperature' is about 10^{14} vibrations per sec.

In conclusion, I would comment on Mr. Adam's statement that "Clearly the random removal of particles . . . from one point of the surface to another, must result in forming an amorphous layer, if continued long enough," by remarking that the ends of a freshly fractured glass rod do not cohere when pressed into contact again, and I do not understand how small fragments of glass in the polishing process can form an amorphous layer, polished or otherwise, without the intense molecular agitation or increase in temperature which gets rid of the surface layers.

On the Volatility of Borax.

IN a discussion of the standardisation of hydrochloric acid with different standard substances (*J. Amer. Chem. Soc.*, 70, 1772, 1926), I made the following remark: "After the substance [borax] had been dried at 200°, the crucible was placed in an electric oven at a temperature of 700-750°, until constant weight was attained. When afterwards it was heated at 800°, at which temperature the salt fuses, the weight did not change. We cannot confirm the statement of H. V. A. Briscoe, P. L. Robinson, and G. E. Stephenson (*J. Chem. Soc.*, 122, 150, 1925), who state that fused borax loses sodium oxide. Even after the substance had been heated for two hours at 800° the weight did not change."

Prof. Briscoe and P. L. Robinson (NATURE, 118, 374, 1926), remark on this statement that the fact is well established that borax is volatile at high temperatures. They even were able to show in a qualitative way that fused borax is decomposed at higher temperatures. They say: "The inside of the silica muffle used for the fusions of borax in our investigation was completely coated with a white opaque enamel, about 0·06 inch thick, of a product of a reaction between the volatilised material and the silica."

As there is such a discrepancy between Briscoe's and my own results, I repeated the latter, but again I found a negligible loss in weight after two hours heating at 800°. Now Prof. Briscoe and his collaborators say they fused the borax in a *platinum dish* (large surface), in the electrically heated muffle in *a current of air* free from carbonic acid and dried over solid caustic potash. In total they heated it for 2-2½ hours. Hence they worked under conditions very favourable for volatilisation. In my experiments the borax was heated in a covered platinum crucible (surface of the fused borax about 2·5 cm.), without passing a current of air over it.

In order to check the results formerly obtained we heated about 3 gm. anhydrous borax in the electric oven under the same conditions as described.

We continued the heating for about fifteen hours at 880°, and afterwards twenty hours at 940°. At different intervals the borax was weighed (It is unnecessary to take precautions against hygroscopicity of the anhydrous salt, as the melt of borax with its small surface attracts water from the atmosphere very slowly. Even after standing in an open crucible overnight in the balance, the weight did not change.) From the results it appeared that the borax lost at 880° 0·16 mg. per hour, and at 940° 0·23 mg., due to the volatilisation.

We must therefore confirm the statement of Briscoe and his collaborators, that fused borax is volatile. *On the other hand, it is evident that under favourable conditions* (heating in a crucible without passing over it a current of air, and at a temperature of about 800°) *the loss due to the volatilisation of sodium oxide is so small that it is negligible, even for most accurate analysis, if the heating is not prolonged for more than two hours.*

The Coat of Sheep.

In an important work, "Das Haarkleid des Menschen," published in 1908, Dr. Hans Friedenthal points out (1) that in man the coat between the fourth and fifth month of development consists entirely of fine wool fibres, and (2) that shortly before birth there appear among the fine wool fibres strong pigmented fibres with a pith or medulla, *i.e.* fibres corresponding to the coarse fibres forming the outer coat of wild sheep. Hitherto it has been assumed that the simple pithless fibres forming the coat of the Merino and other fine-wooled sheep are modified true hair fibres—hair fibres that have lost their medulla, from which, according to Bowman (the author of the standard work on wool), "the medulla has been bred out." From an investigation which has been in hand for some time on the structure of the fibre forming the coat of sheep, it has been ascertained that in sheep, as in man, the first coat consists entirely of simple pithless fine-wool fibres.

In the case of sheep, the gestation period lasts about twenty-two weeks. Though at the end of the twelfth week of development there are only a few fibres on the lips and at the tip of the tail, there is a complete coat at about the end of the fourteenth week. The fibres forming the first coat vary in length. In some areas they are so short that they are inconspicuous, in others they are nearly a quarter of an inch in length. The long fibres in sheep at the end of the fourteenth week, like the long eyebrow fibres in the human embryo, are obviously wool fibres. Though up to the middle of the fifteenth week the coat consists entirely of fine pithless wool fibres, at the end of the fifteenth week, more especially in the embryos of Highland Blackface and other coarse-wooled breeds, short coarse true-hair fibres with an interrupted or a continuous medulla are found among the fine-wool fibres of the first coat. As the development proceeds the coarse medulated fibres increase in number, and even in some fine-wooled breeds attempt to form an outer coat. In Europeans, as Friedenthal points out, there is, even in old age, usually a vestige of the first coat of wool.

In all wild sheep there is during winter a complete inner coat of very fine wool and an outer coat of coarse hair. Even in present-day domestic fine-wooled breeds there is always, on the head and limbs, a remnant of the original ancestral outer coat of coarse hair.

From this short account of the investigations in hand, it follows that a study of the coat of sheep during fœtal life lends no support to the view hitherto held by Bowman and others that wool is hair from which the pith or medulla has been bred out, but shows that wool is a distinct and primitive type of fibre different alike from fur and hair.

Non-Magnetic Films of Iron, Nickel, and Cobalt.

The letter by Mr. Hanawalt and Prof Ingersoll on "Non-Magnetic Films of Iron, Nickel, and Cobalt" (Nature, Feb. 12, p. 234) raises a number of interesting questions.

Oseen's explanation (*Z. fur Phys.*, 32, 940; 1925) of the properties of the previously announced non-magnetic films of nickel was based on the supposition that 'non-magnetic' signified not only the loss of ferromagnetism but also of the magnetic moment of the nickel atom itself. An electronic rearrangement but no other change was postulated as a result of which the nickel atom obtained a completely symmetrical configuration, thus leading to a non-magnetic film in the above double sense. It may be pointed out that, while such an explanation could be extended to the case of iron, it would not be applicable for cobalt, as this atom contains an odd number of electrons.

It is not possible to state definitely from the data so far published whether the term 'non-magnetic' should be interpreted as in Oseen's paper or merely as indicating a loss of ferromagnetism as it is apparently intended. So far as the physical nature of the non-magnetic films is concerned, it seems that these may differ from the ordinary metals in bulk in that (1) the metallic atoms are farther apart; (2) chemical combination probably of a rather loose type may have taken place; and (3) there may have been an electronic rearrangement in the metallic atoms. (1) is shown to be the case from Hanawalt and Ingersoll's observations, and (2) is rendered probable. The reality of either (2) or (3) or both could be determined if it were possible to state whether the material of these non-magnetic films is diamagnetic or paramagnetic, and in the latter case, by measuring the susceptibility over a range of temperature, to evaluate the magnetic moment of the metallic atoms. The occurrence of paramagnetism would be consistent with the existence of change (1) with or without (2) and (3). A knowledge of the actual magnetic moment would probably enable a definite decision to be made as to the reality of changes (2) and (3).

If diamagnetism were found and the films of iron, cobalt, and nickel are really of a similar nature, then it would be very probable that all three changes had taken place. The metallic ions would then be in states which might correspond to that of iron in, say, $K_4Fe(CN)_6$, cobalt in most co-ordination compounds of tervalent cobalt, and nickel in, say, $Na_2Ni(CN)_4$.

The Action of 'Antiknocks.'

THE following conclusions, amongst others, have been reached during an investigation on the effect of 'antiknocks'—such as lead tetraethyl—on 'knocking' in petrol engines:

(1) Antiknocks do not influence detonation in rapid combustion mixtures (*Proc. Roy. Soc.*, 114, 137, 1927).

(2) They function in the initial stages of the combustion as negative catalysts. In the slow combustion of a hydrocarbon, aldehydes are produced which readily form peroxides, which auto-catalyse or induce oxidation of the earlier stages. If these are removed, combustion proceeds more slowly. By reason of such effects on the processes of slow combustion preceding ignition, 'antiknocks' influence greatly the igniting temperature, particularly in the case of aldehydes. Similarly they effect those same processes which occur at a flame front in a comparatively slow burning mixture.

(3) Those metals which give effective organo-metallic antiknocks are found to be capable of forming higher oxides. Such metals as potassium, which form peroxides in equilibrium with other oxides at about 400° C. are very effective. Non-oxidisable metals such as gold are ineffective. The unstable peroxide formed in the combustion of the fuel and the metallic peroxide are considered mutually to destroy each other. The rate of destruction of the positive catalyst is greater than its rate of production, so that combustion is delayed. The metal atoms in a state of incipient oxidation are thus the effective anti-catalysts.

(4) A purely organic antiknock like aniline is effective for the same reasons; only those types of organic substances are effective as antiknocks as have been shown to be effective in retarding the oxidation of certain aldehydes at normal temperatures in the liquid phase. The mechanism adduced to explain their action in such circumstances by Moureu and Dufraisse is similar to that which we have given above. Such organic antiknocks themselves undergo combustion and are destroyed, a larger quantity of the negative catalyst being therefore required for the same effect.

(5) Both for 'ignition' and 'knocking' there is a condition of sensitiveness to change of reaction rate, and the effect of 'antiknocks' is in general much the same on the two phenomena. The views given are supported by the effect of such substances (aldehydes, organic peroxides, etc.) which promote knocking or favour ignitibility.

These conclusions elaborated and the experimental data which suggest them, will be detailed in papers which it is hoped soon to publish.

Electron 'Reflection' *in Vacuo.*

IN the *Proceedings of the Cambridge Philosophical Society* (Pt. 5, vol. 23), just received, there is an interesting article by Mr. C. F. Sharman on the application of the magnetic spectrum method to the study of secondary electron emission.

Several investigations of this type are now and have been for some time in progress in this laboratory, and we hasten to point out that at least one of our results obtained within the last six months has a bearing on Mr. Sharman's work. We find, in accord with him, that a fraction of the electrons emitted from a filament and accelerated towards a reflecting plate under potential V are 'reflected' with energy corresponding to that full potential V, and that energies immediately less than about 12 volts below V appear to be absent in most of the spectrum photographs taken. Generally speaking, there is a continuous spectrum starting at $(V - 12)$ and extending down to lower energies in an impartial manner. One of the two hundred or so photographs so far obtained is here reproduced (Fig. 1) with a potential scale in volts added for comparison. The sharp-edged black line in the spectrum at 238 volts shows the 'reflection' (from a copper target in this particular case) of the full energy electrons; there is then a white space, and thereafter a general reflection of all energies below about 226 volts. We think that this gap of 12 volts is in all probability real and not instrumental, as Mr. Sharman suggests. Our experimental results are in agreement with a short note by J. Becker (*Phys. Rev.*, 1924), in which during an investigation into the photoelectric emission from various surfaces a very similar effect was recorded.

Is Darwinism Dead?

REFERRING to the correspondence in NATURE of Feb. 19, p. 277, Mr. H. Belloc writes to say that his statement regarding the impossibility of birds having been evolved from a reptilian form was based on Prof. L. Vialleton's "Membres et Ceintures des Vertébrés Tétrapodes" (1924), not, as Sir Arthur Keith had supposed, on that author's "Éléments de Morphologie des Vertébrés" (1911). The mistake seems to us to be immaterial to the question at issue—namely, "Is Darwinism Dead?"—and we suggest that it would not have occurred if Mr. Belloc had followed the usual practice of giving references to his authorities.

As to the particular point under discussion, it has been referred to the leading authority upon the subject, who replies: "It is absolutely certain that the birds came from reptiles." EDITOR, NATURE.

The Sun, the Earth's Atmosphere, and Radio Transmission.

By Prof. S. Chapman, F.R.S.

THE immense present-day importance of radio communication has directed the attention of a wider circle than ever before to the conditions prevailing at great heights in the atmosphere. Even to the professional meteorologist it seemed formerly that what happens above a height of 30 or 40 kilometres has no bearing on the practical affairs of humanity, however interesting the problems of these upper levels might be to the pure theorist. Almost the only influence of these levels upon the technical operations of mankind seemed to consist in the occasional interruption of telegraphic communication at times of great magnetic storms and auroral displays; the interference was pretty clearly due to currents induced in the earth and the cables by the rapidly varying magnetic field, but the direct association of the latter with the upper atmosphere was somewhat hypothetical, though the auroræ were quite indubitably atmospheric phenomena.

Now that signal transmission is not confined to cables, and electromagnetic oscillations over a wide range of wave-length are sent out into space, the upper air assumes more direct importance, for it is known that a large part of the energy transmitted to distant points travels intermediately at high levels. The manner in which the waves are affected in the upper levels is already partly understood; the rate of propagation is increased by the presence of ions, so that if the ionisation increases with height the upper part of a wave front travelling at an upward inclination to the horizontal is tilted forward, and the wave train may thus be refracted downwards again, quite sharp angles of bending being possible. At the same time, some of the energy of the wave, communicated to the ions, is lost by the latter during collisions with surrounding molecules; if the mean free path of the ions is short, and collisions frequent, the energy of the waves may be rapidly absorbed; the absorption increases with the density of the ionised layer, and is greater for long (low frequency) waves than for short waves. Moreover, the earth's magnetic field deflects the ions while they are oscillating under the influence of the waves, and brings about a change of polarisation of the waves, which is responsible for some of the errors in direction-finding by wireless.

These facts make it clear that changes in the ionisation of the upper atmosphere have an important bearing on wireless transmission, and should be carefully investigated in order that, if possible, the methods of signalling may be adjusted to the changing conditions. Probably in the future the upper atmospheric phenomena will become known by wireless investigations themselves with a thoroughness and detail not otherwise attainable—the results already achieved seem to promise this. But, at least in these early days of such work, some help towards the understanding of wireless problems may be gained from the knowledge slowly accumulated during three or four generations by the study of solar phenomena, auroræ, and terrestrial magnetism.

The ionisation of the atmosphere at high levels may be partly due to the penetrating radiation studied by Kolhörster, Hess, and Millikan, or by the runaway electrons the probable occurrence of which during thunderstorms has been pointed out by C. T. R. Wilson. It seems unlikely, however, that the ionisation thus produced is comparable in importance with that due to solar action. The magnetic variations are intimately connected with the ionisation of the upper atmosphere, and indicate its general distribution and its more important changes, which are unmistakably associated with the state of the sun, or its presentation towards the earth. Further study may reveal magnetic phenomena indicative of ionisation unconnected with the sun, but it appears improbable that such can be of the same order of magnitude as that of which the sun is obviously the cause.

The sun ionises the upper air by two independent agents. One of these travels rectilinearly and falls only on the hemisphere of the earth which faces the sun, that is, on the day or sunlit hemisphere. Many facts indicate that this agent is ultra-violet radiation, absorbed in the upper atmosphere, principally by ozone, itself produced by the first stage of such absorption; another consequence is that the temperature of the layer in question (extending upwards from about 50 km. height) is raised above that of the air at ground-level. As the revolving earth carries any particular region of the atmosphere into the night, when the ionising radiation is cut off, the ions re-combine, and most rapidly at the lower surface, which in the course of a few hours moves upward from a level of about 50 km. to 100 km. or more. The conductivity of the ionised layer is consequently diminished at night, by the reduction in both the thickness and the specific conductivity; this affects the electric currents flowing in the ionised layer, to which the daily magnetic variations are due The latter are much more intense by day than by night, and in low latitudes (where the sun's rays are most direct) than in regions farther from the equator. The magnetic variations also show clearly that the conductivity of the layer ionised in this way is distinctly greater (by at least 25 per cent.) at sunspot maximum than at sunspot minimum; this requires a change of intensity in the ultra-violet radiation by about 60 per cent., which is remarkable in view of the absence of any comparable variation, during the sunspot cycle, in the sun's visible radiation. The increase in the ultra-violet radiation seems to be due to enhanced emission from the sun's surface as a whole, and to be independent of particular disturbed localities on the sun.

The other solar ionising agent is corpuscular, and proceeds from locally disturbed areas on the sun's surface, often, though not always, associated with visible markings such as sunspots. The corpuscles are ejected in laterally limited streams, the direction of which varies as the sun rotates. When such a stream happens to impinge on the earth, the air becomes highly ionised in the atmospheric regions affected, which are situated geographically within about 20° of the poles of the axis of magnetisation of the earth, though they spread farther towards the equator when the streams are specially intense. The corpuscles can penetrate the earth's atmosphere down to not less than 80 km. above the ground; they impinge not only on the side of the earth facing the sun, but also bend round to the right side of the earth, where they produce visible auroræ. The deflexion of the corpuscles towards the magnetic poles is due to the earth's magnetic field, and indicates that the streams have a slight excess charge and are ionised.

The ionisation of the auroral zones renders these regions of the atmosphere highly conducting, and permits intense electric currents to flow in them; the changing magnetic field of these currents is observed as a magnetic storm (or lesser disturbance). Even if auroræ were not visible, the magnetic observations would indicate the existence of highly conducting upper air in polar regions.

The ionisation of the air due to the solar corpuscles is much less uniformly distributed than the ionisation over the sunlit hemisphere due to ultra-violet radiation; the limited distribution of bright auroræ gives visible indication of this. Also the ionisation by corpuscles varies irregularly with time, and cannot be predicted at present with any certainty; it depends both on the activity and presentation (towards the earth) of the disturbed solar areas. If such an area remains active after the lapse of a solar rotation period (about 27 days), it may affect the earth a second time, or even several times after successive rotations. Hence arises the clearly marked tendency for magnetic disturbance to recur after 27 days; but this is only a tendency, for the direction of the stream from a solar disturbed area may change, or the area may not remain long active.

The influence upon wireless transmission of the regular change of ionisation from day to night has long been recognised; the improved conditions at night, especially for long waves, are naturally accounted for by the withdrawal of the refracting ionised layer to greater heights at night, where the ions have longer free paths and where their less frequent collisions dissipate less of the energy acquired from the electric waves. The influence upon wireless of the less regularly distributed but occasionally very intense ionisation due to solar corpuscles has only lately become reasonably certain. The effects are likely to be complicated, and it will doubtless be a long time before they are clearly ascertained. An interesting feature suggested by recent observations is that transmission from Europe to America is more affected than that from Europe to the East. This is not unexpected, in view of the inclination of the earth's magnetic to its geographical axis; the centre of the north auroral zone is about 10° from the geographical north pole, in the direction of Canada, and auroræ are observed in Canada in much lower latitudes than in Europe. The region of abnormal corpuscular ionisation will therefore extend about 20° farther towards the equator in Canada than in Russia.

The Decimal Classification of Melvil Dewey and its Extension by the Brussels Institute of Bibliography.

By Dr. S. C. Bradford, The Science Library, S.W.7.

The study of classification is a necessary preliminary to the preparation of a comprehensive guide to recorded information. Of the multifarious systems that have been suggested for the classification of literature, Dewey's "Decimal Classification and Relative Index," first developed in 1873, seemed the most hopeful of any produced hitherto, and was hailed with jubilation in many quarters. But, although it proved successful for the purpose for which, in the first place, it was designed, *i.e.* the classification of books, it has been found inadequate when applied to greater bibliographical detail, such as individual scientific and technical papers. In its original form it is therefore unsuitable for the preparation of a detailed index to the records of human work and thought.

Dewey's scheme comprises two parts: a classification in which more or less logically arranged subdivisions of knowledge are given separate arbitrary numbers, and an alphabetical index of subjects, regarded by Dewey as the more important feature of the system, to indicate the respective numbers of the subdivisions. The index aims at giving similar or synonymous words and the same words in different connexions, so that any person of intelligence can scarcely fail to get the right number. In this scheme the whole of knowledge is represented by unity, and divided into ten main divisions. The first, comprising all numbers between 0·0 and 0·1, is assigned to works dealing with general subjects such as encyclopædias, bibliographies, etc., and those that cannot be allocated to the nine more definite subdivisions that follow. These are:

0·1 Philosophy.	0·6 Applied Science.
0·2 Religion.	0·7 Fine Arts.
0·3 Social Sciences, Law.	0·8 Literature.
0·4 Philology, Languages.	0·9 History, Geography, Biography.
0·5 Pure Science.	

Each of these main groups is again subdivided by addition of another decimal place, and further subdivision of these secondary and succeeding groups is obtained as desired. Thus:

0·5 Pure Science.	0·5315 Gravity, Ballistics.
0·53 Physics.	0·53157 Internal Ballistics and the Energy of Projectiles.
0·531 Mechanics.	

In practice the initial decimal point is omitted, and others may be intercalated to assist the memory or aid the eye. Thus catalogue titles, or abstracts, of books, pamphlets, monographs, papers, notes, etc., dealing with internal ballistics, are to be mounted on cards of uniform size and filed under the number 531·57; and no matter by what bibliographical agency the information is indexed, all the index cards relating to this subject fall together automatically. The student who requires to know what has been recorded on this subject, having ascertained the number from the alphabetical index to the subject-classification, can, by looking at the cards bearing this number, gain access immediately to all the information desired that has been rendered available.

The advantages of this system are: (1) Its simplicity: the order of filing is merely that of the decimal numbers, so that sorting of cards is mechanical; (2) each subject is represented by a single decimal number occupying a definite position in numerical sequence and independent of the language in which the conception is expressed; (3) nine further subdivisions can be obtained as desired by addition of one more figure, and these new subdivisions can be inserted between two previously established divisions without disturbing their numerical order; and (4) the number representing a given conception can be ascertained from the alphabetical index without consulting the classification.

Dewey's classification contains also the germ of an idea which, developed afterwards by the Brussels Institute, converted his classification into a powerful instrument of bibliography. There are certain general groups into which bibliographical material may be divided that are independent of subject, or common to a large number of conceptions. Thus, at the head of each of the main subdivisions (*e.g.* of 5, Pure Science), there is a section

01 Philosophy, Theories.
02 Compends, Text-books.
03 Dictionaries, Encyclopædias.
04 Essays, Lectures, Addresses.
05 Periodicals.
06 Societies, Transactions.
07 Education, Methods of Teaching.
08 Collected Works.
09 History.

Such subdivisions relate to the form or purpose of the work. For example, the *Proceedings* of the Physical Society would be numbered 53·06. Again under geology, 55, there is a section, 554 to 559, to be subdivided by countries like geography, 94 to 99. Altogether, a good many examples occur of the application of such an idea, but the classification, as published, was suitable for the purpose of arranging the books in the New York State Library, and the principle of common subdivisions was not developed in detail. If a universal guide to knowledge should be organised on the basis of the Decimal Classification, mankind will owe much to Melvil Dewey, and it is not the less to his credit that the original scheme proves inadequate when applied, as Dewey hoped, to the indexing of scientific papers as a whole.

However, the classification of separate articles requires much more subdivision than the grouping of works even on the largest scale. The main subject-classification itself requires to be more detailed, and when this has been developed as much as possible, there remain the various common aspects of a given subject to be dealt with. As an example, the number 661·25, in the extended classification, represents the sulphuric acid industry; and this requires to be further subdivided according to the process of manufacture. When this has been done, we have yet to provide for a variety of considerations that may apply to the number 661·25 or to its subdivisions. For example, there will be papers on theoretical or experimental studies relating to the manufacturing process, at the start, while in use, or after modification; papers from the point of view of realisation of the manufacture, such as gathering materials, special operations, raw materials, accessory products, machines employed, fixed machinery, engines, machine tools, implements, results obtained, by-products, fittings and apparatus; papers from the economic point of view, such as cost of materials, labour, selling price; and from the point of view of premises, sites, and personnel of various kinds.

These and other general points of view are common to the various branches of the sulphuric acid industry, as well as to a vast number of specific subject-divisions. Again, it will be necessary, in many cases, to classify bibliographical material according to place, time, or language, or, it may be, according to the form of the work. Thus, sulphuric acid manufacture may need to be treated from the point of view of country, or period, or it may be desired to distinguish between large treatises, manuals, books of tables, popular descriptions, collected papers or historical studies.

Now although, as it has been stated, Dewey's classification contains the germ of an extension by common subdivisions, this was not developed, and his tables have no places for grouping material by common headings such as have been mentioned. Indeed, to provide for such subdivision as necessary in each case, without perfecting a system of general classes, would have increased the size of the classification to several hundred volumes. For this reason his scheme in its original form is hopelessly unsuitable for the preparation of a comprehensive index to knowledge, and appears never to have been used for bibliographical work on a large scale.

This was the state of affairs when, in 1895, the first International Conference on Bibliography was held in Brussels. The Conference had to search in a spirit of impartiality for the principles on which could be established a universal bibliographical classification. It decided that the Dewey system was based on such principles and was capable of being transformed into a highly satisfactory classification. As a result of the Conference, the Institut International de Bibliographie was founded, which undertook the work of perfecting the Dewey code.

The classification itself was considerably extended, and, in addition, the conception of auxiliary tables for common subdivisions was developed. These are of two kinds: (1) Analytical subdivisions that relate to special subjects only, and (2) common subdivisions that may be added to any item of the classification. For example, general operations in photography are made into a group of special analytical subdivisions that are available for arranging matter relating to any of the various photographic processes. The numbers representing such subdivisions are preceded by a zero. For example, toning is one such division, represented by 0235, and this number can be added to any of the numbers representing a photographic process—thus 77·21 denotes silver processes in general, and 77·21·0235 means toning in relation to processes based on the use of silver salts.

Besides these special subdivisions that relate to particular parts of the classification, there are five tables of common subdivisions that may be used in any connexion. The first relates to the form of the publication, and is developed from the general subdivisions of the Dewey scheme described above, the numbers being enclosed in parentheses. Thus (05) represents a periodical, so that a magazine restricted to acetylene welding, for example, can be indicated by adding (05) to the number for that process as 665·882(05). Table II. comprises the geographical subdivisions. These are also enclosed in parentheses. Thus (493) denotes Belgium. Consequently sulphuric acid manufacture in Belgium would be 661·25(493). Table III. has subdivisions by language and Table IV. by time. The fifth of these common groups includes all subdivisions corresponding to general points of view. These are indicated by numbers commencing with a double zero; *e.g.* 00311 represents net cost of the raw materials. If it is desired to classify a paper on that aspect of the sulphuric acid industry, it would be numbered 661·25·00311; and these ten figures represent an idea requiring eleven words to express it in English.

By such a logical extension of Melvil Dewey's scheme it was converted into a beautiful bibliographical tool of the greatest power that is suitable for work of the finest detail; and in order that the classification may be kept up-to-date, a Commission was established to issue additions as needed. From time to time, with the progress of science and invention, new divisions become necessary and are published by the Commission. Or, an expert who discovers the need may suggest a considered extension of the scheme, and if this is drawn up in accordance with the principles of the classification, it will be incorporated.

Obituary.

Prof. E. H. Rennie.

Time irresistibly takes its terrible toll and the names left upon the roll of our old guard are now very few. The Australian mail just in brings me a copy of the Adelaide *Register* of Jan. 10, with an account of the sudden death of my old friend, Prof. Edward H. Rennie. He seemed to be in good health but on Saturday, Jan. 8, going into the garden, he took a drink of water, lay down—and just died. A few days previously, I had received a long chatty letter from him, dated Dec. 20. In this he speaks of having had a very strenuous year and feeling somewhat played out. During the first six months, he had been acting vice-chancellor of the University; then came the University jubilee and after this the meeting at Perth, of the Australasian Association for the Advancement of Science, of which he was president. Added to this, he had much anxiety on account of the illness of his wife and daughter. He tells me of the journey across the arid region to Perth, lasting three days. At one part, the railway runs in an undeviating straight line, nearly 400 miles, across flat desert, where nothing was growing, he says, over about 2 feet high, the horizon being unbroken by a single tree or elevation of any kind. People seldom realise how much of Australia is country of this order. "Aboriginals were seen here and there almost in their primitive condition, except that they wore clothes."

Rennie's first communication to the Chemical Society was made with Alder Wright. He then worked with me at the London Institution. The record of our work appeared only in the *Chemical News*. I was greatly attracted to him and was hoping to secure him as my chief assistant at the Finsbury Technical College, at the opening in 1883, but a more tempting offer came from home and he returned to Australia in 1882. Two years later, he became professor in Adelaide University. I visited him in 1914, reaching Adelaide a week ahead of the Association, in order to stay quietly with him. I then gained some idea of the man's devotion to his post and the great burden of work upon his shoulders. Rennie's services to his University as a teacher cannot be over-rated. He was extraordinarily thorough, deliberate and exact in his outlook and work, a most painstaking teacher. His scientific services to Australia are also to be ranked very high, though unfortunately, owing to the calls upon him as teacher and administrator, he had but little spare time for original inquiry. He devoted himself particularly to the study of native materials. Perhaps his most interesting discovery was that of trihydroxymethylnaphthaquinone in *Drosera Whittakeri*.

Australia is remarkable for its numerous species of long trailing Drosera. Rennie and I spent a delightful day in the hills behind Adelaide and nothing interested me more, in my journey around the continent, than his digging up the Drosera tubers and showing me the beautiful glistening crystals of the hydroxyquinone present in the outer layers. Why or wherefore such a compound should so come to the surface in a plant is difficult to say.

We spent another day on the seashore tracking down *Lotus australis*, which I was anxious to compare with our *corniculatus*. We found it in quantity, highly cyanophoric, very like the dwarf plant growing at Ballantrae in the sandhills. I fancy *corniculatus* must have wandered to the Antipodes and changed its name.

Australians are in no way sufficiently alive to the need of studying their natural organic products. The wonderful work on eucalyptus oils done by Smith and Baker of Sydney has not yet been appreciated. Only recently (Feb. 12), an advertisement was printed in Nature for a lecturer and demonstrator in organic chemistry, at the University of Sydney, salary £350 per annum. Only by accident is a chemist good enough for such a post likely to be bought at so low a price, perhaps that of a dock labourer—what Billy Merson earns in a week. No one there will rate a man very high who is paid such a salary. It were time that organic chemical science were put upon a higher footing, especially in so important a seat of higher learning as Sydney—so that it may have some chance of being mentioned along with the harbour.

Australia can ill afford to lose a man of Rennie's calibre and will do well to take warning and relieve them more of ordinary routine labours, if she find other such men to serve her.

Henry E. Armstrong.

Mr. A. B. Lee.

Arthur Bolles Lee, who died on Mar. 3 at Clarens, Switzerland, was born at Froyle, Hampshire, in 1849. He spent most of his life in Switzerland, and hence, though well known by name, was scarcely known personally in Great Britain. He was for several years an assistant under Prof. Korotneff in the Russian Marine Laboratory at Villefranche.

Mr. Lee was the author of a number of papers chiefly on oogenesis, spermatogenesis, and other cytological subjects, published from 1884 onwards, the last of which appeared in December 1924. But he was best known as the author of "The Microtomist's Vade-Mecum: a Handbook of the Methods of Microscopic Anatomy," first published in 1885. This work contained an account of all the methods that had, up to that time, been recommended for the preparation of microscopic objects whether as whole mounts or in section, and it became at once the standard work of reference on the subject. In the subsequent editions Mr. Lee judiciously discarded many of the older and less satisfactory methods as he added careful accounts of new processes, so that the "Vade-Mecum" was always a helpful guide to what had been proved best in methods of fixation, clearing, imbedding, section-cutting, staining and mounting of organisms and of tissues. Seven editions of this work in English up to 1913, at least two in French (by Lee and Henneguy) and four in German (by Lee and Mayer) afford evidence of the value and usefulness of this manual, which, indeed, formed part of the essential equipment of a zoological laboratory, where it was the source of reference on all matters of technique for senior students and for investigators. The last English edition (1921)—the eighth—was edited by Dr. J. B. Gatenby, but, as he stated in his preface, the bulk of the volume was still largely the work of Mr. Lee.

In recognition of his services to microscopical science, Mr. Lee was elected an honorary fellow of the Royal Microscopical Society. He leaves a daughter and two sons, one of the latter, Dr. G. W. Lee, being one of the Senior Geologists in the Scottish office of the Geological Survey of Great Britain.

A veteran botanist of striking personality, Prof. Ludwig Radlkofer, has recently been removed by death in his ninety-eighth year, on Feb. 16 last. He was born in Munich on Dec. 19, 1829, took the degree of M.D. at that University in 1854, of Ph.D. at Jena the following year, and in 1863 became professor of botany in his native city. He began his career as an author in 1855, soon being attracted to the Sapindaceæ, especially the genus Serjania, which he monographed in 1875, returning to it more than once, and continuing to write even so late as the last few months. He received many distinctions abroad, and was elected a foreign member of the Linnean Society of London in 1897. He claimed to have been the first to introduce the anatomical method in academical teaching, and was very anxious that his pupil, Dr. Hans Solereder (1860–1920), should be permitted to examine the Linnean herbarium and also the older plant collections in the British Museum such as the Clifford and Sloane herbaria. He introduced the topic at the Norwich meeting of the British Association in 1868 by his paper "On the Structural Peculiarities of Certain Sapindaceous Plants," and again in 1885 at Aberdeen "On the Application of the Anatomical Method to the Determination of the Linnean and other Herbaria." Needless to say, this proposal that every specimen should be so examined could not be entertained, as it involved the practical destruction of the types destined for the information of later generations of botanists.

B. D. J.

We regret to announce the following deaths:

Prof. D. Berthelot, professor of physics in the University of Paris (Faculty of Pharmacy) and *membre titulaire* for the section of general physics of the Paris Academy of Sciences, aged sixty-two years.

Kommandør C. F. Drechsel, General Secretary of the International Council for the Exploration of the Sea, at Copenhagen on Mar. 2, aged seventy-three years.

Prof. Carl Runge, professor of applied mathematics in the University of Göttingen, distinguished for his work as a mathematician and spectroscopist, early in January, aged seventy years.

Prof. A. W. Scott, for fifty-five years Phillips professor of science at St. David's College, Lampeter, on Mar. 7, aged eighty-one years.

Prof. Yovan Tsvyitch (Cvijić), of the University of Belgrade, president of the Yugoslav Academy of Science and an honorary corresponding member of the Royal Geographical Society, who was well known for his geographical, geological, and ethnographical studies, on Jan. 16, aged sixty-one years.

Dr. A. E. Verrill, from 1864 until 1907 professor of zoology at Yale University, and emeritus professor since 1907, who worked chiefly on marine invertebrates, aged eighty-seven years.

News and Views.

The new Sir William Dunn School of Pathology was formally opened at Oxford on the afternoon of Friday, Mar. 11. Unfortunately the Chancellor of the University, Viscount Cave, who was to have performed the opening ceremony, was prevented by illness from being present. The circumstances which led the Sir William Dunn trustees to make this magnificent presentation to Oxford were detailed by Mr. C. D. Seligman, the senior trustee present, and the building was gratefully received and declared open by the Vice-Chancellor, the Warden of All Souls, on behalf of the University. The objects of this munificent offer made to the University in Nov. 1922, subject to confirmation by an Order in the Court of Chancery of Feb. 1924, have thus been carried out. Of the total gift of £100,000, £80,000 has been devoted to the building and to its equipment, and £20,000 has been invested as a fund for maintenance and for the encouragement of the study of pathology. On the other hand, the University has provided a site of 2¼ acres near the south-east corner of the University Parks, and covenants to make permanent provision for the upkeep of a chair of pathology and for a full teaching staff. £3000 has, moreover, been allocated for the refitting of Prof. Dreyer's old Department of Pathology as a school of pharmacology—a subject which hitherto was poorly housed in attics under the roof of the old Radcliffe Library in the Museum.

The building which students of pathology in Oxford have now for their use is of red brick with stone coins, and is in three storeys in a simple and pleasing style of architecture, well lit by large windows. The main entrance leads up to the first floor, where are the lecture-room, museum, library, chemical laboratories and culture rooms. The large students' laboratory, and numerous research rooms are on the upper floor, while the service rooms, the refrigerating plant and cold chamber, centrifuge room, low-pressure apparatus room, engineering work-shop, store rooms, etc., are in the basement, whence a covered way leads to the animal house, an important two-storey building where there is accommodation for the live-stock and a caretaker. The requirements of any modern building for biological research are now of so varied a character that a gift for planning of a high order is needed to provide all needful accessories in suitable juxtaposition, and Prof. Georges Dreyer is much to be congratulated upon his great and obvious success in this matter. He now controls the finest scientific building in Oxford. The following inscription is placed on the main staircase:

> *Hoc aedificium A.S. MCMXXVI completum*
> *suppeditavit Gulielmi Dunn Baronetti*
> *munificentia pecuniis ingentibus ad levandos*
> *humani corporis dolores testamento devotis.*

In a paper read to the Institution of Electrical Engineers on Mar. 3, Commander H. T. Harrison discussed the problem of public lighting by electricity. He pointed out that, since the War, practically no advance in public lighting has been made in Great Britain. In America, on the other hand, good progress is being made in this direction. The town of Indianapolis, for example, installed a system of public lighting ten years ago. It has now completely scrapped the system, with the result that the illumination has been doubled with very little increase in the annual cost. The reason given for the change was that the great increase in automobile traffic made it necessary. Commander Harrison, who is responsible for many public lighting schemes, favours centrally suspended light sources for most business thoroughfares. In streets with buildings on either side, the span wires can be fixed to the buildings; in other cases they can be attached to steel columns set well back from the road so as not to offer obstruction to the traffic. He said that in shopping districts, where improved lighting benefits trade, it is easy to get permission to fix the span wires to privately owned buildings. If high-powered gas-filled lamps were used they would only want renewing about three times a year. Access to the lamps could be obtained by electrically propelled and operated tower wagons. Heavy batteries at the base would provide the necessary power and ensure stability.

Whilst we admit, with Commander Harrison, that economies could be effected in this way with improved lighting, we think that many will be opposed to span wires. It is true that the main streets of the city of London are lit in this way, but we think that the unnecessary multiplication of overhead wires is to be deprecated. In a gale of wind it is noticeable that the movements of the shadows produced by the vibrations of the lamps are objectionable. For lighting high roads and arterial roads passing through populated districts and used by motor traffic, Commander Harrison proposes that concentrated light sources at a considerable height above the ground should be used. In our opinion, such a solution would make special additional lighting arrangements necessary in foggy weather. Some of the lighting problems discussed, for example the relative advantages of having lights in the centre of the road or at the side where the reflecting power of buildings must be taken into account, will be of value in the theory of photometry.

Sir Flinders Petrie's preliminary report on the work of the School of Archæology in Egypt, which, owing to the conditions imposed on archæologists in Egypt, is now engaged in investigating the Egyptian remains on the Palestinean side of the frontier, describes the infertile conditions which have prevailed on the frontier during the current winter. These, however, have provided a more plentiful supply of labour than is normal, and have in this way been propitious for the initial year of the School's work in the area. The fortifications of Gaza have been examined, and a fourteenth-century B.C. wall revealed, of which the lower construction may be of Canaanitish age. The present state of desolation of much of the built-over area seems to offer a favourable opportunity for excavation, but much Roman material would have to be moved. In Sir Flinders Petrie's opinion, the site most likely to be profitable in historical results is that of Tell-Jemmeh, a mound about nine miles south of Gaza. The city was important in Hyksos times and flourished until about 1000 B.C., accumulating about 50 ft. depth of buildings. It was afterwards burnt and refortified, but its life ended about 500 B.C. A ruin in the neighbourhood named Umm Jerrar was supposed to be the Gerar of Abraham and Isaac, but this name probably belongs to the Tell. Gerar was of importance under the Philistine king Abimelech, but only appears once later under Asa in 940 B.C. During this season it is proposed to search thoroughly a fort with the surrounding buildings on the more prominent end of the Tell.

PROF. A. S. EDDINGTON, in his ninth Gifford Lecture in the University of Edinburgh on Friday, Mar. 11, reminded his audience that the typical laws of physics are not controlling laws; they are identities implied in the structure of the cycles of entities to which they refer. The controlling laws (if any) in the basal material are of a type which has not yet come within our knowledge. The physical universe cannot be completely subject to deterministic law unless mental states are also subject; it was for that reason that Prof. Eddington emphasised in an earlier lecture that through the new quantum theory physics is no longer pledged to a deterministic system—so that the nature of the governing laws of the mental substratum may be left open. After all, we have intimate acquaintance with a part of this substratum in our own minds. Prof. Eddington thinks that the hypothesis that this procedure is expressible by mathematical equations is scarcely plausible. We are disinclined to make this philosophical outlook too definite because we do not yet know how to place the physical laws of atomicity and quanta. The quantum theory is developing along rational lines, and this seems to suggest that the laws of atomicity will ultimately be assimiliated with the field laws by some profound extension of the idea of physical cycles. But the opposite view that whereas all other physical properties are due to our mental selection in world-building, the integral character of atoms and quanta is inherent in the basal world-stuff, is attractive. It reminds one of Kronecker's famous saying in pure mathematics—"God made the integers; all else is the work of man."

THE Friday evening discourse at the Royal Institution on Mar. 11 was delivered by Sir George Macdonald on "The Wall of Hadrian." Hadrian's Wall consists of the stone wall itself, the ditch in front, the series of forts, mile-castles and turrets which housed its defenders, and the earth-work in its rear known as the Vallum. Excavation has shown that the earth-work is certainly not older, and probably rather later, than the forts, and was not a military work but a civil or legal boundary. The forts, again, or at least some of them, have been definitely proved to be earlier than the stone wall. Thus we seem to get the chronological sequence—isolated forts, Vallum, stone wall. The evidence of pottery and coins suggests unmistakably that there was extensive destruction and restoration about A.D. 180, events that are certainly to be associated with the great rising in which southern Scotland was lost. The barrier was again swept about A.D. 270, and yet once more about A.D. 330. The final abandonment came about half a century later. In 1895, Prof. Haverfield and his colleagues of the Cumberland Excavation Committee discovered at Appletree a long stretch of wall built of turf, abutting at either end on the Wall proper, with which it did not seem otherwise to be organically connected. At first it looked as if the turf wall were going to provide a new and unexpected way of reconciling the rival claims of Hadrian and Severus, but in 1925 it (or another turf wall) was found six or seven miles farther east at Aesica, this time on the north of the stone wall and ultimately beneath it. Until further digging has taken place, it is unwise to theorise further. The key will probably be found at Birdoswald.

A PAPER read by Mr. H. N. Green at a recent meeting of the Illuminating Engineering Society dealt with a subject of great scientific interest, on which little is generally known—the use of artificial light in connexion with aerial navigation. Much care is now expended on the marking out of air-ways by beacons and the illumination of aerodromes to facilitate safe landing by night. The summit of a hill is not always the best site for a beacon. Hills are apt to be capped with clouds. It appears better to select a site slightly above the level of surrounding country and mount the beacon on a tower high enough to clear ground mists. Distinctiveness is usually given to beacons by flashing, the optical system rotating as a whole. But recently neon gas beacons, on account of the unmistakable colour of the light (red-orange) and the rapidity with which such lights can be flashed, have come into favour. It is even stated that the neon beacon at Croydon aerodrome can be seen in clear weather by pilots leaving the French coast. Effective methods of 'floodlighting' landing areas have now been introduced, and by means of lights sunk in the ground, pilots can be informed of the intensity and direction of the wind. The greatest difficulty is fog. Regular flying is not yet attempted at times when the visibility is very low. But pilots are liable to be caught in a mist, and in such circumstances can receive effective aid by means of directional radio, and the 'leader cable,' which carries a low frequency alternating current, and traces the correct route into the aerodrome. Once this cable has been picked up by the instruments on the aeroplane, the pilot can steer his way to the landing ground, where special lights assist his descent.

PART 12 of Volume 3 of the *Rendiconti della Reale Accademia Nazionale dei Lincei*, which has recently been issued, contains an account of the meeting of the Academy held on June 5, 1926, in the presence of the King and Queen of Italy. In his opening speech the president, Prof. Scialoja, referred briefly to the activities of the previous session. The library has been extended by the addition of premises adjacent to the Palazzo Corsini and should now meet the needs of the Academy for many years to come. The Copernican Museum, which was presented to Italy some years ago by the Pole, Wolinsky, and includes valuable records of the distinguished astronomer, together with old astronomical instruments and terrestrial and celestial globes, has been transferred from the Collegio Romano to a more fitting setting in the premises of the Academy. Among the donations announced were: the sum of 100,000 lire, given by the Bank of Italy, the Bank of Naples, and the Bank of Sicily, to celebrate the completion of the twenty-fifth year of the King's reign, to be awarded as a single prize for a thesis on the economic, financial, and social consequences of the European War; an equal amount, given by the Italian Banking Association, to provide a biennial prize; a similar sum, presented by the Assurance Company of Milan, on the occasion of its centenary, for the purpose of making a biennial award for scientific work bearing on insurance; 35,000 lire from the Italian Institute of Social Hygiene, to create two awards for investigations on the pathology of cancer and for work on social hygiene, and to furnish two gold medals to be given for work on social hygiene and industrial hygiene respectively; the sum of 125,000 lire, collected by public subscription in honour of Battista Grassi and presented by him to the Academy, to found an annual award for investigations on parasitology.

In the succeeding discourse, dealing with the conceptions of the atom and molecule due to Avogadro and Cannizzaro, Prof. Nasini protested against the opinion that, in the light of recent developments, the old fractional atomic weights correspond with mixtures similar to that present in sea-water and must be regarded as deposed. Prof. Nasini discussed the so-called 'Avogadro number' and is unwilling to consent to this magnitude being known as the 'Loschmidt number.' This name may justly be given to the number of molecules in unit volume of a gas for which Loschmidt was the first to determine an approximate value; the name 'Avogadro number' should, however, be retained for the number of molecules in the gram-molecular weight of any substance, this being a universal constant derived directly from Avogadro's law. Furthermore, although the ultimate particles of matter are now known to be the electrons and protons, and not the atoms, Cannizzaro made the definite statement that extension of the means of analysis available in his day might lead to further division of the atom of hydrogen, and later (1874) asserted that the atom contains parts capable of relative motion. The bearings on this question of the transformations of radioactive elements, of isotopes, and of the periodic law were also discussed.

The March issue of the *Nineteenth Century* contains an interesting article by Mr. Edwin Edser entitled "Science and Wonderland." Mr. Edser's thesis is that physical science has left the broad highway of logic and consistency and strayed into meadows where all is new, surprising, and paradoxical—the wonderland to which his title refers. While practically all men of science must agree that the present position, with its coexistence of wave theory and quantum theory, and the difficult physical implications of the generalised theory of relativity, is full of paradoxes and trouble, it is open to question whether Mr. Edser's presentation preserves due proportion, and whether his particular criticisms are really cogent. He urges that an ether must exist by means of such arguments as, "If light is propagated through space in the form of waves, the space must be occupied by a medium which can propagate the waves. To speak of the propagation of waves in an empty space is as meaningless as to discuss the propagation of the human race in an uninhabited country."

The real question, however, is not whether we use the term 'ether' or not, which is a question of words, but what meaning and properties we are to attribute to the ether. Einstein himself is quite ready to call empty space in which gravitational and electromagnetic fields prevail the 'ether,' but the properties of this ether are not the traditional mechanical properties which it was formerly sought to attribute to it. Mr. Edser's discussion of the theory of relativity, to which much of the article is devoted, gives a comparatively long account of the Michelson-Morley experiment. No distinction, however, is made between the special and the generalised theory, which are not even mentioned separately by name, while it is definitely suggested that the influence of gravitation on light was predicted by Einstein on the basis of a corpuscular theory. Again, the discussion of the quantum theory of spectra is not very satisfactory, for the statement that in the atom "only those orbits are possible in which the kinetic energy is equal to an integral number of quanta," scarcely represents the essence of Bohr's theory, as usually understood. There is no reference to the new quantum mechanics of Heisenberg and his followers, the general trend of which can be put quite simply.

The inclusion of Boyle's experimental notes on the mechanical origin of electricity and the mechanical production of magnetism in the "Old Ashmolean Reprints" being issued by Dr. R. T. Gunther (Magdalen College, Oxford. 3s.) was a happy thought. The notes give a clear account of the experimental knowledge and the orthodox theories of the subject current in 1675. We read how, when amber is rubbed or heated, it emits rays or "files of unctuous steams," which, when they become a little cooled by the external air, shrink back to the amber and carry with them any light bodies in the neighbourhood. Boyle points out how odoriferous gums and perfumes send forth fragrant steams when heated. Apparently navigators and others of that period were willing to pay the owner of a good lodestone to have their needles, swords, knives, etc., magnetised. It is also interesting to read how a bar of steel placed vertically acquires a temporary 'verticity' (polarity), and how when its direction is reversed the polarity is often reversed also. This was one of the experiments

Lord Kelvin used to show in his lectures on magnetism to students. He demonstrated also, like Boyle, how unstable was the induced magnetism.

DR. GEORGES SCHREIBER in an article in *The World's Health* for February discusses the important question, "Should a medical examination before marriage be obligatory ?" In a few of the United States a pre-nuptial certificate is necessary as regards the absence of venereal diseases, and in some States, in addition, absence of tuberculosis, epilepsy, and alcoholism. While generally restricted to the male, in two States the woman must also present a certificate. In other States a declaration on oath without medical examination is required. In the Netherlands, France, Germany, and Austria, pre-nuptial medical examinations are advocated by the health authorities, but there is no compulsion. In Scandinavia the registration by a doctor of a declaration on oath by the contracting parties as to their state of health is required. Dr. Schreiber considers that there are many objections to a compulsory pre-nuptial medical examination, and that the Scandinavian system seems to provide the most equitable, the most efficacious, and simplest safeguard.

AT a recent meeting of the Zoological Society of London, Lord Rothschild exhibited a mounted specimen of *Varanus komodensis*, the 'Dragon' of Komodo Island, Dutch East Indies. Specimens of other species were also shown for comparison. Much has been written lately about this, the largest of the lizards, but most of the statements are much exaggerated. The type-specimen is 12 feet 4 inches in length. None now alive on the island exceeds 10 feet in length, but their bulk is very considerable. The interesting feature of the Komodo monitor, apart from its bulk, lies in its relationship. The twenty-two other Indo-Australian species all have smooth scales, with one exception, tails much longer than the body, and narrow heads; *V. komodensis*, on the other hand, has the scales much raised with a central keel, a comparatively short tail, and a broad blunt head; in these respects it resembles the much smaller West African lace-lizard *V. albigularis.* The only Indo-Australian Varanus showing raised scales, and these on the hind neck only, is *V. rugicollis* of Borneo, but this is a small slender species. *V. salvator* of western Malayasia and *V. giganteus* of New Guinea come near to *V. komodensis* in length, examples nearly reaching 8 feet being on record; but neither ever approaches this species in bulk, a 10-foot specimen of which weighed 3 cwt. alive.

THE Ural region has a special interest for archæologists, lying as it does on the route of migrations of prehistoric races between European Russia and Siberia. During the bronze age the region was one of the main centres of mining industry, as is evidenced by numerous remains of primitive mines. A still earlier period left its traces in various sites of palæolithic culture. But most interesting of all are numerous finds of wooden objects like boats, figures of gods, etc., which occur in the pith-deposits near the main ridge of the Ural mountains; these remains are similar to those found on the sites of ancient lake settlements on piles in Switzerland. No systematic investigations have been so far undertaken in the Ural region, but the Russian Academy of Sciences is organising a special expedition there in 1927.

THE Council of the British Association has nominated Sir William Bragg as president of the Association for the meeting in Glasgow in 1928. Rapid progress is being made with the arrangements for the forthcoming meeting in Leeds this summer, under the presidency of Sir Arthur Keith, and it is expected that a preliminary programme will be issued in April.

DR. HAROLD JEFFREYS has been awarded the Adams Prize for the period 1925-26 for an essay on "The Constitution of the Interior of the Earth, and the Propagation of Waves through the Interior and over the Surface of the Earth." The prize is awarded by the University of Cambridge every two years for an essay on some branch of pure mathematics, astronomy, or other branch of natural philosophy, and is of the value of about £250.

THE executive committee appointed to make arrangements for an International Botanical Congress in England in 1930 has decided that the Congress shall be held in Cambridge, commencing about the middle of August. The following officers have been appointed: *Chairman of the Executive Committee*: Prof. A. C. Seward; *Treasurer*: Dr. A. B. Rendle; *Secretaries*: Mr. F. T. Brooks and Dr. T. F. Chipp.

IN a letter to the editor, Mr. A. G. Tarrant refers to the sympathetic attitude displayed in the leading article in NATURE of Mar. 5 towards the appeal which is being circulated by the National Union of Scientific Workers. He raises the problem of the unqualified practitioner in science, and states that unless a definite assurance is given by the executive of the Union that it does not include any such workers in its membership, it will meet with opposition from members of such bodies as the Institute of Chemistry and the Institute of Physics. We have communicated with the general secretary of the Union, who informs us that it is definitely stated in the rules that one of the objects is "to insist on a legally recognised qualification for all scientists engaged in the practice of science for remuneration," and that "only those who possess a recognised degree in science, mathematics, or technology, or other qualification recognised as equivalent thereto," are entitled to the privileges of membership.

AT the annual general meeting of the Society of Public Analysts, held on Mar. 2, the following officers were elected: *President*: Mr. E. Richards Bolton; *Vice-Presidents*: Mr. R. L. Collett, Mr. C. H. Cribb, Mr. John White; *Hon. Treasurer*: Mr. Edward Hinks; *Hon. Secretary*: Mr. F. W. F. Arnaud.

MR. A. E. MOURANT, Department of Geology, University Museum, Oxford, writes asking for reports of the earthquake which affected lands bordering the English Channel shortly before 11.30 P.M. on Feb. 17:

Further information regarding the shock of July 30 last would also be welcome (see Nature, Aug. 7, 1926, p. 204).

Applications are invited for the following appointments, on or before the dates mentioned :—A pathologist at the Charing Cross Hospital Institute of Pathology—The Secretary, Charing Cross Hospital Institute of Pathology, 62 Chandos Street, W.C.2 (Mar. 23). A junior scientific assistant for Admiralty research—The Secretary of the Admiralty (C.E. Branch), Admiralty, Whitehall, S.W.1 (Mar. 26). Two junior technical officers in an Admiralty Experimental Establishment—The Secretary of the Admiralty (C.E. Branch), Admiralty, Whitehall, S.W.1 (Mar. 26). An assistant in the Liverpool Observatory, Bidston—The Mersey Docks and Harbour Board, Liverpool (Mar. 31). Six forest officers for service under the Government of Burma—The Secretary to the High Commissioner for India, 42 Grosvenor Gardens, S.W.1 (April 1). A scientific officer under the directorate of scientific research, Air Ministry, primarily for research in connexion with electrical ignition appliances—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants (April 6, quoting A. 81). An adviser in agricultural entomology in the University of Manchester—The Registrar, University, Manchester (April 19). A professor of anatomy in King's College, London—The Academic Registrar, University of London, South Kensington, S.W.7 (April 21). An instrument maker for experimental work in the Experimental Department of the Fine Cotton Spinners' and Doublers' Association, Ltd., Rock Bank, Bollington, Macclesfield—The Secretary. A demonstrator in the mechanical engineering branch of the Artillery College, Woolwich—The Assistant Commandant, Artillery College, Red Barracks, Woolwich, S.E.18. An agricultural entomologist at the Kirton Agricultural Institute—The Principal, Kirton Agricultural Institute, nr. Boston, Lincs. A junior chemist, and a senior laboratory assistant, under the Lancashire and Cheshire Coal Research Association—The Director of Research, Lancashire and Cheshire Coal Research Association, College of Technology, Manchester.

Our Astronomical Column.

Discovery of a New Comet, 1927 *d*.—A telegram from Prof. Shapley, circulated by the I.A.U. Bureau at Copenhagen, announces the detection of the fourth comet of 1927. The discovery was made by Dr. C. L. Stearns, at the Van Vleck Observatory, Wesleyan University, Middletown, Connecticut, on Mar. 10 at 10^h $4{\cdot}8^m$ U.T. in R.A. 15^h 16^m $6{\cdot}0^s$, south declination, 7° 21′ 43″. The comet was of the tenth magnitude, and its daily motion was -16^s, North 19′. On Mar. 19 it will be in R.A. 15^h 13^m 42^s, south decl. 4° 53′, assuming uniform motion. This is some 5° north of β-Libræ. Meridian passage will be about 3^h 30^m A.M.

Radio Reception and Solar Activity.—A paper entitled "The Correlation of Radio Reception with Solar Activity and Terrestrial Magnetism" is contributed by G. W. Pickard in the *Proceedings of the Institute of Radio Engineers*, Feb. 1927. The purposes of the paper are to emphasise the need for prolonged systematic observations of radio reception and to give preliminary results which have been obtained from data extending over nine months. At the outset it appears that poor broadcast reception coincided with practically every magnetic disturbance of note between 1922 and 1926 as registered at Cheltenham, U.S.A.; but in order to establish a more definite correlation, a series of nightly measurements of the radio reception at Boston of WBBM at Chicago (operating at 1330 kilocycles) was commenced early in 1926. Over this relatively short interval the author obtains a correlation factor of $-0{\cdot}89 \pm 0{\cdot}06$ between radio reception and magnetic character on a monthly average basis. The graph for monthly averages show little correlation with sunspots, but on using moving weekly averages it appears that an increase of solar activity is paralleled by an increase in magnetic disturbance and a decrease in reception. Another graph, giving weekly departures from monthly means of sunspots, magnetic character of days, and radio reception, shows a succession of peaks suggestive of the well-known 27-day interval relation between solar disturbances and magnetic storms. Other points of interest are, first, that the low frequency end of the radio spectrum is not very sensitive to solar disturbances, the most sensitive portion being apparently between 1000 and 1500 kilocycles; secondly, that although the magnetic storm and reception depression begin together, the storm reaches its maximum before reception is at a minimum and magnetic quiescence returns two or three days before reception is normal. It is greatly to be hoped that the observations will be continued to substantiate thoroughly these interesting preliminary results.

Solar Eclipse of June 29.—The Ordnance Survey has published a very useful map of the circumstances of the total solar eclipse across England and Wales on June 29 (Southampton : Ordnance Survey, 1927. 3*s*.). The scale is ten miles to the inch. The central line, north and south limits of totality, the lines where the magnitudes are 0·99, 0·98, 0·97, 0·96, the lines where the sun's altitudes are 10°, 11°, 12°, 13°, and those where central eclipse occurs at U. T. 5^h 20^m, 5^h 21^m, etc., to 5^h 28^m, are all laid down from computations made at the Nautical Almanac Office. As estimated corrections have been applied to the moon's positions calculated from Brown's Tables, the various curves should be accurate within a mile. The map shows contour lines for every 400 feet of altitude, the spaces between them being printed in different colours; this information is of use in selecting stations, as the sun is so low in Wales that it is important to ascertain whether high ground will interfere with the view.

The width of the track of totality is 28 miles on the west coast and 31 miles on the east coast; the speed of the shadow is about 100 miles per minute.

It may be mentioned that two excursions to the eclipse from London are announced; one by Messrs. Cook to Southport, the other by the L.N.E.R. to some point in Yorkshire near the central line. The departure from London is on the afternoon or evening of June 28, returning on the following afternoon. These should be very useful to observers pressed for time.

Research Items.

The Savignano Statuette.—M. Raymond Vaufrey in T. 36, Nos. 5-6 of *L'Anthropologie*, discusses the possible dating of the female statuette in serpentine discovered at Savignano. in the province of Modena, northern Italy, some three years ago, and now in the Museum of Ethnography and Prehistory of Rome. The question is of some importance in relation to the occurrence of different phases of the palæolithic period in the Po valley; but in default of stratigraphic evidence, it depends entirely upon morphological considerations. The statuette is 225 mm. high, and, if it be of palæolithic age, is the largest of these figures yet discovered. Its material is presumably of local origin, as similar serpentine occurs in the neighbouring Appenines of Emilia. The superficial details of the sculpture are much worn. In form the statuette is an elongated ellipse with the arms pressed close against the body; the legs join, the oblique position of the line of division suggesting the action of walking; the feet are not indicated The head is a prolongation of the body without indication of a neck, and is pointed. the general appearance being as of a head-dress falling over the shoulders. The breasts, abdomen, and thighs are prominent but beautifully sculptured. The genitalia are not indicated. The statuette is markedly steatopygous. Italian archæologists are not in agreement as to its probable age, one school represented by M. P. Graziozi attributing it to the Aurignacian. while M. U. Antonielli considers it neolithic. The statuette, however. strikingly resembles those of Barma Grande. The position of the arms clasped on the breasts is characteristic of the palæolithic type, for in statuettes of later date the hands support the breasts Notwithstanding the absence hitherto of evidence of the Aurignacian in the Po valley, its occurrence on other sites in Italy supports the attribution to this period.

The Emeryville Shell Mound, California —An exceptional opportunity for examining the structure and composition of one of the many shell mounds, nearly four hundred in number, on the shores of the Bay of San Francisco. occurred in 1924, when it was decided that the Emeryville Mound, one of the highest, should be levelled to make room for a factory site. The use of the steam shovel made it possible to examine the whole of a horizon at one time, while further excavations could be made at the base when the whole mound had been removed. A report of the investigations carried on in these favourable conditions by Mr. W. Robert Schenck has been issued as No. 3 of Volume 23 of the *University of California Publications in American Archæology and Ethnology*. As a whole, the results go to show a general uniformity of culture, though there was a number of periods of occupation The primary purpose of the settlement was to gather shellfish. The occupation would appear to have been seasonal; but all the groups who used the site were not identical; indications of difference exist. The culture was simple and not of a high level. Fires and basketry were known from the beginning. Food was probably cooked in the baskets by means of hot stones. Snares, traps, and wooden weapons were used rather than the bow and arrow. Sea food, obtained by raft, acorns, seeds, and other vegetable foods, were in use. Fish were caught by hook and line and not by net. Warfare was apparently infrequent, as few of the skeletal remains show signs of death from violence. Shell ornaments and beads were used on pipes and whistles. mortars and clothes. The grave furniture varied in different cases, even in infant burials, some interments being accompanied by many articles. others by none. Special groups of subjects—*e g* whistles, pipes, and charmstones—suggest a certain specialisation of occupation and social position. Objects of a ceremonial nature—crystals and charmstones—indicate the existence of a cult. while the scarcity of pipes points to the ceremonial nature of smoking. Burial was by inhumation or, more rarely, by cremation, graves occurring in groups near the dwelling-places. Artefacts buried with the dead were 'killed.' A speculative dating places the beginnings of the mound at about a thousand years ago.

Technical Terms in Brewing and Malting.—A list of technical terms used in the brewing, malting, and allied trades has been compiled by S. K. Thorpe, and appears in a recent number of the *Journal of the Institute of Brewing*, 33, 15; 1927). The list, which is very comprehensive and includes even commercial terms connected with the industries, contains a number of interesting notes on the origin and history of the words described. Words which deal with brewing are mostly of Flemish or Dutch origin, whilst those connected with barley or malting are of Celtic or Anglo-Saxon origin. Most of the words have preserved their original meanings throughout the ages, though the term "maltster" was probably a female "malter," just as a "spinster" was a female "spinner." "Ale" also was originally the name applied to sweet unhopped wort and was not identical with "beer," which was made from a weaker wort boiled with hops or a herb such as gentian. The word "bridal" or bride-ale" indicates its original connexion with feasting. In more recent times a new set of terms has evolved, though "cocktail," which dates from the American War of Independence, is usually thought to be of later origin. "Punch" is the subject of interesting speculation, since although derived from the Hindustani word "panch," meaning five (the number of ingredients), it is older than the British occupation of India, and may have come to western Europe via the Near East.

Scottish Salmon.—In a report on the salmon of the River Dee (Aberdeenshire) in 1923 (*Fisheries, Scotland, Salmon Fish.*, 1926, 4 (Sept. 1926)) Mr W. J. M. Menzies and Mr. P. R. C. Macfarlane confirm results obtained from examinations made in the two previous years. 1921 and 1922. A total of 1968 salmon and 833 grilse were examined. and information obtained on age. length, and condition is given, together with calculated lengths at the end of each year of life, as shown by scale readings. The 1 + and 2 winter groups have been the mainstay of the Dee salmon population during these years, the only other group of any importance being the 2 + group. February to April are exclusively spring fish months. May is characterised by a mixture of spring and summer salmon, and fish that seem to be in a transition stage between the two, these last being an obstacle to the theory that spring and summer salmon are of separate races. Previous evidence that fish which have already spawned return to fresh water for their second spawning in the same 'class' as on the first visit is confirmed. The majority of smolts at migration were two years old, although in 1922 the three-years-old smolts were rather plentiful. There is a distinct correlation between lengths attained each year: *e.g.*, large one-year parr become large two-year smolt, while small one-year parr become small second-year smolt, or remain in the river to become third-year smolt. This correlation is continued even in sea life.

ZOOLOGICAL EXPLORATION IN SIBERIA.—A special expedition of the Russian Academy of Science was working during the summer of 1926 in the Far East collecting insects and studying their distribution. More than 30,000 insects have been brought back by the expedition, and a preliminary study of the material, published in the *Information Bulletin* of the Academy, showed a large percentage of undescribed forms of all orders. A very striking feature of the collections is a very considerable number of species which have been previously known only from Japan and China. Of special interest is a giant longicorn beetle *Callipogon relictus* Sem., a representative of the fauna of relict Tertiary forests which is known only by a few specimens. A member of the expedition, Prof. A. K. Mordvilko, studied specially the Aphidæ (plant-lice), of which 215 species have been collected, many of them new, others known previously from Japan or China, while most of the European species are represented by special local races. Another small expedition of the Academy was studying at the same time the water fauna of Ussuri-land and of Lake Baikal. Special attention was paid to some less-known and little-collected groups of invertebrates, particularly to the Turbellaria. Of these, 40 fresh-water species have been found, 17 of them new to science, while nearly all of the 26 species collected in the Japanese Sea near the shores proved to be undescribed. A highly peculiar fauna of Turbellaria was found in Lake Baikal, where not less than 26 endemic species were discovered, some of them representing new genera and even new families.

THE MICROPLANKTON OF CHESAPEAKE BAY.—A very large amount of material has been collected for the quantitative study of the microplankton of Chesapeake Bay ("An Investigation of the Microplankton of Chesapeake Bay." By J. J. Wolfe and Bert Cunningham, with the assistance of N. F. Wilkinson and J. T. Barnes. *Journal of the Elisha Mitchell Scientific Society*, vol. 42, Nos. 1 and 2, Oct. 1926), which has been worked out by Mr. J. J. Wolfe and Mr. B. Cunningham. The samples were obtained by means of a water bottle and centrifuged, the volume of deposit measured, and portions of such deposit diluted and recentrifuged for counting. The investigations show that the Bay is by no means short of microscopic organisms, the average total for all collections distributed over two years being about 75,000 per litre, the largest collection being more than three million per litre. When one considers that a very large number of minute cells were probably not seen, judging from the lists given, this shows it is not at all poor. The authors are of the opinion that the most important factor in the growth and increase of the diatoms is temperature, the range in the Bay being from 30° F. to 76° F., the optimum temperature for diatoms being between 46° F. and 55° F. On the other hand, the protozoa, including dinoflagellates, are at their lowest at these temperatures and highest when the diatoms are low. Taking the total number of organisms throughout the year, there are two maxima, one in spring and one in autumn. These are usually due to diatoms, but high up in the Bay in autumn in two areas the cause is the dinoflagellate Prorocentrum, and these are the regions of low salinity. The spring maxima are almost always caused by diatoms, the largest numbers being due to Chætoceros, Skeletonema and Rhizosolenia also being very common. The voluminous mass of data relating to the above studies is filed with the Bureau of Fisheries, where it will be valuable for future reference when more investigations with regard to available fish food are undertaken.

CILIATED PROTOZOA AND CONTRACTILITY.—In a communication made to the Royal Lombardy Institute of Science and Letters, Prof. Antonio Pensa describes his observations on ciliates of the genus Balantidium, found as parasites in the intestine of the frog. These organisms prove capable of motion independently of the cilia, more especially when progress with the help of the cilia is retarded by the conditions of the surrounding medium. Such secondary movement results from contractility of the plasma and may be superposed on the principal effect due to vibration of the cilia so as to exert a modifying influence. The contractility is manifested mainly by the appearance of furrows, which may be either partly or completely annular. These furrows originate at the anterior part of the animal and undergo gradual backward displacement, the more fluid portion of the endoplasm apparently flowing at the same time in the opposite direction. The contractile wave stops when it reaches the posterior extremity of the animal, which then moves with a slight leap. If the furrow is circular, complete, and perpendicular to the axis of the body, the displacement is directly forward, but with a complete and inclined furrow it is perpendicular to the plane of the furrow and hence oblique and lateral; lateral motion towards the side occupied by the furrow occurs when this is partial and lateral. Another characteristic form of contraction consists in a rapid and circumscribed retraction of the posterior pole of the protozoon; this phenomenon is often almost rhythmic and effects arrest of the progress caused by ciliary vibration. Localised retraction of the posterior pole may determine a slight backward impulse. There seems little doubt that these contractions are proper to the endoplasm and are due to a peculiarity of structure or constitution which may be rendered evident by the application of silver reduction methods.

COAST AND GEODETIC SURVEY IN THE UNITED STATES.—The report of the United States Coast and Geodetic Survey for the year ending June 30, 1926, has been issued. In addition to revision of coast surveys in the United States, progress was made in those of oversea possessions. Coast surveys of the Philippines are almost complete except for the north-east coast of Luzon and parts of Palawan and of the Sulu archipelago. In the Hawaiian Islands there are still some gaps in the hydrographic survey and a few in the coast topographic survey. Work on the approaches to the Panama Canal and on the waters and coasts of the Virgin Islands and Porto Rico is practically finished. Good progress was also made in Alaska. Work was continued in the readjustment of the first-order triangulation to the westward of the ninety-eighth meridian in the United States, and there is the usual record of magnetic and tidal work. A matter of some interest in the report is a statement regarding the redetermination, this time by radio time signals, of the old longitude station at Seattle, Wash. A comparison between the old and the new determination showed a difference of only 0·003 second. The report contains a large number of index maps showing the present state of coastal surveys in American territory.

FOSSIL PERMIAN INSECTS FROM EUROPEAN RUSSIA. —While there is a considerable number of records of fossil Permian insects from North America, practically nothing was known of them in Europe. It is therefore interesting to learn from the *Information*

Bulletin of the Russian Academy of Sciences that Dr A. V. Martynov was fortunate enough to discover and collect a good series of these fossils on the shores of the river Kama, in northern European Russia. Best represented in the collection are Homoptera and Mecoptera; then there are some highly interesting Protorthoptera, also Neuroptera, Psocoptera, and others. A preliminary study of the collection permits one to conclude that the fauna was somewhat similar to the Permian fauna of Kansas, but not identical with it, since not only genera, but even families, were different though related to those of Kansas. More extensive and detailed investigations are proposed during the next season.

X-Ray Spectroscopy.—The issues of the *Physikalische Zeitschrift* for Jan. 1 and 15 contain a report of 70 pages by Dr. A. E. Lindh on the development of Röntgen or X-ray spectroscopy during the years 1921-1925. It comprises the following subjects: Apparatus—tubes and spectrographs—the development of technique, the gratings, the deviation from the simple law $n\lambda = 2d \, . \sin \theta$, refraction and total reflection, emission spectra, the K, L, M, and N series, absorption of the K, L, and M series, the conditions for the production of the various lines, the measurement of their intensities, their energy levels, the influence of chemical structure on spectra, the Compton effect, and the β-ray spectra. The report, which devotes 10 pages to the literature of the subject, will prove of great value to those working in this field.

Measuring Zonal Aberrations.—Part 1 of Volume 28 of the *Transactions of the Optical Society* contains an account of the method of determining the foci of the various zones of an optical system invented by Mr. Conrad Beck and communicated to the Society on Nov. 11 last. An accurately centred metal disc has two short slits cut in it with their centres at opposite extremities of a diameter of the zone to be investigated, and with their directions making with the diameter an isosceles triangle with basal angles 45°. The width of each slit is about one-third the length. Light from a fine hole in a silvered glass surface placed in the axis of the system is allowed to pass through the slits to the system, by which it is brought to a focus. The exact position of the focus is determined by the fact that at the focus the diffracted images of the slits form a symmetrical cross. By the use of discs with the slits at different distances apart, the focus for each zone and the zonal aberration may be determined.

Concentration of Water Vapour in Compressed Gases.—An important paper on the concentration of water vapour in compressed hydrogen, nitrogen, and mixtures of these gases in the presence of condensed water has been published by E. P. Bartlett in the *Journal of the American Chemical Society* for January 1927. The water vapour content depends on the nature of the saturated compressed gases, and the values calculated from the ordinary gas laws differ considerably from those actually observed. Thus, volume for volume, at 1000 atmospheres and 50°, nitrogen will hold 44 per cent. more water vapour than will hydrogen, and the water-vapour contents are much larger than the theoretical. No thermodynamical relations have been found that will connect the observed and calculated results. The phenomena are explained qualitatively by assuming that the compressed gas is a solvent for water vapour.

Frequencies Employed in Speech and Music.—In the *Bell Laboratories Record* for February, an account is given of phonograph records that have been made to demonstrate the effects of excluding notes of definite pitch from speech and music. The research was made by the American Telegraph and Telephone Company with the object of improving telephony. Electrical 'filters' were employed which could suppress sounds of a given range of frequencies. The frequency of the vibrations occurring in speech vary from about 100 to 8000 cycles per second. The effect of cutting out all the vibrations below 375 per second is to alter the character of the voice, although the intelligibility remains perfect. When all sounds having a frequency less than 750 were eliminated, the voice sounded most unnatural and had no character. The vowel sounds were badly distorted, but the speech could be interpreted mainly through the consonant sounds. When all the lower vibrations are restored but those having frequencies greater than 2500 are suppressed, the voice sounds natural but the interpretation is not good. When all the vibrations above 1000 are suppressed, the speaker's voice has a guttural character, and it is very difficult to understand what he says. Whole phrases are sometimes missed, owing apparently to the absence of consonant sounds. Another record shows similar effects produced in transmitted music when sounds of certain frequencies are suppressed. When the filter passes only the frequencies above 375 the melody is present but the tonal character is missing. When all sounds below 750 are suppressed, the music assumes a tinkling character. When the higher notes above 2500 are eliminated the music becomes dull, all the brilliance of tone disappearing. If all the notes above 1250 are eliminated the music becomes practically a thumping noise. Another record shows the effects of forcing a vacuum tube to carry more than its rated load. In this case harsh extraneous sounds called 'buzzing' and 'rattling' are introduced.

Philosophy and Physics.—The greatest workers in mathematics and physics have always been philosophers as well. A complete insight into these subjects is impossible without philosophy. In "Het Nut van het Wijsgeerig Denken in Wis-en Natuurkunde," Dr J. H. Tummers deals in an interesting manner with the benefit to be derived by mathematicians and physicists from philosophical thinking. While the whole of the contents of the brochure may not receive universal acceptance, it can be read with profit by all. In developing his thesis, Dr. Tummers sketches the history of the ether from the beginnings of the wave theory of light up to the Michelson-Morley experiment. The failure of the latter to show us the ether recalls to mind Planck's axiom, "Only that which can be measured exists." Einstein, contemplating the experiment in this light, has shown us how to do without the ether. This aspect of the theory of relativity and the changes which the latter has brought about in our ideas of space and time are next considered. It is emphasised that we must look inside the mathematical superstructure and find out what are the philosophical bases of the theory—what is contained in and implied by the differential equations. Before dealing with the ideas of space and time of the theory of relativity, Dr. Tummers sketches the philosophical and mathematical bases of the various geometries which have been proposed. He discusses the idea of the geodesic and shows how the geometries of Riemann and Lobattschewski are equivalent to ordinary Euclidean geometry on the surface of a sphere and on a Beltrami surface respectively. These geometries stand on an equal footing as regards their being 'true.' Einstein has not shown that space is non-Euclidean, but that the phenomena of Nature can be more conveniently represented by a non-Euclidean concept of space.

Forthcoming Books of Science.

Agriculture, Forestry, and Horticulture.

George Allen and Unwin, Ltd.—The Physiological Basis of Drought-Resistance in Plants, N. A. Maximow. Translated from the Russian, edited by Prof. R. H. Yapp; The Evolution of the English Farm, M. E. Seebohm. *Cambridge University Press.*—The Physiology of Reproduction in the Cow, J. Hammond; The Economics of Small Holdings, E. Thomas. *Chapman and Hall, Ltd.*—Teaching Agricultural Vocations, Stewart and Getman. *John Murray.*—A Primer of Agricultural Economics, Sir Henry Rew. *Oliver and Boyd.*—The Potato, P. M'Intosh. *Kegan Paul and Co., Ltd.*—Year Book of Agricultural Co-operation in the British Empire, with a Census of Producers' Organisations, edited by the Horace Plunkett Foundation. *Charles Scribner's Sons.*—The Beginner's Garden, Mrs. F. King.

Anthropology and Archæology.

D. Appleton and Co.—The American Indian: North, South, and Central America, A. H. Verrill. *Cambridge University Press.*—The Naron, D. F. Bleek (first of a series of Publications of the School of African Life and Languages); Papers on the Ethnology and Archæology of the Malay Peninsula, I. H. N. Evans. *W. Heffer and Sons, Ltd.* (*Cambridge*).—A Study of Races in the Ancient Near East, W. H. Worrell. *Macmillan and Co., Ltd.*—The Kiwai Papuans of British New Guinea, Dr. G. Landtman; The Circle and the Cross, A. Hadrian Allcroft, 2 vols., Vol. I., The Circle; Vol. II., The Cross. *Methuen and Co., Ltd.*—The Civilisation of Greece in the Bronze Age: The Rhind Lectures on Archæology (1923), Dr. H. R. Hall. *Kegan Paul and Co., Ltd.*—Melanesians of the South-East Solomon Islands, Dr. W. G. Ivens; The Civilisation of the South American Indians, with special reference to Magic and Religion, Prof. R. Karsten.

Biology.

George Allen and Unwin, Ltd.—Birds and Beasts of the Roman Zoo, Dr. T. Knottnerus-Meyer, translated by Bernard Miall. *G. Bell and Sons, Ltd.*—Readable School Biology, O. H. Latter (Bell's Natural Science Series). *A. and C. Black, Ltd.*—Natural History: Animals, G. Jennison. *Cambridge University Press.*—Bibliography of Sponges, 1551–1913, by the late Prof. G. C. J. Vosmaer, edited by Dr. G. P. Bidder and C. S. Vosmaer-Roell; A Treatise on the British Freshwater Algæ, by the late G. S. West, new and revised edition by Prof. F. E. Fritsch, The Structure and Development of the Fungi, Dame Helen Gwynne-Vaughan and B. Barnes. *Chapman and Hall, Ltd.*—Evolution, B. Gruenberg; Text-book of Zoology, Curtis and Guthrie; Biochemical Research Methods for Students of the Biological Sciences, Morrow. *Epworth Press.*—British Wild Fruits and How to Identify Them, R. Morse ('How to Identify' Series). *Longmans and Co., Ltd.*—Plant Autographs and their Revelations, Sir Jagadis Chunder Bose; Magnolias, J. G. Millais. *Methuen and Co., Ltd.*—Science Studies, Sir Ray Lankester. *F. Warne and Co., Ltd.*—Bird Life at Home and Abroad, T. A. Coward; Favourite Flowers of the Garden and Greenhouse, E. Step, in 13 fortnightly parts.

Chemistry.

G. Bell and Sons, Ltd.—Practical Physical Chemistry for Schools, Dr. J. F. Spencer (Bell's Natural Science Series). *Ernest Benn, Ltd.*—The Making of a Chemical, E. I. Lewis and A. A. King; The Manufacture of Ammonium Products, P. Parrish; The Chemical Age Dictionaries, II. The Dictionary of Organic Substances; Encyclopædia of the Ceramic Industries, A. B. Searle; Chemistry, Dr. P. E. Spielmann. *Chapman and Hall, Ltd.*—Introduction to Physiological Chemistry, Bodansky; Nature Origin and Interpretation of the Etch Figures of Crystals, Honess; Experiments in Organic Chemistry, Underwood; Colloids, Kruyt and Van Klooster; Organic Syntheses, Whitmore, Vol. VII. *C. Griffin and Co., Ltd.*—Foods: their Composition and Analysis, Dr. A. Wynter Blyth and M. Wynter Blyth, revised by Dr. H. E. Cox, new edition. *Longmans and Co., Ltd.*—Flame and Combustion in Gases, Prof. W. A. Bone and Dr. D. T. A. Townend. *Sir Isaac Pitman and Sons, Ltd.*—A Course of Volumetric Work, E. Clark.

Engineering.

Ernest Benn, Ltd.—Electric Switch and Controlling Gear, Dr. C. C. Garrard, new edition; Insulated Electric Cables, Vol. II: Manufacture and Installation, C. J. Beaver; Electric Winders, H. H. Broughton; Colloid Mills, Dr. S. P. Schotz; Sinking Shafts and Driving Adits, E. O. F. Brown. *Chapman and Hall, Ltd.*—The A. C. Commutator Motor, C. W. Olliver; Tables of Safe Loads on Steel Pillars, with Practical Notes on Design and Construction, E. S. Andrews and W. C. Cocking, Vol. I.; A Short Text-book on Sewage Disposal, T. H. P. Veal; Electric Rectifiers and Valves. Prof. A. Gunther-Schulze, translated by N. A. de Bruyne; Electrical Engineering Practice, J. W. Meares and R. E. Neale, Vol. II.; Hydro-Electric Handbook, Creager and Justin. *Constable and Co., Ltd.*—Propagation of Electric Currents in Telephone and Telegraph Conductors, Dr. J. A. Fleming, new edition; The Practical Design of Irrigation Works, W. G. Bligh, new edition; The Diesel Engine for Land and Marine Work, A. P. Chalkley, new edition; Designs of Small Oil-engined Vessels, W. Pollock. *C. Griffin and Co., Ltd.*—Overhead Electric Power Transmission Practice, W. T. Taylor; Pocket-Book of Electrical Rules and Tables, Munro and Jamieson, under the general editorship of W. R. Cooper and Rollo Appleyard, new edition, Carbonisation Technology, and Engineering, the Production of Coke, Charcoal, and other Fuels, J. Armstrong; Lubrication and Lubricants, L. Archbutt and R. M. Deeley, new edition. *Crosby Lockwood and Son.*—Water-Power Practice: The Principles, Practice, and Development of Water Power, F. Johnstone-Taylor; Sewage Works, F. C. Wind Drift.

A STRONG wind at sea has long been known to cause a drift of the upper layers of water superimposed upon the regular and periodic tidal currents. Sailing coastwise in clear weather, the navigator can determine the position of his vessel by bearings on landmarks, but in thick weather he can no longer do this, and it then becomes a matter of importance to know the velocity and direction of the currents, both tidal and wind-blown, to which his vessel may be subject. In sailing and slow-moving ships, seamen have need to make a rough allowance for this wind drift, in addition to the leeway made by the vessel, when calculating their position by dead reckoning in bad weather. The necessary allowance has never been more than a guess, usually on the assumption that the wind-blown current runs in the direction of the wind, simply augmenting or decreasing the normal speed of the tidal currents.

The early theory due to Zoppritz was based on a consideration of the internal friction of sea-water in regular motion, and took no account of either eddy motion in the water or the effect of the rotation of the earth upon the wind-driven current; it fitted in with the general experience of seamen, but did not accord with later observations of the drift of the ***Fram*** in the polar ice, during 1893–95, when the ice drifted some 28° to the right of the wind's direction and proceeded on the average at 2 per cent. of the wind's velocity. A mathematical consideration of the forces due to the tangential pressure of the wind on the surface and the rotation of the earth acting upon particles of water in motion led Ekman to conclude that, unless constrained by land or shallow depths, the surface water would move 45° to the right of the wind's direction throughout the northern hemisphere and at greater angles with decreasing velocity at greater depths. Observations of the upper 10 cm. to 60 cm. of water at a number of Finnish and Swedish light vessels in the Baltic showed a movement some 19° to the right of the direction of the wind. The speed was nearly twice as great when the wind blew in the same direction as the coast line, than when blowing directly on shore or off shore. The average speed of the current varied, not directly with the wind's velocity as occurred with the polar ice, but with its square root.

A number of other estimates of the relation between the velocity of this surface drift and of the wind have been made, but they show no general agreement; a few observations suggest that this deviation from the direction of the wind increases with depth, as would be expected from Ekman's conclusions, but the depth to which these currents extend in varying circumstances is unknown. This facet of the subject is one of some practical interest in fishery research; for example, the young of herring born in the English Channel are carried by such a current into the North Sea.

The need for accurate knowledge of the wind drift as well as the tidal currents along the Pacific coast of the United States, where harbours are many miles apart, sailing courses long and periods of thick weather not infrequent. has led the U.S. Coast and Geodetic Survey[1] to collect and analyse numerous current data from five light vessels. After allowing for the calculated tidal current the residual drift, almost entirely due to wind, was obtained for several thousand observations. These were made by means of a pole 15 ft. long, weighted at one end and floating 1 ft. out of the water'; no allowance is made for the pressure of wind on the exposed part of the pole.

The velocity of the wind drift set up by winds varying between 10 miles and 60 miles an hour was approximately 2 per cent. of the velocity of the wind, being slightly under this value for high winds. This is a similar relation to that found by Nansen for the polar ice, but an entirely different relation from that found by Whitting for the surface 10 cm. to 60 cm. in the Baltic. The latter also holds for the surface 15 cm. in the English Channel and North Sea, as deduced from the drift of bottles so weighted that only about 3 c.c. of the cork end floats above water.

The direction of the wind drift along the Pacific coast averaged 23° to the right of the wind's direction, except for winds from the south-west sector, in which case the coast line trending north and south constrained the current to move north, 24° to the left of the wind's direction.

The observations recorded by the U.S. Coast and Geodetic Survey are a definite addition to the data available, and have in consequence a wider interest than that of the purpose for which they were primarily made.

---

[1] U S Coast and Geodetic Survey Special Publication, No. 121, pp. 80. Coastal Currents along the Pacific Coast of the United States. By H A. Marmer. (Washington, 1926)

The Japanese Earthquake of Mar. 7, 1927.

FOR the second time since the great earthquake of Sept. 1, 1923, Japan has been visited by a destructive earthquake. The Tajima earthquake of May 23, 1925, was followed on Mar. 7 at 6.28 P.M. (or 9 28 A.M. G.M.T.) by another in nearly the same district, but probably some miles to the east. According to the official report issued from Tokyo, the central zone covers the counties of Naka and Yosa in the province of Tango. It is also stated that the roads to the north of Maizuru are impassable owing to the deep fissures caused by the earthquake. Thus, the centre must be close to the west coast of Wakasa Bay on the Japan Sea side of the islands.

In the small towns of Mineyama, Iwataki, Kaetu, Amino, Kayamachi, Ishida, and Yamada, containing from two to four or five thousand inhabitants, most of the houses are demolished or destroyed by the fires that broke out afterwards. As these, however, are not industrial centres, the purely economic effects of the earthquake will not be serious. The great towns of Osaka, Kyoto, and Kobe, to the south of the earthquake-zone, though strongly shaken, have suffered but little damage. The total number of lives lost is reported to be 2459.

The name of the province of Tango appears but seldom in Sekiya's catalogue of Japanese earthquakes. About fifty miles to the south, however, lies the important seismic district of Kyoto, and about the same distance to the east and south-east are the provinces of Mino and Owari, in which occurred one of Japan's greatest earthquakes, that of Oct. 28, 1891, with its remarkable fault-displacements.

Though their results in the loss of life and the destruction of property have been serious, both the earthquake of 1925 and that of Mar. 7 last are typical examples of the earthquakes that occur on the Japan Sea side of the islands. The late Prof. Omori divided the destructive earthquakes of Japan into two classes, local and non-local, according as they affected one province or several provinces. From the fifth century to near the close of the nineteenth century there were 221 destructive earthquakes in Japan. On the Japan Sea side of the islands there have been scarcely any but local shocks, while the Pacific side has often been shaken by great non-local earthquakes.

C. DAVISON.

University and Educational Intelligence.

CAMBRIDGE.—S. Goldstein, St. John's College, and W. V. D. Hodge, St. John's College, have been awarded Smith's Prizes for essays on "Mathieu Functions" and "Linear Systems of Plane Algebraic Curves of any *Genus*," respectively. D. Burnett, Clare College, and C. A. Meredith, Trinity College, have been awarded Rayleigh Prizes for essays on "Electric Radiation over the Earth's Surface," and "Some Theorems on Infinite Cardinals," respectively.

The General Board of the Faculties has recommended that the Disney professorship of archæology shall be brought under the new statutes for election, tenure, and duties; that its stipend be raised from the endowment to £1200 a year; that it shall be assigned to the Faculty of Archæology and Anthropology, and that the field within which the professor shall give instruction shall be classical, medieval, and prehistoric antiquities and fine arts.

It is proposed to appoint Mr. H. Quinney as an assistant in experimental research in the engineering department.

APPLICATIONS for grants in aid of scientific investigations bearing on agriculture, to be carried out in England and Wales during the academic year beginning on Oct. 1 next, must be made to the Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1, by May 15 next. The Ministry is offering not more than seven research scholarships in agricultural and veterinary science, each tenable for three years, applications for which must be made not later than June 30 next; it also invites applications for not more than five agricultural scholarships tenable for two years. The latest date for the receipt of applications is June 30.

A PAPER on "University Government with special reference to the University of London" was read by Mr. T. Ll. Humberstone at the Education Guild on Mar. 9, Sir Richard Gregory presiding. After describing the origins and constitutions of the archetypal universities, Bologna and Paris, the university of students and the university of masters respectively, he pointed out that Oxford and Cambridge were modelled on Paris, and remained true to type as autonomous societies of masters. These universities have handed down from the Middle Ages a tradition of a self-governing community with full freedom of opinion as precious as their dreamy spires and moonlit lawns. Referring to the proposed new constitution of the University of London, he emphasised the importance of ensuring a high standard of attendance in the Council. Convocation representation on the Senate should bring the University into touch with the world of affairs, the professions, and industries. Mr. Humberstone is opposed to any extension of institutional representation on the Senate, considering that college principals should be selected and appointed on grounds of personal merit. The Principal of the University should be a member of the Council and of the Senate *ex officio*, as there is no warrant in the constitutional history of universities for the exclusion of a high officer from membership of the governing body. He urged that special attention should be given to methods of voting. There is need for greater publicity as to the work and aspirations of the University. The chairman agreed that the question of the status of the Principal should receive attention, and strongly supported the plea for greater publicity; support of the University would be more generous if the needs of the University were explained.

Calendar of Discovery and Invention.

March 20, 1800.—It was in his letter addressed "a Como en Milanois, ce 20 m Mars 1800," that Volta communicated to Sir Joseph Banks his discovery of the voltaic pile. The letter arrived in parts, but the whole was read to the Royal Society on June 26, 1800. From the information contained in the first part, Nicholson and Carlisle made a pile with 36 half-crowns and 36 zinc discs, and with this they decomposed water.

March 20, 1877.—Fifty years ago, on Mar. 20, 1877, in his presidential address to the Iron and Steel Institute, Sir William Siemens directed attention to the possibility of utilising the power of Niagara Falls for driving dynamos and for transmitting electricity over long distances for lighting and smelting. Thirteen years later the Niagara Commission, including Kelvin, Mascart, Sellers, Turretini, and Unwin, was appointed; in 1893 a contract was placed with Westinghouse, and in 1895 three 5000-h.p. machines were started. To-day more than half a million horse-power is developed by the various plants.

March 21, 1816.—The Royal Academy of Sciences of Paris was founded by Colbert in 1666. During the Revolution, in 1793, all the academies were suppressed, but two years later the National Institute was founded. With the Restoration, further changes were made, and on Mar. 21, 1816, the academies were placed on their original footing. It was at this time also the names of Carnot and Monge were removed because in 1792 they had voted for the death of the king.

March 22, 1792.—A notable improvement in rapid communication resulted from the invention of the semaphore by Claude Chappe, which he laid before the Legislative Assembly of France on Mar. 22, 1792. During trials a message was sent from the Louvre to Lisle, 48 leagues distant, in thirteen minutes. The semaphore was extensively used during the Napoleonic Wars, and up to 1849 the Admiralty maintained a chain of semaphore stations at Chelsea, Putney, Kingston, Esher, Cobham, Guildford, Godalming, Haslemere, Midhurst, Petersfield, and Portsdown. Chappe's monument stands in the Boulevard Saint Germain.

March 24, 1787.—On Mar. 24, 1787, Dalton made his first entry in a book entitled "Observations of the Weather, etc." During the course of the next fifty-seven years he entered some 200,000 observations in this journal, the last being made the evening before his death.

March 25, 1655.—To-day Saturn is known to have ten satellites. The first discovered and the largest, Titan, was seen by Huygens on Mar. 25, 1655. Between 1671 and 1684, Cassini discovered four more; Herschel added two in 1789, Bond and Lassell found Hyperion in 1848, while Pickering discovered the other two in 1898 and 1904 respectively. Phœbe, which was found in 1898, has a motion in the opposite direction to the other nine.

March 26, 1762.—In 1713 an Act of Parliament authorised the award of sums of £10,000, £15,000, and £20,000 for determining the longitude at sea within 60, 40, and 30 miles respectively. Many astronomers and mechanicians assisted in the solution of the problem, but the principal work was done by John Harrison, the inventor of the marine chronometer. His seagoing timepieces were made in 1735, 1739, 1749, and 1759, and it was with the fourth that his son made a voyage from Portsmouth to Jamaica and back, the voyage lasting from Nov. 18, 1761, to Mar. 26, 1762. During this time the error only amounted to 1 min. 54¼ sec.

E. C. S.

Societies and Academies.

London.

Royal Society, Mar. 10.—**A. Levin** and **J. Wyman**: The viscous elastic properties of muscle. 'Viscosity' is a term used to denote irreversible processes which cause a loss of work, greater with greater speeds, and prevent the muscle from contracting instantaneously. A mechanical model consisting of two elastic elements (springs), of which one only is damped, will imitate muscular effects, and it is argued that the muscle is mechanically a system of this type. When the muscle is stimulated isometrically, tension is shared by the damped elastic and free elastic elements. When the muscle is then released at a constant rate, the damped elements lag behind, causing thereby a drop of tension, which, however, is not instantaneous, owing to the presence of the free elastic elements. As the shortening proceeds, a steady state of lag is reached exponentially. When the release stops, the damped elements continue to shorten, stretching the free elements, and the tension redevelops exponentially. In a stretch the events occur in the opposite order. The actual contractile structures are the damped elements. The free elastic elements act as 'buffers.'

F. W. R. Brambell and **A. S. Parkes**: Changes in the ovary of the mouse following exposure to X-rays. 75 per cent. of the animals killed upwards of five weeks after irradiation, when adult, were sterilised. No hiatus occurred in the œstrous cycles following irradiation. The elements already forming the cortex at the time of irradiation persist and constitute the tissues of the sterilised ovary. They are derived from the embryonic germinal epithelium and produce œstrin in the normal ovary; they continue to do so without interruption after irradiation. 'Anovular' follicles were formed from the smaller follicles, by the degeneration of the oocytes and the growth of the membrana granulosa cells, immediately after irradiation.

A. S. Parkes, **Una Fielding**, and **F. W. R. Brambell**: Ovarian regeneration in the mouse after complete double ovariotomy. Of 121 double ovariotomised mice, all of which showed initial cessation of the œstrous cycle, eleven afterwards showed signs of spontaneous œstrus. In eight of these eleven cases the presence of new ovarian tissue was demonstrated histologically. The exact site of regeneration could not be ascertained. In most cases follicles and corpora lutea were found in the regenerate tissue, and generally these cyclic structures could be correlated with the recent œstrous history of the animal. Most of the regenerate animals had a normal cycle after the first spontaneous appearance of œstrous symptoms, but in at least one case a very irregular series of œstrous-like phenomena occurred, prolonged cornification being the chief feature observed.

A. Walton: The relation between 'density' of sperm-suspension and fertility as determined by artificial insemination of rabbits. Experiments on artificial insemination of rabbits show that fertility is influenced by the density or number of spermatozoa introduced into the vagina of the female. Fertility is reduced where the estimated number of spermatozoa is less than about 10^6 per 3 c.c. Sterility occurs where the number is below 10^4 per 3 c.c. Three factors probably play a part in determining the results, but are not subject to separate quantitative estimation:—(*a*) The probability of any one spermatozoon reaching the fertilisable ovum is small; (*b*) the spermatozoa are not all capable of fertilisation; (*c*) toxicity may act differentially on sperm-suspensions of varying density.

Alexander Hynd: The action of glucosone on normal animals (mice) and its possible significance in metabolism. The subcutaneous injection of glucosone, a first oxidation product of glucose, in appropriate dosage, produces in normal mice a condition very similar to that caused by insulin, the symptoms being modified or inhibited by an injection of either adrenaline or pituitrin. The 'glucosone effect,' however, is not remedied by the administration of glucose. An injection of acetoacetic acid antagonises the effect of a glucosone injection, indicating that glucosone may be of significance in fat metabolism. Glucosone is, perhaps, formed by the action of insulin on blood sugar, and thus may be an important compound in the intermediate metabolism of carbohydrates.

Cambridge.

Philosophical Society, Jan. 31.—**Sir Joseph Larmor**: What determines the resistance and tilt of an aeroplane? Formulæ were given by J. J. Thomson in 1883, in which the six components of the resultant momentum in an unlimited field of fluid motion were expressed in terms of the distribution of vortical spin alone. When they are extended, in intrinsic invariant form, so as to apply to regions of a field of motion produced by solid bodies, passive or propelled, they ought to provide a formal foundation, possibly of technical value, on which to base the general dynamics of propulsion of an aeroplane or airship. Applications are made, for example, to the necessity for opposite nearly compensating vorticities in the wake: also, the relation to the current procedure which derives the supporting force from a definite smooth circulation of the air around the body: also, and historically, the nature of the process by which mainly a system of vortices is thrown off from a travelling solid body, which only later degrades into tumultuous disturbance.—**L. H. Thomas**: The effect of the orbital velocity of the electrons in heavy atoms on their stopping of α-particles. 'Collisions' between α-particles and electrons are divided into two classes; close collisions, which may be treated as if the electron were free, and slight collisions, which may be treated as small disturbances of the electron. For swift α-particles the two classes overlap. The second type of collisions is neglected altogether and the first type arbitrarily delimited as those for which the transfer of energy is larger than the ionisation potential (Henderson's assumption). For swift particles and heavy atoms the error so introduced is comparatively small. On the average a particle loses more energy to a moving electron than to a stationary one.—**F. H. Constable**: Surface adsorption and the velocity of chemical action at gas-solid interfaces. The formula previously deduced connecting the partial pressure of the reactant in a mixture with the fractional reaction velocity has been verified for mixtures of alcohol vapour diluted with water, acetone, and benzene; and for the composition of the adsorbed film on platinum exposed to mixtures of carbon monoxide and oxygen. The effect of the mixture of vapours on the temperature coefficient of reaction is considered. If the heat of desorption of the reactant is greater than that of the diluent, then the temperature coefficient is diminished; if they are equal, there is no alteration; and if less, the temperature coefficient is increased. Water present as a diluent in alcohol has little effect on the temperature coefficient of the reaction.—**H. D. Ursell**: The evaluation of Gibbs' phase integral for imperfect gases. The phase integral for a perfect gas (neglecting the factor corresponding to impulse co-ordinates) is V^N. It has sometimes been assumed that in general the value is $V^N(1+g)$ where g is of the order of the imperfection. This, however, is not correct, the form taken being actually $V^{N}e^{N\prime}$, and this fact invalidates any simple discussion of an imperfect gas. An exact expression is obtained for the phase integral in the form of a multiple series, from which different equations are written down which equally define it. When these have been expressed in terms of g it is possible to approximate, and thus to evaluate g, and hence the pressure, to any order for a given molecular model.

MANCHESTER.

Literary and Philosophical Society, Feb. 8.—**Wilfred Irwin**: The presence and distribution of salt in the air, rain, and rivers of this country. Samples were taken at twelve different stations in England simultaneously, each sample representing three months' rainfall at those stations. This was done during a stormy winter quarter, and again during a calm spring quarter. In the stormy period the content of the salt may vary from 199 parts per million at Maryport on the sea coast in Cumberland, to 5¼ parts at Ryton on Dunsmore in Warwickshire, and in the mild period from 32 parts at Maryport to 5 parts at Ryton. In urban areas, chlorides are emitted along with smoke and the results are very irregular. Lakes in the Lake District were tested for salt; with the exception of Derwentwater and Bassenthwaite, which are influenced by the saline spring at Brandlehow, results show that Loweswater, the gathering ground of which is nearest to the sea, contains the most salt—16 parts per million—and that Haweswater, the farthest from the sea, has the least—only 8 parts. The salinity of the rainwater over England and Wales probably averages about 7 to 8 parts per million, and the average rainfall, 35 inches. This means that about one million tons of solid salt are annually carried in spray from the sea to the land, to be returned by the rivers to the sea. It is calculated that to bring the land in Warwickshire to the same salinity as that in the neighbourhood of Cockermouth, one hundredweight of salt per acre would be required to be added.

Feb. 22.—**D. C. Henry**: Some recent advances in colloid theory. Experiments recently made at the Cambridge Low Temperature Research Station on the freezing of gelatin gels throw some light on the constitution of such gels. In one series, measurements were made of the velocity with which the crystallisation of water is propagated through a supercooled gel when 'seeded' with a small particle of ice. Whereas a 1 per cent. gel does not greatly hinder the crystallisation process, a 2 per cent. gel reduces the crystallisation velocity to less than a tenth of its value in water, except in the immediate neighbourhood of the isoelectric point. In this neighbourhood the gel is turbid instead of clear, and it is probable that opaque fibrils are formed at the expense of the main structure of the gel, which is thus weakened sufficiently for the ice to break through without much hindrance. A second series of experiments has established the existence of a reproducible equilibrium between ice and gel of a definite concentration, varying with the temperature, and leads to definite conclusions as to the proportion of the water in a gelatin gel which may be considered as 'bound' to the gelatin.

PARIS.

Academy of Sciences, Feb. 7.—**P. Villard**: The chemical actions of radiations. Remarks on a recent note of A. Gargam de Moncetz.—**E. Mathias**: Contribution to the study of fulminating material. The decomposition of a certain kind of globular lightning, spontaneous and without sensible noise.—**Charles Jordan**: A generalised case of the probability of repeated trials.—**Paul Alexandroff**: A definition of Betti's numbers for any closed ensemble.—**E. Lainé**: The method of Darboux and Moutard's equations.—**P. Lejay**: The synchronisation at a distance of precision pendulums without use of any contact. A method is described which would appear to be applicable in other directions also. A small heterodyne short wave emitter is placed in the same room as the pendulum. To the condenser of the oscillating circuit which fixes the wave-length, a 20 cm. wire is connected and arranged so that the pendulum in oscillating passes some millimetres from its free extremity. The resulting variation of capacity of the wire with respect to the pendulum causes a sufficient variation of the wave-length to produce a record in the ordinary way. The notches produced on the record are perfectly symmetrical and have a base of 0·02 sec.—**Nicolas de Kolossowsky**: The specific heats of a sufficiently cooled non-condensed phase.—**Pierre Jolibois** and **Pierre Montagne**: A graphical method of calculation of the energy yield of homogeneous reactions.—**Paul Riou** and **Paul Cartier**: The influence of some organic substances on the velocity of absorption of carbon dioxide by solutions of neutral sodium carbonate. The viscosities of the sodium carbonate solutions were increased by addition of glycerol, dextrose, and saccharose. Tabulated results are given shewing the velocities of gas absorption per square centimetre of absorbing surface and the corresponding viscosities.—**A. Boutaric** and **Mlle. M. Dupin**: The existence of two zones of instability in the flocculation of ferric hydroxide sols by electrolytes with polyvalent cations.—**Eugène Fouard**: A general method of preparation of metallic colloids. The method requires a colloid (starch, gelatine, albumen) completely freed from associated metallic salts, and an electrical method for carrying out this purification is described. In an aqueous solution of such a purified colloid a metallic salt is dissolved, and this is electrolysed between two insoluble electrodes with a current of a few milliamperes. A colloidal solution of the metal is formed round the cathode. The method has been successfully applied to a large number of metals, including mercury, lead, bismuth, copper, and antimony, and also to arsenic, iodine, and tellurium.—**G. Denigès**: A new method for the volumetric estimation of molybdenum. The method is based on the reduction to Mo_3O_8 by aluminium foil in sulphuric acid solution, followed by titration with permanganate.—**Max** and **Michel Polonovski**: A new method for the transformation of the tertiary heterocyclic bases into secondary dealkylated bases.—**Clément Duval**: A cobaltiboroammine. The preparation of a new ammine is described: analysis showed it to be $CoBO_3(NH_3)_3$. It is insoluble in water and very stable.—**A. Wahl** and **G. Vermeylen**: A new transposition in the naphthylamine sulphonic acids.—**L. Eblé**: The periodic deviations from the vertical at Paris. An analysis of the results obtained with the horizontal pendulum at the Paris Observatory over a period of 31 months.—**V. Vincent**: The measurement of the ionimetric acidity by the inversion of saccharose. Application to complex media: sols.—**C. Motas**: Hydracarus of the genus Megapus in the Dauphiné Alps.—**A. Labriet** and **R. Husson**: Experimental analysis and synthesis explaining the passages of the singing voice in the theory of vocal accord.—**A. Mordvilko**: The biology of the Phylloxera of the vine. The conditions of its subterranean life. The influence of climate.—**Marcel Abeloos**: The speed of regeneration of the head in *Planaria gonocephala*. The influence of the level of the sections.—**P. E. Pinoy** and **A. Nanta**: The frequent existence of a mycosis of the spleen in Algeria. The pseudo-cysts causing enlarged spleen in Algeria are due to a fungus similar to *Sterigmatocystis nidulans*, cultures of which have been obtained. The fungus penetrating the spleen introduces bacteria causing a secondary infection, and it is possible that the nature of the associated bacteria may modify the clinical type of the disease.

Vienna.

Academy of Sciences, Jan. 13.—**O. Wettstein**: Five new European mammals, species of Pitymys from Croatia and Tyrol.—**L. Walmann**: Report on the geological survey of the Moravian primitive rocks in Lower Austria.—**H. Leng**: Adsorption experiments on glasses and filtration materials by the methods of radio-active indicators. Adsorption on glasses approaches saturation.—**M. Holly**: (1) A new subspecies of silurid from Kamerun; (2) a new species of cyprinid from the islands of Little Sunda.—**L. Kober**: The geology of the Salzkammergut.—**A. Tauber**: Integration of linear differential equations.

Jan. 20.—**F. Wessely** and **M. John**: Researches on a-amino-N-carbonic acid anhydride.—**K. Przibram**: The coloration of compressed rock-salt under Becquerel radiation.

Diary of Societies.

SATURDAY, March 19.

British Mycological Society (London Meeting) (in Botanical Department, University College), at 11 a.m.—W. R. I. Cook: Influence of Environment on Infection by *Ligniera Junci*.—E. H. Ellis: Fungi in Japanese Carvings.—E. W. Fenton: Seed Mixtures and the Incidence of Fungal Diseases.—Miss M. P. Hall: Zoning in Cultures of *Monilia fructigena*.—K. R. Mohendra: Varieties in *Sphaeropsis malorum*.—J. Ramsbottom: Fragmenta Mycologica VII.

Geologists' Association (in Department of Anatomy, University College), at 2.30.—Prof. G. Elliot Smith: Demonstration of Fossil Remains of Man.

Association of Mining Electrical Engineers (North of England Branch), at 3.—C. D. le Maistre: Standardisation of Colliery Electrical Requisites.

Physiological Society (at University College) (Annual General Meeting), at 3.—K. H. Coward and Dr J. H. Burn: Variations in Response of Different Rats and Mice to Injections of Oestrin.—A. W. Bourne and Dr. J. H. Burn: (*a*) The Dosage of Pituitary Extract in Labour; (*b*) The Value in Labour of the Different Constituents of Ergot.—I. de Burgh Daly: Blood Flow during Respiration: The Influence of the Heart and of the Lungs.—Prof. J. Mellanby: The Preparation of Fibrinogen and Fibrin Ferment from Oxalated Ox Blood.—Grace Briscoe: Graded Muscular Contractions of Natural Form Produced by Electrical Stimulation.—F. R. Winton: The Action of Squill Extracts on Rats.—I. T. Zeckwer: The Hyperglycæmic Response to Bacterial Vaccines.—Dr. F. W. R. Brambell: The Maturation of the Graafian Follicle in relation to Oestrus.—Dr. E. B. Verney: Some Acute Effects of Pituitary Removal in the Dog.—E. Ponder: The Reflex Act of Blinking.—W. P. Blount: The Blinking Reflex in Animals.—A. C. Hampson and M. Maizels: The Effect of *p*H on the Distribution of Phosphorus between Human Red Cells and Potassium Phosphate Solutions.—Demonstrations:—An Apparatus for Propelling Air round Small Enclosed Circuits when Leakage to CO_2 is to be Entirely Avoided, by F. M. Haines.—(*a*) Ovarian, Uterine, and Vaginal Changes during the Oestrous Cycle of the Mouse; (*b*) X-ray Sterilisation of the Mouse Ovary, by Drs. A. S. Parkes and F. W. R. Brambell.—The Respiratory Quotient of the Heart, by L. E. Bayliss, E. A. Muller, and Prof. E. H. Starling.—The Oxygen Usage of the Kidney, by A. Fee, A. Hemingway, and Prof. E. H. Starling.—A Stimulating Chamber for Plain Muscle, by F. R. Winton.—A Colorimetric Method for Roughly Controlling the CO Tension in Respiratory Gases, by L. M. Pickford and Dr. E. B. Verney.—(*a*) An Apparatus for Continuous Reading of E.M.F.; (*b*) A Photo-electrolytic Effect, by Dr. D. T. Harris.—An Improved Perimeter, by B. Lang.—The Histological Appearances of the Pituitary after Different Amounts of Insulin, by Elizabeth C. Eaves.

Royal Institution of Great Britain, at 3.—Sir Ernest Rutherford: The Alpha Rays and their Application to Atomic Structure.

MONDAY, March 21.

Victoria Institute at Central Buildings, Westminster), at 4.30.—Rev. A. H. Finn: The Predictive Element in Holy Scripture.

Royal College of Surgeons of England, at 5.—Dr. A. Piney: Hyperplasia and Neoplasia in Lymphatic Tissue.

Institution of Electrical Engineers (Informal Meeting), at 7.—R. J. Mitchell and others: Discussion on Domestic Electrical Refrigeration.

Institution of Electrical Engineers (Mersey and North Wales (Liverpool) Centre) (at Liverpool University), at 7.

Institution of Electrical Engineers (Tees-Side Sub-Centre) (at Cleveland Technical Institute, Middlesbrough), at 7.

Institution of Automobile Engineers (Glasgow Centre) (at Royal Technical College, Glasgow), at 7.30.—H. R. Ricardo: Some Notes on Petrol-Engine Development.

Railway Club (at 25 Tothill Street, S.W.), at 7.30.—W. N. R. J. Back: The late History of the Great Northern Railway.

Aristotelian Society (at University of London Club), at 8.—G. Cator and C. E. M. Joad: Error (Symposium).

Royal Society of Arts, at 8.—G. I. Finch: Some Applications of Electrothermics (Cantor Lectures) (V).

Royal Geographical Society (at Æolian Hall), at 8.30.—J. M. Wordie: The Cambridge Expedition to East Greenland.

Chemical Industry Club.

TUESDAY, March 22.

Manchester Literary and Philosophical Society, at 4.—Prof. J. Barcroft: Physiology of Life in the High Andes (Wilde Memorial Lecture).

Royal Dublin Society (at Ball's Bridge, Dublin), at 4.15.—L. B. Smyth: On the Index Fossil of the Cleistopora Zone.—Miss Dorothy Beckett: The Influence of Separation and Pasteurisation on the Size of Fat Globules.—Exhibition by Dr. H. H. Poole of a convenient method of Charging Electroscopes.

Royal Society of Medicine (Medicine, Diseases in Children, and Dermatology Sections), at 5.—Dr. S. E. Dore, J. H. Sequeira, Dr. A. Eidinow, and others: Special Joint Discussion: The Uses and Limitations of Ultra-violet Light Therapy.

Royal College of Physicians of London, at 5.—Sir Charlton Briscoe: The Muscular Mechanism of Respiration and its Disorders (Lumleian Lectures) (1).

Royal Institution of Great Britain, at 5.15.—Dr. G. Shearer: X-rays and the Chemical Molecule (2).

Institution of Petroleum Technologists (Annual General Meeting) (at Royal Society of Arts), at 5.30

Zoological Society of London, at 5.30.—Secretary: Report on the Additions to the Society's Menagerie during the month of February 1927.—G. C. Robson: Seasonal and Sexual Dimorphism in the Squid *Alloteuthis subulata*.—Daphne Atkins: Report on the Myzostomida collected by Mr. F. A. Potts in Torres Strait, together with a Description of a Species obtained by Prof. J. Stanley Gardiner from the Maldives.—Oldfield Thomas: On Mammals from the Gobabis District of Eastern Damaraland, South-west Africa, obtained during Capt. Shortridge's Fourth Percy Sladen and Kaffrarian Museum Expedition. With Field-notes by the Collector.—Dr. F. P. Stowell and V. P. Clancey: Microscopical and Bacteriological Investigation of the Water in the Society's Aquarium.

Institution of Civil Engineers, at 6.—Prof. W. E. Dalby: Heat Transmission and the Motor-Car Radiator.

Institution of Aeronautical Engineers (at 30 Victoria Street), at 6.30.—L. A. Wingfield: Aircraft Law

Illuminating Engineering Society (at Lighting Service Bureau, 15 Savoy Street, W.C.), at 6.30.—L. M. Tye, W. Millner, H. H. Long, C. A. Hughes, and others: Discussion on Various Problems in Illumination and Practical Solutions.

Institution of Electrical Engineers (East Midland Sub-Centre) (at Derby Technical College), at 6.45.—G. H. Lake: Powdered Fuel.

Society of Chemical Industry (South Wales Section) (Annual Meeting) (at Technical College, Cardiff), at 7.

Institution of Electrical Engineers (North-Western Centre) (at Engineers' Club, Manchester), at 7.—Col. E. Mercier: Notes on the 60,000-Volt Underground Network of the Union d'Electricité.

Institution of Electrical Engineers (North Midland Centre) (at Hotel Metropole, Leeds), at 7.

Institute of Metals (Birmingham Local Section) (jointly with Birmingham Metallurgical Society and Staffordshire Iron and Steel Institute) (at Engineers' Club, Birmingham), at 7.—W. T. Griffiths: Nickel-Iron and Related Alloys.

Royal Photographic Society of Great Britain (Scientific and Technical Group) (Annual General Meeting), at 7.—Dr. O. C. de C. Ellis: Flame.

Society of Chemical Industry (Birmingham and Midland Section) (at Birmingham University), at 7.15.—D. W. Parkes: The Removal and Recovery of Phenols from Ammonia Sulphate Still Effluents.

Royal Anthropological Institute, at 8.30.—I. Schapera: Native Chieftainship in South Africa.

WEDNESDAY, March 23.

Royal Society of Medicine (Psychiatry Section) (Pathological Meeting in Laboratory of Maudsley Hospital, Denmark Hill), at 4.30.

Geological Society of London, at 5.30.—E. S. Cobbold: The Stratigraphy and Geological Structure of the Cambrian Area of Comley (Shropshire)

Institution of Automobile Engineers (Manchester Centre) (at Engineers' Club, Manchester), at 7.—H. R. Ricardo: Some Notes on Petrol-Engine Development.

Electrical Association for Women (at E.L.M.A. Lighting Service Bureau, Strand), at 7.—Electric Power Appliances in the Home.

Royal Society of Arts, at 8.—C. S. Orwin: The Transition of Agriculture.

Eugenics Society (at Royal Society), at 8.30.—Dr. C. C. Hurst: The Mechanism of Heredity and Evolution.

British Psychological Society (Medical Section) (at 1 Wimpole Street).

THURSDAY, March 24.

Chemical Society (Annual General Meeting), at 4.—Prof. H. Brereton Baker: Experiments on Molecular Complexity (Presidential Address).—Presentation of the Longstaff Medal for 1927 to Prof. R. Robinson, and of the Harrison Memorial Prize for 1926 to Dr. C. R. Harington.

Royal Society, at 4.30.—Sybil Cooper, D. E. Denny-Brown, and Prof. C. S. Sherrington: Interaction between Ipsilateral Spinal Reflexes acting on the Flexor Muscles of the Hind-limb.—Dr. F. W. R. Brambell: The Development and Morphology of the Gonads of the Mouse. Part I. The Morphogenesis of the Indifferent Gonad and of the Ovary.—Dr. R. J. Ludford: The Golgi Apparatus in the Cells of Tissue Cultures.—C. E. Walker and Margaret Allen: The Nature of Golgi Bodies and other Cytoplasmic Structures appearing in Fixed Material.—Dr. W. S. Patton and E. Hindle: The Development of Chinese *Leishmania* in *Phlebotomus Major* var. *Chinensis* and *P. Sergenti*. var.—G. S. Sansom: The Giant Cells in the Placenta of the Rabbit.

Royal College of Physicians of London, at 5.—Sir Charlton Briscoe: The Muscular Mechanism of Respiration and its Disorders (Lumleian Lectures) (2).

Royal Institution of Great Britain, at 5.15.—J. Guild: Colour Measurement and Standardisation (2).

Royal Aeronautical Society (at Royal Society of Arts), at 6.30.—Major M. Wronsky: German Commercial Air Development.

South London Entomological and Natural History Society, at 7.

Institute of Chemistry (Edinburgh and East of Scotland Section, jointly with same Section of Society of Chemical Industry) (at North British Station Hotel, Edinburgh), at 8.—A. M. Cameron: Fire Risks in Industry.

FRIDAY, March 25.

Physical Society of London (at Imperial College of Science), at 5.—Dr. E. Mallett: Acoustical Experiments with a Mechanical Vibrator.—Dr. E. T. Paris: The Stationary Wave Method of Measuring Sound Absorption at Normal Incidence.—J. H. Awbery and Dr. Ezer Griffiths: A Ball and Tube Flowmeter suitable for Pressure Circuits.—Demonstration of the Astrolabe and some other Medieval Surveying and Navigational Instruments, by Dr. A. Ferguson.

Institution of Mechanical Engineers (jointly with Society of Chemical Industry, Chemical Engineering Group), at 5.15.—Dr. W. R. Ormandy: Lubrication.

North-East Coast Institution of Engineers and Shipbuilders (at Newcastle-upon-Tyne), at 6.—Sir Richard Glazebrook: Pure Science: the Service it has already rendered to Engineering, and a Review of Modern Developments and their Possible Future Application.

Society of Chemical Industry (Glasgow Section) (jointly with Institute of Chemistry, Glasgow Section) (at 36 Buchanan Street, Glasgow), at 6.30.

Royal Photographic Society of Great Britain, at 7.—H. J. Bedford: Pocket Cameras and what can be done with them.

Institution of Engineering Inspection (at Royal Society of Arts), at 7.30.—Major H. Myers: The Educative Influence of Aircraft Inspection.

Junior Institution of Engineers, at 7.30.—S. R. Broderick: Notes on the Construction and Plant of the New Filtered Water Installation for the Seville Waterworks Company.

Royal Institution of Great Britain, at 9.—Prof. C. T. R. Wilson: Thunderclouds.

Manchester Literary and Philosophical Society (Chemical Section).

SATURDAY, March 26.

Geologists' Association (at Museum of Practical Geology), at 2.30.—Demonstrations:—Fossil Plants from the Coal Measures, by Dr. R. Crookall.—Goniatite Zones of the Millstone Grit of Central Lancashire, by S. W. Hester.—Fossils from the Neighbourhood of Leighton Buzzard, by J. Pringle.

Royal Institution of Great Britain, at 3.—Sir Ernest Rutherford: The Alpha Rays and their Application to Atomic Structure (2).

North of England Institute of Mining and Mechanical Engineers (at Neville Hall, Newcastle-upon-Tyne), at 3.—R. White: The Ventilation of a Pyrites Mine, with special reference to Fire-fighting, Safety and Rescue-work.

PUBLIC LECTURES.

SATURDAY, March 19

Horniman Museum (Forest Hill), at 3.30.—H. N. Milligan: Animal Growth and Evolution.

SUNDAY, March 20.

Guildhouse (Eccleston Square), at 3.30.—Address on One of the World's Beliefs.

TUESDAY, March 22.

Bedford College for Women, at 5.15.—Prof. E. T. Whittaker: Present Conceptions of the Cosmos.

THURSDAY, March 24

Fulham Central Public Library, at 8.—W. H. Hempsall: The Wonders of the Bee-Hive.

SATURDAY, March 26.

Horniman Museum (Forest Hill), at 3.30.—M. A. Phillips: Wild Life in Meadow, Stream, and Wood.

SUNDAY, March 27.

Guildhouse (Eccleston Square), at 3.30.—Very Rev. Dr. J. H. Hertz (Chief Rabbi): Fundamental Ideals and Proclamations of Judaism.

CELEBRATION.

March 18 to 20.

Mathematical Association (Yorkshire Branch) (at Grantham).—The Two-Hundredth Anniversary of the Death of Sir Isaac Newton.

March 19, at 10 A.M.—Bicentenary Scientific Meeting in the Old School, King's School, Grantham, with addresses by:—

- Sir J. J. Thomson: Newton's Work in Physics.
- Sir F. Dyson: Newton's Work in Astronomy.
- Dr. H. Lamb: Newton's Work in Mechanics.
- Prof. G. H. Hardy: Newton's Work in Pure Mathematics.
- Dr. J. H. Jeans will preside and give an address on Isaac Newton.

At 2.—Pilgrimage to Woolsthorpe Manor House (Newton's birth-place) and visit to Stoke Rochford, where Mr. C. Turnor will speak on Newton's Countryside.—At 7.30.—Celebration Dinner at the George Hotel, Grantham. Chairman: Sir J. J. Thomson. Speakers: Prof. H. H. Turner, Prof. E. T. Whittaker, the Bishop of Birmingham, and the Bishop of Lincoln.

March 20, at 11.15 A.M.—Bicentenary Service at the Parish Church, Grantham. Preacher—The Bishop of Birmingham.

CONFERENCE.

Tuesday, March 22.

Rothamsted Experimental Station, Harpenden, at 11.30 A.M.—Conference on Cultivation: What the Farmer aims at and how he does it. Chairman: Lord Bledisloe.

- H. Drewitt: Cultivation on the West Sussex Chalk and Brick Earth.
- J. Joyce: Spring Cultivation in Western England.
- J. H. Spilman: Cultivation Operations on the Yorkshire Wolds
- J. Steel: Spring Cultivation in an Eastern County.
- Dr. B. A. Keen: Cultivation: The Art and the Science.

CONGRESSES.

April 20 to 24.

Journées Médicales Marseillaises et Coloniales (at Marseilles).—Prof. Cantacuzène: The Rôle of the Streptococcus in the Etiology of Scarlet Fever.—Dr. Mayer: Recent Advances in the Treatment of Cancer.—Prof. Ottolenghi: Malaria.—Dr. N. Bernard: Beri-beri.—Prof. Imbert: Bone-grafting.

April 25 to 28.

German Society for Internal Medicine (at Wiesbaden).—Discussions on Psychotherapy, introduced by Gaupp and Fleischmann; Results of Recent Functional Investigations of the Stomach and Duodenum, introduced by G. Katsch.—A joint meeting with the German Rontgen Society will be held on April 26, with a discussion on the Significance of Rontgen-ray Examination of the Lungs and Mediastinum for Internal Medicine (excluding Tuberculosis), introduced by Dietlen, Assmann, Haenisch and Lorey, and Fleischner.

SATURDAY, MARCH 26, 1927.

Science and Human Life.

DISCUSSIONS centring round the application of scientific knowledge to the solution of social problems result too often in generalisations which have no regard to the very different positions in which the physical, biological, and social sciences find themselves to-day. It is a commonplace to say that if science is to be of use, research must be entirely unhampered. Generally speaking, there is nowadays freedom of research in all branches of science, though it can scarcely be supposed that, in countries such as Russia, social scientists are wholly free to investigate the institution of private property and the system of private enterprise.

The situation of the physical, biological, and social sciences is thus much the same so far as pure research is concerned. When, however, we come to consider the application of scientific knowledge, the situation is very different in each case. Where research continues unhampered there arise from time to time opportunities of employing the results of research, and our attitude towards these possibilities may be either scientific or unscientific. By a scientific attitude is meant the realisation that what research has disclosed is merely a method of producing with a greater or less degree of certainty a particular result. Methods themselves are neither good nor bad. Questions of value do not arise at this point, but only when we go on to consider the effect of the employment of these methods upon those persons who use or are in any way touched by the methods. Methods of mass production either do or do not result in greater productivity. This is a problem preliminary to and wholly separate from the question of the moral effect of mass production upon the workers.

So far as the physical sciences are concerned, we are no longer in the mood to regard aeroplanes as 'unnatural' or flying as 'impious.' Here the scientific attitude is in fact general. The social sciences stand at the opposite pole and there is as yet little sign of the emergence of the scientific attitude. Divorce, nationalisation, and capitalism are held to be good or bad in themselves; they may be worshipped or regarded as the evil one barely if at all disguised. The biological sciences occupy a midway position. Prof. Julian Huxley,[1] in his lecture on "Biology and Human Life" delivered before the British Science Guild on

---

[1] Biology and Human Life. Norman Lockyer Lecture, 1926, by Prof. J. S. Huxley. (London: British Science Guild, 1926.) 1s

Nov. 22 last, discusses the use of the results of biological research in relation to health, quantity, and quality of population. The consideration of health raises the question of the use of vaccines, of the quantity of population that of contraceptive methods, of the quality of population that of controlled breeding.

No one at all well acquainted with popular discussions of these matters could claim that the scientific attitude is predominant. It is probably growing. It does not, however, seem to be more prominent in certain of the groups, social, religious, or political, into which the population is divided than in others. People regarded by others or regarding themselves as possessing 'advanced' views do not seem to be remarkable for their scientific outlook as defined here. A recognised leader of advanced political thought recently described inoculation as 'unclean.' This is equivalent to thinking that the taking of a census is a wicked act displeasing to Providence, and likely to be visited by an 'epidemical distemper,' as widely held in the eighteenth century. There are passages in Mr. H. G. Wells's "World of William Clissold" which suggest that he regarded birth control as an excellent thing in itself—precisely the same error the other way round.

Just as it cannot be said that people of certain religious views or of particular political opinions are more scientific than others in their attitude to the possible use of the results of research, so it does not appear that men of science as a whole are especially remarkable for their power of distinguishing between the efficiency of methods and the reactions upon moral conduct of the employment of the same methods. They are apt to think that because a method is effective it is therefore good.

This statement cannot, however, be made of Prof. Huxley. He does advocate, it is true, the use of contraceptive methods and the control of breeding, but he sees that he must justify his advocacy not merely by observing that problems of the quantity and quality of population present themselves which these methods might solve, but also by a demonstration, so far as it can be given, that the moral effects would be good. It does not seem, in fact, to be difficult to build up a case to show that few scientific methods have ever offered so much opportunity for the unselfish regard for the welfare of others as those which permit us to regulate numbers—which is a necessary precedent to a life of decency in any community—and to go some way at least towards ensuring that the next generation shall begin life reasonably well endowed with all that makes possible a full and useful existence.

It is thus of primary importance that if, as Prof. Huxley desires, use is to be made of our rapidly increasing biological knowledge, what has here been described as the scientific attitude towards the application of the results of research should become more widespread. It cannot be too strongly urged that those who press upon the public the use of contraceptive methods as admirable in themselves are just as reactionary as their opponents.

If we now leave this point and pass on to consider the knowledge available for dealing with the problems of quantity and quality of population, it is evident that we are better informed regarding methods of controlling quantity than of controlling quality. It is true that much remains to be done in the way of investigating the precise efficacy and incidental results of methods of controlling quantity. But the problem is of far less magnitude than that of quality. Progress can be made by independent research workers, which is by no means the case in some of the most important aspects of the quality problem.

If we are to have adequate methods of dealing with the quality problem, research must be prosecuted in four distinct fields. There is first the problem of the mechanism of heredity, and secondly that of the mode of inheritance of human character. These are problems which the independent investigator can attack. It is unnecessary to refer here to the amazing developments in our knowledge of the mechanism of heredity, which appears to be essentially of the same nature in all organisms. Progress in the second field is of necessity slow because of the impossibility of experiment. The research worker must make the best of such data as are available resulting from the uncontrolled matings of the human species. There is next the third field concerned with the distribution of inherited characters within the population, and the fourth concerned with the change in that distribution. We must know where certain qualities are to be found or, to put it in another way, how far social classes, occupational and economic groups, differ from one another now in respect to these inherited characters, and whether these differences are becoming greater or less.

Within these third and fourth fields the independent research worker is nearly powerless so far as the collection of data is concerned. A very little reflection will show that the efforts of independent research workers can never alone be expected satisfactorily to elucidate the position. It would be as reasonable to expect the unaided efforts of research workers in economics to obtain a satisfactory review of the trade or income of the country without recourse to government figures of imports, exports, and income tax, as to expect biologists by their own unaided efforts to give us at all full information as to the genetic composition of the population. It follows that adequate guidance cannot be given, even if the will to use it is there, unless government machinery can be set in motion to collect the data. If we have to wait for a government of this degree of enlightenment, a bleak prospect opens out. But encouragement may be obtained if we refer again to the economists. Income statistics are not collected because an enlightened government wishes to keep a watch upon the national income, but because a hard-pressed government has to find money. Economists have to use these data, inadequate as they are, for their own purposes.

There is similarly a possibility of the use by biologists of government data regarding the medical inspection of school children and of official data from the census, for the purpose of elucidating in some detail our biological heritage and the changes which are taking place. The difficulties at present are great, but government machinery exists which, if slightly adapted for this other purpose, would allow an examination to be made of the position and a watch to be kept of changes at least from decade to decade. The most urgent needs are that the medical examination of school children should be standardised in order that the data could be aggregated and the results of one year compared with those of another, and that the questions asked in the census of 1911, which rendered an inquiry into differential fertility possible, be made a permanent feature of the census. At the present time, we can do little more than guess what the position is.

The community must be brought to learn that there is no more fruitful use of communal resources than when applied to keeping a watch upon the biological inheritance of the community. It may or may not be desirable for us to copy Sweden, where a State Institute for Race-Biology has been founded for this purpose. But until ways of accumulating the necessary knowledge are found, we shall not be in a position to take effective steps, as Prof. Huxley desires, to "weed the garden of humanity."

A. M. C.-S.

Research in Historical Chemistry.

Studien zur Geschichte der Chemie. Festgabe Edmund O. v. Lippmann zum siebzigsten Geburtstage. Dargebracht aus nah und fern und im Auftrage der Deutschen Gesellschaft für Geschichte der Medizin und der Naturwissenschaften herausgegeben von Julius Ruska. Pp. vi + 242. (Berlin: Julius Springer, 1927.) 19·50 gold marks.

THE cause of research in historical chemistry owes much to the work and influence of two men: Marcelin Berthelot in France, and Edmund O. von Lippmann in Germany. It is an interesting coincidence that the approaching celebration, in October next, of the centenary of Berthelot's birth should follow so closely upon a public recognition of von Lippmann's activities in the common field of these two eminent chemists and chemical historians. At the recent jubilee of the Deutsche Gesellschaft für Geschichte der Medizin und der Naturwissenschaften, von Lippmann was awarded the Sudhoff medal for his researches in historical chemistry; the volume under review has now been issued under the auspices of the same society to mark the seventieth birthday of one whom Ruska acclaims in an eloquent dedication as "Meister und Führer" in this field.

It is to be remarked with regret that the volume contains neither a biographical notice of the doyen of chemical historians nor a discussion of his work and its influence on the progress of historical chemistry. Von Lippmann's industry and versatility may be gauged, however, from the accompanying list of 18 books and 159 original papers, etc., published by him since 1878. Among the more familiar book titles are "Geschichte des Zuckers," "Die Chemie der Zuckerarten," "Entstehung und Ausbreitung der Alchemie," and "Zeittafeln zur Geschichte der organischen Chemie"; while the papers contain historical references to such diverse subjects as sugar, the thermometer, aluminium, gunpowder, alchemical poetry, the Ebers papyrus, distillation, alcohol, Petrarch on alchemy, the use of petroleum in the Middle Ages, the name 'Berzelius,' chemistry and technology in Herodotus and in Dante, and so forth.

Apart from the items which have been mentioned, the book consists of a series of twenty-two essays by acknowledged authorities on subjects of special interest in historical chemistry. The contributions, which are arranged chronologically, touch upon the development of chemistry from the Babylonian era, through the Greek and Islamic periods, down to the present day. The collection conveys a striking impression of the vigorous growth of research in historical chemistry during recent years, particularly in Germany. Some of the papers attain a high level of scholarship, but it is not possible here to do more than comment upon a few points of outstanding importance or interest.

Darmstaedter (Munich), in a paper on the *lapis lazuli*, indicates that the great mythological significance of this stone in the Babylonian-Assyrian civilisation led to the production, by a carefully guarded process, of an artificial stone containing small quantities of copper and cobalt. Hopkins (Amherst, Mass.) endeavours to base a comprehensive explanation of early alchemical work upon a philosophy of colour, the trend of his argument being illustrated by such quotations as the following: "Cast a sulphur preparation upon silver to get gold" (pseudo-Democritus); "It is the tinctorial principle which causes the vapour to develop the gold" (Zosimus); "Mare tingerem si mercurius esset" (pseudo-Lully). It may be objected that colour was only one of many qualities, regarded in the Aristotelian sense as accidental, and that even the early alchemists knew gold when they encountered it. The sweeping claim that all alchemical practice was based upon an unvarying sequence of colours also invites criticism.

The most important contributions to this work are those dealing with Islamic chemistry. Wiedemann (Erlangen) directs attention to what is perhaps the first mention of magnetic polarity. Ibn 'Abd al-Raḥîm, quoted by Al-Jildakî, refers to a four-sided stone which was capable of attracting or repelling a certain piece of (magnetised) iron when presented to it in different ways. It may be noted that Petrus Peregrinus, of Picardy, made a similar observation in the thirteenth century.

The volume contains two contributions to the Jâbir (Geber) problem which are undoubtedly of first-class importance. It may be recalled that about two years ago Darmstaedter discovered a Latin version of Jâbir's "Book of Mercy"; Ruska (Heidelberg) now records the recent discovery in Egypt by Meyerhof of a large portion of the Arabic text of Jâbir's *Liber LXX.*, and gives a preliminary survey of the contents of this "unvergleichlich kostbaren Fund." For the second time within two years Latin and Arabic texts of Jâbir have been brought together, and such remarkable successes should encourage the enthusiastic band of investigators in this field to prosecute with redoubled ardour their search for the Arabic originals of the *Summa perfectionis* and other works of the central figure of Muslim chemistry.

"What Aristotle was for philosophers, Jâbir was for chemists," writes Holmyard (Bristol) in the sole British contribution to the volume under notice, "and a full investigation of his life and writings would unquestionably be of the utmost value for the history of chemistry." Holmyard now adduces important new evidence from Al-Dînawarî's Kitâbu'l-Akhbâr al-Ṭiwâl (Book of Lengthy Narratives), which, although handled with commendable restraint, will probably be accepted generally as providing a satisfactory settlement of the difficult questions of Jâbir's birth, parentage, nationality, and date. The evidence indicates that Jâbir was the son of a certain Arab Shî'ite known as 'Ḥayyân the druggist,' and that he was born at Ṭûs about A.D. 721–722, during his father's presence in Khurâsân on a political mission for the 'Abbâsids. A further elucidation of Jâbir's relations with the Barmakides and with Ja'far al-Ṣâdiq provides an apparently effective refutation of Ruska's contention that the Jâbir-Ja'far connexion was a myth. Students of this period will welcome the promised publication, by Geuthner of Paris, of a complete edition of Jâbir's Arabic works, accompanied by English translations.

Other articles deal with subjects of such general interest as chemical symbols (Walden, Rostock), Priestley's defence of the doctrine of phlogiston after his removal to America (Davis, Cambridge, Mass.), chemical instruction in the German universities in the first quarter of the nineteenth century (Lockemann, Berlin), and the Goethe-Wackenroder correspondence (Brauer, Cassel). The series concludes with an entertaining chemical potpourri by Speter (Wehlen). Those readers who are conversant with the efforts of William Barnes, the Dorset poet, to redistil the waters from 'the well of English undefiled,' will take particular interest in the suggestions for 'purified' German chemical terms; but though the puristic inorganic chemist might conceivably prefer "Sauerstoff" to "oxygen," his faith would need to be greater than a grain of mustard seed if it permitted him to accept for himself the designation "Nicht-Kohlenstoffverbindungsscheidekünstler"!

The book is well printed, and it contains an excellent frontispiece portrait of von Lippmann. It will be found both interesting and useful by all chemists who have developed that lamentably rare sense of historical continuity with the past which is so desirable in the teaching and study of science.

John Read.

Books and a Superlative.

The Best Books: a Reader's Guide to the Choice of the best available Books in every Department of Science, Art, and Literature, with the Dates of the first and last Editions, and the Price, Size, and Publisher's Name (both English and American) of each Book: a Contribution towards Systematic Bibliography. By William Swan Sonnenschein. With complete Authors and Subjects Index. Third edition, entirely rewritten. Part 4. Pp. 1681-2510. (London: George Routledge and Sons, Ltd., n.d.) 36*s*. net.

DESPITE any criticism of detail, this is a work indispensable to all persons for whom books are practical tools. This volume will have a special appeal to readers of NATURE; although it includes the classes of science, art, music, drama, domestic arts, and sports, three-quarters of the volume (which contains pp. 1681-2510 of the complete work) come under the heading of science.

Actually, however, this heading is used somewhat unscientifically, because it includes all industries and trades as well as the pure sciences. Also at first sight one is somewhat surprised to find here such headings as immortality, Christian science, industrial and economic history. The explanation is largely that the producers of the work have boldly faced the difficulty that the earlier volumes are tending to be out-of-date before the last volumes are completed.

As a corrective, wherever possible they have included 'additions' to the bibliographies of the subjects of the earlier volumes, and these 'additions' have been tacked on to more or less cognate subjects in the present volume, convenience being the controlling factor rather than a strict adherence to a scientific arrangement of topics.

This method has not been wholly disadvantageous. Besides affording probably the best means of bringing the earlier volumes up-to-date, it now gives us psychology in all its aspects as a branch of science. At its original place under philosophy its housing was somewhat old-fashioned; for psychology now passes from the speculative domains of philosophy into documented and precise methods of handling such as allow it to be regarded as a science proper.

We have tested the volume in some dozens of instances, and only exceptionally has it failed to produce the entry expected. One instance was "Population," by H. C. Wright, which was worth inclusion as a simple, clear, and inexpensive statement of the mildly-pessimistic attitude of the Cambridge school on the population question; another was "A Hillside View of Industrial History: a Study of Industrial Evolution in the Pennine Highlands," by A. Newell. This book, on account of its original investigations, was well worth inclusion in the 'additions' to industrial and economic history now given in this volume under arts and trades to supplement the treatment of the subject under earlier headings. The latter case, however, is not quite a fair test, because the book was published somewhat obscurely in Todmorden; although, in fact, it received favourable critiques through the usual channels. That a compilation should fail only in such points as this over a large number of tests, especially when allowance is made for differences of opinion as to what the 'best books' really are, shows the thoroughness with which the ground has been covered.

After all, however, the 'best book' is only best in relation to the purpose for which it is either intended or used. We are only half on our way towards selection when we get a list of 'best books' on a given topic, if that list includes all the best books without some attempt, if not at evaluation, at least at a comment on the point of view presented. Wright's book mentioned above is a good illustration. Some little evaluation is attempted in "The Best Books" by the use of an asterisk to indicate any work of outstanding importance. This mark of pre-eminence is, quite rightly, very sparingly used, and it is supplemented in a very small minority of examples by some brief evaluatory or explanatory comment. One would like to see the latter idea carried much further, but it would be a gigantic additional task to impose on the shoulders of the present compilers; this latest volume would probably have followed its predecessor at an interval of thirteen years instead of three years. In additional excuse, this work was a War casualty. The new edition was begun in 1910, the second volume appeared in 1912, the third in 1923, and now the fourth is published in 1926. But this latest volume shows a vitality unaffected by the passage of years, or by the happenings often inevitably associated with the production of a work over so long a period; for the ranks of its compilers have not been unaffected by the limitations of human mortality.

Such small additional points of criticism as occur would deal with the age of many books here noted and the consequent difficulty of obtaining them by purchase. Particularly is this the case in architecture, from which list one misses Aldin's "Old Manor Houses," but it is true that these books are nevertheless standard books.

This is a great work, unsurpassed in its scope or accuracy by any similar work in any other country. It now appeals almost pathetically for its index volume to make it fully usable, although there is an excellent system of cross-references between correlative topics. But could not some more straightforward notation be used than one which refers the inquirer to H § 47.* * * * * * ?

C. R. S.

Science and the Humanities.

Plant Nutrition and Crop Production. By E. J. Russell. Pp. ix+115+21 plates. (Berkeley: University of California Press; London: Cambridge University Press, 1926.) 12*s.* 6*d.* net.

In a recent review in these columns of a Stationery Office publication—"Research and the Land" (Dec. 4, 1926)—attention was directed to the dangers that research workers encounter when they enter the journalistic field, a danger picturesquely expressed in the Scots' proverb that —"fules and bairns shouldna see half-dune wark." The book before us (in part an excursion in that field) is the text of a series of lectures delivered at San Francisco under the provision of the Hitchcock Trust, of which the object and purpose appear to be publicity, not (we hasten to add) in the form of belauding any one person or institution, but with the dignified purpose of creating public confidence in scientific methods and ideals generally.

The task before the lecturer in this instance has been performed with great ability. We have here succinctly expressed a complete review of the whole history of scientific research on plant nutrition from the agricultural aspect, finishing up with some account of the more recent work on the subject at Rothamsted and elsewhere. The profuse and picturesque illustrations of this book, a selection, no doubt, from the lantern-slides displayed, are of unusual interest. From a literary point of view, too, the text is excellent. Few, if any, agricultural writers can surpass Sir John Russell in his shining enthusiasm for the humanistic value of scientific pursuits, the limitations of which never daunt him. "Exact knowledge," he says, "is the only sure basis for improvements: encourage, therefore, those among you who are striving to win it. Their task is slow, painful, and often disappointing . . . knowledge is but an approximation to a truth never to be wholly attained by man."

This, however, should be a review, not a panegyric; and one is bound to question whether enthusiasm based, as it may be, on personal achievement, may not obscure clear vision of the field as a whole as it appears to those primarily interested in the practical application of scientific results. What, for example, has the agronomist to say to all this? For it is upon *his* achievements that the popular support of scientific research in agriculture may depend, and, scientifically, are not the gaps in knowledge many and vital?

To the doubter, there can be only one answer. It may be true that half a century of agricultural research has not yielded an adequate harvest in the form of material return to the husbandman; but even the layman must hold to the faith that the only avenue to material improvement is increased knowledge. Long ago it was said . . . "*pater ipse colendi haud facilem esse viam voluit,*" and the way of the research worker is equally hard; but go the road, however hard it be, he must; if he fails to convert the common crowd to that faith, then, indeed, is the cause of applied science desperate. On this satisfying note our author aptly closes:

> . . . Man's the prerogative, knowledge once gained
> To ignore, find new knowledge to press for, to swerve
> In pursuit of, no! not for a moment: attained
> Why, onward through ignorance! Dare and deserve!
> As still to its asymptote speedeth the curve.

Our Bookshelf.

Matter and Gravity in Newton's Physical Philosophy: a Study in the Natural Philosophy of Newton's Time. By A. J. Snow. Pp. 256. (London: Oxford University Press, 1926.) 7*s.* 6*d.* net.

The explanatory title of this book, namely, "A Study in the Natural Philosophy of Newton's Time," gives a good indication of the scope and nature of the contents. It is certainly desirable in these days, when science, philosophy, and religion are all recognised as important contributors to the progress of human thought, to have such an outstanding period as that of the seventeenth century and early eighteenth surveyed, especially with reference to the atomic revival which, as the author points out, is very closely associated with the name of Pierre Gassendi. The work of Robert Boyle, and also the dispute between Gassendi's and Descartes' schools of atomism, are traced in the first chapter, and the question as to the divisibility of matter is shown to have formed an important phase of the intellectual background of Newton's time. Galileo's ideas with regard to movement are also traced, and so the way is prepared for the Newtonian atomism which is discussed in the second chapter.

The objections to Descartes are dealt with at length, and it is shown how that, to Newton, the idea of God was essential. The influence on Galileo is brought out in this chapter with regard to the theory of force.

In the third chapter, Newton's doctrine of gravity is treated, and throughout what follows, careful attention is paid to the question of action at a distance and ether. The controversy with Liebniz and the alleged 'occult powers' reveal the keen discussion in matters of natural philosophy which took place in the period under discussion. The 'active principles' of Newton receive careful treatment in this chapter, which closes with the mathematical theory of gravity.

The fourth chapter naturally deals with the metaphysical doctrine which Newton's theory suggests; attention is directed to the mystic influence of Jacob Boehme.

The last chapter discusses the relation of mathematics and physics to philosophy in general, and deals with the opposition which Newton's use of hypothesis met with in the polemic directed against him by the Cartesians. H. D. A.

Plato's American Republic. Done out of the Original by Douglas Woodruff. (To-day and To-morrow Series.) Pp. 122. (London: Kegan Paul and Co., Ltd.; New York: E. P. Dutton and Co., 1926.) 2*s.* 6*d.* net.

THIS delightful little book improves on a second reading. It is a mock Platonic dialogue—not pedantically close to the Greek—purporting to give Socrates' account of a lecture tour he has just taken in the United States, accompanied by Xantippe, who also lectures, with much more popular acceptance than her husband. The fun of the book runs fast, but is not furious. It is based on a subtle and penetrating but not unfriendly criticism of the prevalent mind in the United States. Much of it deals with familiar topics, Prohibition, card-indexes, the worship of numbers, facts and size, and, above all, of the new god 'Progress.' But it is all done more charmingly than we remember to have ever seen before, and it winds up with a companion picture of the mechanical and Philistine side of British civilisation. The remedy is to be found in the real education, on Greek lines, of young American women, who may be trusted afterwards to rule their husbands. The men are to be left for their own training to the discipline of football and baseball. The address of Socrates at the luncheon of the Rotarian Club in Hootsville is the gem of the book. He is finally shouted down when he urges that they "should do business" with the three weaving sisters of Greek mythology, Clotho, Lachesis, and Atropos with her dreaded shears. Did he not know, he was asked, that they in Hootsville, and everywhere else in the States, had machines which spun, measured, and cut thread in the single operation?

The concluding sentence of the book is typical of its combined seriousness and wit,—" For there are times when it is important to know the truth, and life is one of them." F. S. M.

Cement, Concrete and Bricks. By Alfred B. Searle. (Outlines of Industrial Chemistry.) Second edition. Pp. xi+441. (London: Constable and Co., Ltd., 1926.) 24*s.* net.

SOUND information about the materials named in the title of this book is badly wanted, and every effort to interpret the latest research work in a way which can be applied in practice should be welcomed. Mr. Searle in this new edition of his book directs attention to the work of Prof. Duff Abrams on the effect of the amount of mixing water in concrete. There is no doubt of the importance of this. The chapter on the chemistry of cements is much improved, but seems still rather overloaded with the work of W. and D. Asch.

There are, however, many statements in the book which are misleading. The description of a rotary kiln and the diagram on page 26 does not convey much impression of a modern plant. The statement on page 83 that the allowable limit of 2·75 per cent. for sulphur trioxide (SO_3) in Portland cement laid down by the British Engineering Standards Specification does not include the gypsum added to control the setting time, is incorrect. Again, the statement on page 111 that no standard specification for cements other than Portland has been issued by British Engineering Standards Association is incorrect. A standard specification for Portland Blastfurnace Cement was issued by this body in 1923 and revised in 1926.

The chapter on reinforced concrete is not helpful, and in many cases is misleading. It bears too much resemblance to a compilation from makers' catalogues. Much more work has been done on cement and concrete since the first edition of this book than has been noted in the revision, and it is regrettable that the work has not been brought up-to-date and the inaccuracies corrected.

Practical Hints to Scientific Travellers. Edited by Prof. H. A. Brouwer. Vol. 4. Pp. v+171+11 plates. (The Hague: Martinus Nijhoff, 1926.) 5 guilders.

A NOTICE of the first three volumes of this series appeared in NATURE, vol. 118, p. 44 (July 10, 1926); the fourth volume, now before us, deals with travel in Egypt, Angola, Australia, Antarctica, Venezuela, and Haiti. Doubtless the various articles are being published in the order in which they come to hand, but the result, in the case of the present volume, has been too miscellaneous a grouping. In any further edition of the whole work it would obviously be an improvement to redistribute the articles among the several volumes, in order to bring together those having some bearing on one another.

Like its predecessors, this volume is packed with useful and very much up-to-date information, although the sections on Venezuela and Haiti are short and scarcely enter into sufficient detail. In the section on Australia several pages are devoted to hints for botanical collecting, but most of the articles, being written by geologists, will probably be of especial help to members of geological expeditions. Prof. Griffith Taylor gives an interesting account of the experience gained by Capt. Scott's last antarctic expedition; his remarks should be very helpful when the preliminary arrangements are being made for any further expeditions to that part of the world. The illustrations in this book are well reproduced, and give a good idea of travelling conditions in the various regions.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Biological Fact and Theory.

"*Who is this that darkeneth counsel by words without knowledge?*" (Job xxxviii. 2).

Prof. J. S. Huxley (Nature, Mar. 5, p. 350) writes: "Prof. Walker says . . . that Dobell 'proved' that hereditary characters could not be controlled by chromosomes in certain Protozoa." What I did say is quite different. Here it is: "There is a number of organisms in which the distribution of the chromosomes is such that they could not possibly convey a Mendelian character." I did not use the word 'proved,' which Prof. Huxley places in inverted commas, from beginning to end of my letter.

He goes on to say, "The main reason advanced by Dobell concerned sex," and "if Prof. Walker had been better acquainted with genetical literature he would have remembered that almost simultaneously with Dobell's 'proof,' Wettstein was demonstrating experimentally, and conclusively, . . ."

Mr. Clifford Dobell in the paper referred to, having given a detailed description of the distribution of the chromosomes in certain organisms, begins his argument as follows: "Let us now select a particular character and a particular chromosome, and consider their relations to one another. It is really immaterial which character or which chromosome we take; but for the sake of argument let us take sex as the character to be studied."

Any one reading the paper will find that it was written with the object of confronting with actual facts certain sweeping generalisations of which Prof. Huxley so constantly provides us with examples. He will also see that sex has nothing to do with the argument. So far as I can see, Wettstein's work on mosses, which Prof. Huxley quotes but to which he gives no reference, has no direct bearing on the particular point at issue, and I must place his use of it in the same category as his misquotation of me and his misunderstanding of Mr. Dobell.

Referring to Prof. Johnstone and myself, Prof. Huxley says, "But has Liverpool never heard of Boveri's experiments on disperm sea-urchin eggs, published exactly twenty years ago?" This work was published too late for me to refer to it in my little book on cytology (1907), but Prof. Huxley will find sufficient evidence to show that I had read it in my "Hereditary Characters" (1910, Edward Arnold, London, pp. 37-8 and 222).

I would bring a remarkably apposite passage from another work to his notice.

"Now, from the purely artistic point of view, . . . I consider it an axiom that one should never appear to doubt that the other side has performed the elementary duty of acquiring proper elementary information, unless there is demonstrative evidence to the contrary" (Thomas H. Huxley, "Collected Essays," vol. 5, p. 373. Macmillan, London, 1909).

As, however, the main object of all of us is the ascertainment of truth, I must ask to be forgiven for wasting so much space on trivial self-justification and return to my protest against the constant presentation of doubtful theories as proven facts. I have watched the development of 'neo-Mendelism' from its inception. (Having regard to Prof. Huxley's methods of controversy I must be precise. I do not mean from the time of the first publication by Mendel in 1865, but from the time of the 'rediscovery' very many years later.) I have watched, often with amazement, sometimes with amusement, assumption piled upon assumption as occasion arose to make the 'neo-Mendelian' 'laws' agree with the results of breeding experiments. The attitude of Prof. Huxley and others of the same school seems to me to approximate to that of the advertiser who is convinced that the more often he repeats a statement the greater will be the number of people who will believe it. Out of the vast accumulation of assumptions has arisen the jargon in which Prof. Huxley sets forth what he claims to be a statement of the fundamentals of genetics. This statement of fundamentals represents, not proven facts, but assumptions for which a varying amount of evidence is available. May I be allowed one final quotation:

> The meaning doesn't matter if it's only idle chatter of a
> transcendental kind,
> And every one will say
> As you walk your mystic way,
> "If this young man expresses himself in words too deep
> for me,
> Why, what a very singularly deep young man this deep
> young man must be!"

(W. S. Gilbert, "Patience," Opéra Comique, 1881.)

Charles Walker.

The University, Liverpool, Mar. 8.

In Nature of Feb. 26, Prof. Johnstone asks the question, "Is breeding cats, and cocks and hens, and flies, and so on, such fundamental research?" He might equally well ask, "Is reading galvanometers, or making organic compounds, or cutting sections, or stimulating nerves, such fundamental research?" The answer is quite clear. These operations, like breeding animals, are part of the technique of research, which may or may not be fundamental in any given case. For example, cat-breeding was part of a fundamental research when it showed that the spermatozoon determined the sex of the young, and that some of the differences between the wild species (or sub-species) of cat were inherited in a Mendelian manner.

After admitting his inability to understand the results which geneticists have so far reached, Prof. Johnstone then proceeds to tell them their real function, which is to determine how genes grow. Here I would very respectfully beg leave to differ from him. To-day the atomic theory in genetics is about as well established as was the atomic theory in chemistry a hundred years ago. But for a century after Dalton chemists concerned themselves not quite unprofitably with the mutual relations of atoms, without knowing very much about their nature. This is what geneticists are now doing with regard to genes; and just as the internal structure of atoms was elucidated by physicists rather than chemists, it is probable that the inner nature of the gene is a problem for the biochemist rather than the geneticist.

Prof. Johnstone's second fundamental problem, of how the genes co-operate in development, is analogous to the problem of how atoms co-operate in a molecule. The most obvious preliminary to its solution is to combine genes in as many different ways as possible and see what happens; and this is just what the despised breeders of cats are doing, to the extent of their financial resources. If they are better than Prof. Johnstone at solving crossword puzzles it may be that they share this superiority with organic chemists and spectrum analysts. So perhaps they need not be altogether ashamed of their little accomplishment.

J. B. S. HALDANE.

Trinity College,
Cambridge, Mar. 3.

I SHARE Prof. Johnstone's inability to solve either crossword puzzles or Mendelian results (NATURE, Feb. 26, p. 319). But I do not think this should encourage him to decry the carrying out of breeding experiments by men who can properly interpret them. It seems reasonable to regard Drosophila as the sum of a number of factors arranged in a certain way, just as a crystal of alum is an aggregate of molecules orientated in a definite pattern, of atoms specifically arranged to give molecules, and of electrons to give atoms.

It is almost an axiom of scientific method that analysis must precede synthesis. The first stage toward the solution of the Drosophila problem, then, must of necessity be one of analysis; the splitting up of the entity Drosophila into genes and factors. This analysis is far from being complete yet. With the materials gained thereby we can proceed to the synthesis, namely: Why is this aggregate Drosophila, and not Pulex or Homo? An attempt to synthesise before the materials are available is as ineffectual as the attempt to make bricks without straw.

The problem Prof. Johnstone propounds is, however, the really fundamental one; and until we reach the stage of synthesis, Drosophila will not be allowed to retire into the oblivion it so well deserves.

Atmospheric Electricity.

DR. CHREE, in his review on the above subject (NATURE, Dec. 18, 1926, p. 894), has inadvertently drawn an erroneous inference with regard to the reduction factors used by Dr. Mauchly for the *Carnegie* potential-gradient observations. The manner of obtaining these factors is described by Messrs. Ault and Mauchly on pp. 207-209 of the volume (Researches, Department of Terrestrial Magnetism, vol. 5) reviewed, and it is stated by them that the values finally adopted depend on the reduction-factor determinations made during the years 1915 to 1921, namely, during cruises IV., V., and VI. (not VI. alone, as Dr. Chree infers).

Certain methods of reduction of the ocean observational data are criticised by Dr. Chree. The fact of the matter, however, is that there is no consensus of opinion as yet on the best methods for the reduction and derivation of so variable an element as the "atmospheric potential gradient." No agreement regarding these matters exists even at observatories in the same country and under the same general administration. He who wishes may readily find fault with the methods of his co-worker. So also as regards the application of "non-cyclic corrections" in the manner advocated by Dr. Chree, there is legitimate cause for difference of opinion. No adequate physical basis for Dr. Chree's assumptions has as yet been advanced.

But even had Dr. Mauchly omitted entirely the series of observations to which Dr. Chree takes exception, his general conclusion as regards the progression of the diurnal variation of the atmospheric potential gradient, according to universal time rather than local time, would not have been affected. Others have arrived at a similar conclusion. Thus, Dr. Hoffmann in 1923 (two years after Dr. Mauchly's first annoumcement in the *Physical Review*, vol. 18, pp. 162 and 477) concluded that the daily extreme values of the potential gradient at Arctic and Antarctic stations, as shown by the available series, occur everywhere at about the same absolute time (*Beiträge zur Physik der freien Atmosphäre*, xi, Heft 1, 1923).

Recent observations in Arctic regions and elsewhere have confirmed in the main the validity of the conclusions by Mauchly and Hoffmann. Thus, Dr. H. U. Sverdrup, in charge of the scientific work of Amundsen's *Maud* Expedition, recently reached the following conclusion from a discussion of all available observations on meteorologically undisturbed days: "Our observations in the Arctic sea, far from land or close to the coast near the 160th meridian of east longitude, give very positive confirmation of the conclusions by Mauchly and Hoffmann."

There are land stations which, evidently because of local influences of one kind or another, show extreme values of the potential gradient at times differing an hour or more from the average times, and there are some land stations which exhibit double maxima and minima in the diurnal variation of the potential gradient. It is generally found at these latter stations that one of the maxima and one of the minima values occur near the average times of extremes of the potential gradient in undisturbed regions. Suffice it to say that all available data at hand at present show that if the hourly values of the atmospheric potential gradient be plotted according to universal time, there will be found a general agreement in phase among the curves for stations in very remote regions, such as is not exhibited if the hourly values be plotted according to local time.

As regards a possible relationship between solar activity and the atmospheric potential gradient, I beg leave to refer the interested reader to my previous articles in NATURE and in the issues of *Terrestrial Magnetism and Atmospheric Electricity*, for March and December 1924, and March 1925. In the last-cited article, p. 17, will be found an extract from the Potsdam observations, published in 1924, showing that Dr. Kähler agreed with me that the Potsdam series, owing to the severe climatic conditions to which that station is subject, is not well suited for investigations as to a possible effect of sunspottedness on the atmospheric potential gradient. But even if the Potsdam series is included in the combined available data at Eskdalemuir (Scotland), Kew (England), and Ebro (Spain), for the complete solar cycle 1913-1922, a positive or direct correlation between atmospheric potential gradient and sunspottedness is found, which amounts to $0{\cdot}54 \pm 0{\cdot}15$, if no account of drift (my *t*-term) arising from one cause or another is taken into account, and to $0{\cdot}78 \pm 0{\cdot}08$, if corrections be made for drift as was done in the volume reviewed by Dr. Chree.

I intend publishing elsewhere some later evidence bearing on this important matter.

It will probably be necessary to await the completion of another cycle and the accumulation of data at widely distributed stations, not subject to local disturbing influence, before all the questions arising as to the precise nature of any solar activity influence on atmospheric electricity may be definitely settled. However, renewed interest has been aroused in the problem, and it is also gratifying in this connexion that, beginning in 1928, the observational work in atmospheric electricity aboard the *Carnegie* will be resumed.

LOUIS A. BAUER.

Department of Terrestrial Magnetism,
Carnegie Institution of Washington,
Washington, D.C., Jan. 31.

If I drew an erroneous inference as to the *Carnegie* reduction factors I regret the fact; but if so, it seems a case not of the reviewer's inadvertence but of the inexactitude of the language quoted in the review. Consultation of pp. 207-209 still leaves uncertainty as to what really happened. On p. 209 it is stated, as Dr. Bauer remarks, that the final mean results were based on "all reduction-factor observations . . . during the years 1915 to 1921," but we should infer from p. 207 that after an observation on April 1915—the original deductions from which we learn from p. 209 were from 24 to 35 per cent. in error—no further observations were taken until the commencement of Cruise VI. (1919 presumably). The other observations chronicled occurred in 1921. I referred to the point in connexion with the question whether the neglect of Potsdam results, which did not support a sunspot influence, was justified on account of an alleged uncertainty in the reduction factor, an uncertainty which seemed to me unlikely to be greater than that affecting the *Carnegie* factors. The rejection of Potsdam data is, however, now advocated on the ground of "the severe climatic conditions to which that station is subject." To this we can only say, what of Eskdalemuir?

How best to deal with the non-cyclic element is, as Dr. Bauer says, a disputed question, but the fact remains that an undesirably large uncertainty owing to unascertainable n.c. changes enters into those observations taken on the *Carnegie* which seemed specially intended for the elucidation of the diurnal variation. At its recent meeting in Zürich the Magnetic Commission of the International Meteorological Committee passed a resolution recommending that, whether n.c. corrections are applied or not, the n.c. change corresponding to any diurnal inequality should be shown explicitly. The news that further observations by the *Carnegie* are contemplated in 1928 is welcome, and it is to be hoped that n.c. uncertainties will be avoided so far as possible.

There is no inherent improbability in a sunspot influence on atmospheric electricity, but there has not been that general agreement between different stations and epochs experienced in the case of terrestrial magnetism, and a reserve of judgment can do us no harm. I think it is also the wise course at present to keep an open mind as to whether the diurnal variation of the potential gradient at sea and in polar regions follows universal time. But as regards ordinary land stations, we can scarcely admit the existence of a prepotent term involving universal time, unless we are prepared to scrap many results accepted at present. At most land stations the diurnal variations near midsummer and midwinter differ considerably in type; at Eskdalemuir and Pavlovsk, where the principal minimum in summer occurs near local noon, the difference is profound.

C. Chree.

Behind the Divining Rod.

I have read, not without surprise, the review in Nature of Feb. 26 under this heading.

I scarcely think it can be truly said that "the use of the divining rod has been looked at askance by men of science." Distinguished geologists have not averted their eyes, and have not neglected to subject its powers, or rather the power of the diviner, to experimental tests, but always with an unfavourable result.

Water is in many places sufficiently widely distributed to afford a fair chance to any one who says "put a hole down here and you will find it," and sometimes there are surface indications which will guide a good observer who may have no knowledge of geology. Occasionally the dowser makes an unexpected hit, but remarkable coincidences are not unknown in other walks of life.

The question has been investigated by the officers of the United States Geological Survey, who found that the successes of the dowser were less numerous than the laws of chance would have led us to expect. Perhaps geologists are to blame for not making the facts more generally known, but their time is usually so fully occupied in serious research that they have none to spare for the exposure of what they have come to regard as a popular delusion. Nor should I be writing now were it not for the serious mischief which is likely to result and has, indeed, already resulted from a recrudescence of this belief in the occult. Too many cases have come under my own observation of misspent labour and money due to misplaced confidence in the powers of the diviner.

The success of dowsers who have acquired reputation are recorded, but of their failures we hear nothing, yet they are often the more remarkable. Employers, who sometimes can ill afford it, suffer in pocket and do not complain; they are unwilling even to give the name of the dowser who has "let them in." I should not myself have any knowledge of these failures were it not that our Geological Department, especially my friend and assistant Mr. C. J. Bayzand, takes a lively interest in water supply and the application of our knowledge of the structure of the country to the finding of water. We are thus brought into contact with dowsers.

Perhaps I may be allowed to give one example of failure of several from out my own experience. One of my friends, having built a house in the country, had to be provided with water, and a dowser was called in to exercise his art. Acting on his advice the well was sunk in the Kimmeridge clay and, as might have been expected, after reaching a depth of nearly fifty feet it gave no sign of water. I was then asked how much deeper it would be necessary to go, and was able to give a definite answer. The distance was close on 68 feet; but I was also able to add that plenty of good water could be got from the Lower Greensand at several places within twenty yards of the ill-chosen spot and at a few feet from the surface. Here the chances were ten to one in favour of the dowser, and his rod gave him the wrong one.

Again, much is heard of the rare cases where a dowser has made a hit after the professional geologist has failed, but instances to the contrary pass without comment. Yet they are not infrequent. Here is a very recent one.

In a district where water could be found at any spot within a mile's distance from a certain village a dowser chose his site for a well; the well was sunk to a depth of 38 feet, but no water was found. The dowser said it was no use to go any deeper, and frankly admitted that he had failed. A geologist was consulted; his advice was to sink a little deeper, and he predicted that water would be found well within an additional 12 feet. The well was deepened and plenty of water was struck at 42 feet. If the dowser could find water at the surface, why not when he was within a few feet of it?

W. J. Sollas.

University College, Oxford,
Feb. 27.

I have every sympathy with Prof. Sollas and with all geologists whose scientific studies have been impudently challenged by ignorant charlatans. But I have met one honest and modest dowser who never exercised his powers for payment and had no theory as to the nature of the faculty which he believed he possessed. From the cases described by

Sir William Barrett, it appears that there are other dowsers who are honest, and it really seems to me that the cause of the dowser's sensations which may lead to the discovery of water is as worthy of study as, say, the polarisation of light that may be used for the microscopic determination of minerals. The investigation may, I think, be better undertaken in either case by specialists who are not concerned with the applications. If there is anything in water-divining, I am sure that it is not occult in the sense of "involving the supernatural, mystical, magical," and if it be occult in the sense of being "beyond the range of ordinary knowledge" (both definitions are given in the Concise Oxford Dictionary) I only urge that efforts should be made to extend that range as it has been extended in recent years to clear up other obscure phenomena. HUGH ROBERT MILL.

The Pressure of Gaseous Mixtures.

A CURIOUS and somewhat unexpected property of the pressure of a gaseous mixture has come to my notice from an examination of some recent experimental work. Holborn and Otto (*Zeit. f. Phys.* 23, 77, 1924; and 33, 1, 1925) have determined the isotherms of a mixture of helium and neon, and of helium and neon alone, and have shown that the isotherms can in each case be represented with great accuracy by a formula of the type

$$pv = A + Bp,$$

when A and B are given suitable values. Since B is small (of the order 10^{-3}), this equation can also be

$$pv/A = 1 + B/v,$$

where v in each case is the ratio of the volume to the volume under standard conditions, and is therefore inversely proportional to the molecular concentration. It follows that B is a measure of the deviation from the perfect gas law. The curious fact emerges that for the same temperature the value of B for a binary mixture may be greater than that of either of the constituent gases. In other words, the pressure of a gaseous mixture may be greater than that of either of its constituents, even when the molecular concentration and temperature are in all cases the same.

I hear, too, from Prof. Masson that Dr. Gibby and he have also discovered the same phenomenon independently in some experiments with mixtures of hydrogen and helium. They are at present extending their work in order to examine this question more closely.

The explanation is to be sought in terms of intermolecular forces. Cohesive forces between molecules tend to lower the pressure, while repulsive forces tend to increase it, and the relation of the one effect to the other depends on the temperature. A mathematical investigation for the particular case when both fields can be represented by inverse power laws (*Proc. Roy. Soc.*, A, 112, 214; 1926) shows that at low temperatures the cohesive forces outbalance the repulsive and the deviation from the perfect gas law (B) is negative. With increasing temperature the effect of the repulsive fields becomes increasingly important until ultimately B becomes positive. Finally, a temperature is reached for which this positive deviation is a maximum, and then the correction falls asymptotically to zero.

This maximum property of the deviation, indicated by theory, is borne out by experiment (Holborn and Otto, *Zeit. f. Phys.*, 23, 86; 1924). The temperature at which the deviation is a maximum is − 140° C. in the case of helium, 150° C. in the case of hydrogen, 260° C. in the case of neon, etc.

In this maximum property lies the explanation of the increased pressure of the gaseous mixture. The temperature of maximum deviation of a mixture lies between those of its two constituents, and near this temperature the deviation of the mixture from the perfect gas law is greater than that of either of its constituents. For a certain range of temperature the pressure of a gaseous mixture may therefore be greater than that of the same concentration of either gas alone.

Furthermore, theory provides an expression for the relative proportions of the gases of a mixture for which the pressure is a maximum at a given temperature. The already-mentioned work of Dr. Gibby and Prof. Masson will, it is hoped, prove to have provided experimental evidence to test this result.

J. E. LENNARD-JONES.

Physics Dept., The University, Bristol.

Members and Correspondants of the Académie des Sciences, Paris.

IN an obituary notice of the late Sir George Greenhill, published in NATURE of Feb. 26, it is stated that he was "a corresponding member of the Paris Academy of Sciences." Sir George was *not* a corresponding *member* of the Academy of Sciences. He was a 'Correspondant' of that Academy 'pour la section de mécanique,' elected in 1921. Similarly, it is stated in the same issue in the obituary notice of the American palæontologist Walcott, that that distinguished American was "a corresponding member" of the Academy of Sciences of Paris. He was not, but was elected by that Académie as 'Correspondant' in the section of mineralogy in 1918. In 1919 he vacated that place on being elected one of the twelve 'membres associés étrangers' of the Academy.

The fact is that the title 'corresponding member' is not employed by the Académie des Sciences—nor by the other Académies which are united as the 'Institut de France.' The individuals constituting one of these Academies are in the first place "Messieurs les Académiciens, membres titulaires de l'Académie." In the Académie des Sciences there are 68 of these 'titular' members, to whom have been added by successive decrees of the State government—10 membres libres, 6 membres non-résidants, 6 membres de la division des applications de la science à l'industrie; and 12 membres associés étrangers. These 102 'membres' of the Academy are classed officially as 'Messieurs les Académiciens,' 'membres de l'Institut.'

Each Academy, excepting the Académie Française, has in addition been empowered to elect *not* 'corresponding members' but *Correspondants*. The Académie des Sciences has 116 'correspondants,' approximately ten to each of the sections into which the Academy is divided. They are *not* 'Académiciens' nor 'Membres de l'Institut.'

There is no restriction as to the nationality nor as to the residence of persons eligible by the Académie des Sciences as "Correspondants." They may be French nationals or foreigners.

The 'membres associés étrangers'—of which there are twelve in the Académie des Sciences—are the nearest equivalent to the 'corresponding members,' the 'foreign members,' and 'foreign correspondants' of some other academies and societies.

Very full information as to the Institut de France and the members and correspondants of its five Académies is to be found in the "Annuaires" published yearly by the Institut and by each Academy. An English account of the history and present organisation of these great bodies would be welcome at this moment, as it would tend to prevent mistakes and confusion in regard to the significance of the titles conferred by them. It is, indeed, most desirable that such an account should be published. Three or four pages of Nature would suffice for a brief and accurate statement. L.

London, Mar. 5.

Solar Radiation and Diathermancy.

The accompanying record (Fig. 1) of the temperatures attained by six thermocouples embedded in a nine-inch brick wall may be of interest. The thermocouples, protected by a thin layer of Chatterton's compound, were embedded at 1/32, 1/16, 1/8, 1/4, 1/2, and 1/1 of the thickness of the wall, which faces west by south.

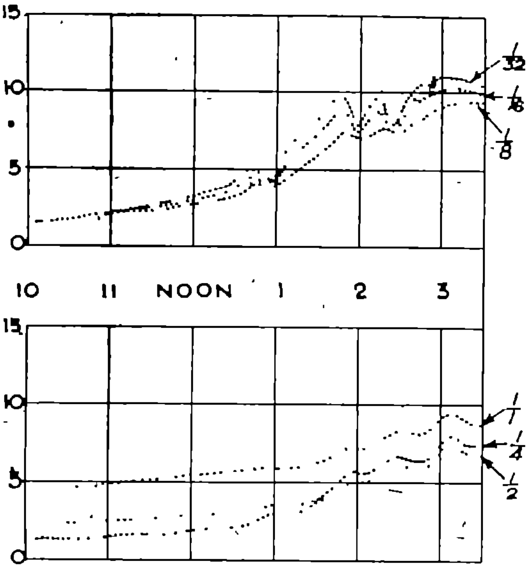

Fig. 1.

A considerable time is required for the transmission of (a wave of) heat by conduction through nine inches of brick, and the rapid response shown in the lower half of the record indicates that an appreciable amount of solar energy is transmitted as radiation.

The troughs at 2 p.m. and 2.25 p.m. in the upper half of the record correspond to the shadows cast by the sides of a wooden ladder. A. F. Dufton.

Building Research Station,
Garston, Herts., Feb. 23.

Sand-flies and Chinese Kala-azar.

Up to the present there have been no records of any infection being produced from Phlebotomus fed on cases of kala-azar, therefore the results of the following experiment may be of interest, since they show that the flagellates which develop in the midgut of sand-flies are capable of producing the infection when they enter a susceptible host. The details of the experiment are as follows:

On Aug. 29, 1926, a female hamster (*Cricetulus griseus*) was inoculated intraperitoneally with a saline suspension of the midgut contents of five infected *Phlebotomus sergenti* var. (exp. S. 75) that had been fed three days previously on a hamster infected with the parasite of Chinese kala-azar. The sand-flies had been kept at a temperature of 30° C., and of those dissected after a three-day interval, six out of eight contained flagellates in the midgut. On Jan. 26, 1927, after an incubation of approximately five months, this hamster died. On examination the spleen was found to be moderately enlarged, and films made from the spleen, liver, and bone marrow, all contained enormous numbers of parasites.

This experiment shows that *Phlebotomus sergenti* var. is capable of harbouring the parasite of kala-azar in a virulent form, and that the parasite is in an infective stage in the midgut three days after being ingested by the insect. The experiment supports the hypothesis that sand-flies are responsible for the transmission of the parasite of this disease.

Amphipneustes.

The Research item headed "Antarctic Echinoidea" (Nature, Feb. 19, p. 294) says: "Antipneustes is a name that replaces Amphipneustes Koehler 1901 to avoid confusion with the unknown Amphipneustea Wiegmann." Since the name Amphipneustea was as unknown to me as to the writer of that note, I have taken some trouble, with the help of Mr. C. D. Sherborn, to get to the bottom of the puzzle. First of all, it appears that the name Antipneustes was proposed, at Prof. Koehler's request, on p. 427 of Lambert and Thiéry, "Essai de nomenclature raisonnée des Échinides," published in 1924, but only just obtained for the Natural History Museum. The supposedly conflicting name Amphipneustea is, on p. 428 of that work, credited to Wiegmann, 1837, without further reference. The "Nomenclator" of Agassiz helps one to track this down to A. F. A. Wiegmann and Ruthe, 1832, "Handbuch der Zoologie," p. 527. The name, however, is applied to a family of Pulmonate Mollusca, and therefore could not conflict with Amphipneustes Koehler, even if the spelling were the same. It may be mentioned that, in 1820, B. Merrem, "Tent. Syst. Amph.," gave the name Amphipneusta to a family of Reptilia.

The upshot of this is that Amphipneustes Koehler 1901 stands, and that Antipneustes is an unwanted synonym; and the moral is: "Verify your references!" F. A. Bather.

Carbon Monoxide Poisoning in the Absence of Hæmoglobin.

May I remind Mr. Haldane (Nature, Mar. 5, p. 352) that it was shown by Faraday, in 1834, that the interaction of hydrogen and oxygen, at a clean, cold platinum surface is prevented by the addition of carbonic oxide. Of course, we never discuss these fundamental things in text-books. Still, his observations are an interesting and useful addition to those of Warburg. I have considered the nature of the influence in my article on catalysis (Nature, Aug. 22, 1925), published in the last Solvay Report. The effect of carbonic oxide upon animals would seem to be that of displacing oxygen from hæmoglobin. I am not aware of any proof that it inhibits oxidation, except by reducing the supply of oxygen. What is surprising is, that carbonic oxide is not generally a more active substance: unfortunately for it, fortunately for us, perhaps (though maybe the reverse holds good), its heat of oxidation is slightly lower than that of hydrogen—hence these tears.

Henry E. Armstrong.

Some Systematic Features in the Distribution of Stars.

By FREDERICK H. SEARES, Mount Wilson Observatory, Pasadena, California.

THE mean distribution of the stars with respect to magnitude and galactic latitude derived by Prof. van Rhijn, Miss Joyner, Miss Richmond and myself,[1] is expressed through values of $\log N_m$ (N_m = number of stars per sq. deg. brighter than m) which for the same latitude, north and south, are the same in all galactic longitudes. The supposition that densities having this characteristic may represent the observed features of stellar distribution assumes the sun to be at the centre of a stellar system having rotational symmetry. Although sufficiently exact for many purposes, this assumption is only a first approximation to the state of affairs in the heavens.

To obtain a further approximation, we may examine the deviations from the mean distribution observed in many parts of the sky. A discussion of the available data by Miss Joyner and myself reveals a conspicuous periodic irregularity extending into high latitudes, which, next to the galactic concentration, is perhaps the most striking feature of the distribution of stars over the sky.

With some additions which need not be detailed here, we have used the same observational material as for the derivation of the mean distribution, namely, the Mount Wilson Catalogue of Selected Areas, the Harvard-Groningen Durchmusterung, and counts from zones of the Astrographic Catalogue published by Turner. The data from the last two sources were reduced to the international photographic scale with the aid of the Mount Wilson Catalogue and the mean distribution table.

Values of the deviation Δ have, in general, been calculated for 10° intervals in longitude and latitude, from 70° N. to 70° S., for each of the limiting magnitudes 9, 11, 13·5, 16, and 18. An important exception occurs only in the case of declinations south of −15°, where, for the faint stars, we have only the data from the Harvard-Gronigen Durchmusterung, with a limiting magnitude of 16·86. Since the systematic change in Δ with magnitude is slow, we have assumed that the deviations found from this catalogue might be taken as representative of those for the limits $m = 16$ and 18 and used with data for these limits from other parts of the sky.

The values of Δ for the same limiting magnitude and the same latitude show in all cases a variation with longitude which can be represented by a simple cosine term. Other irregularities are of course present, notably those corresponding to the obscuration in Taurus and Ophiuchus and to the abrupt changes in density in and near the Milky Way; but underneath all these the large-scale, periodic fluctuation is easily discerned. In spite of some progression, the longitudes of maximum deviation are much the same for all magnitudes and in all latitudes. Further, the amplitude of the variation decreases with increasing distance from the Milky Way; and, finally, the constant term in Δ is always small, which shows that the asymmetry between northern and southern galactic hemispheres is slight.

In a general way these are the characteristics to be expected from an eccentrically located sun, only slightly removed from the galactic plane. Certain systematic differences in the deviations for the two hemispheres suggest, however, the probability of an error in the adopted position of the galactic pole, which is that of Gould. The mean distribution table, although based on data referred to a possibly erroneous pole, is little affected by such an error. The combination of observed densities from all longitudes made in forming this table eliminates the first-order terms in the error; but when observed densities are compared individually with the mean distribution, the error appears in the deviation Δ.

We were thus led to the equation of condition

$$\Delta = s + G + F\cos(\lambda - L) \mp k\cos(\lambda - L_0),$$

in which the upper sign refers to northern latitudes, the lower to southern, s provides for a possible systematic correction to the mean distribution table; k depends on p, the polar distance of the true galactic pole, in longitude L_0, relative to the adopted pole.

The use of this equation only removes the restriction that the sun should be centrally located among the stars, the original assumption of rotational symmetry being tacitly retained. Starting from this modified assumption, we interpret L as the longitude of the centre of the stellar system, and F and G as functions of the latitude, the space-density, and the rectangular co-ordinates of the centre of the system relative to the sun. Although sufficient for present requirements, the equation is correct only to quantities of the first order in p and ρ/R, where ρ is the distance of the sun from the centre and R the radius of the system.

Values of the parameters were calculated for each pair of latitudes, north and south, at 0°, 5°, 10°, 20°, 30° . . . 70°, and where possible, combined into means which are collected in the accompanying table. Only s, which is of no interest here, has been omitted. For L, L_0, and p, the average deviations for results from a single pair of latitudes are 7°·0, 10°·4, and 1°·5, respectively. The internal agreement therefore indicates uncertainties in the tabulated means of the order of 2° to 4° for L and L_0, and of something less than 1° for p; but

m	L.	L_0	p.	$2F$.	$2G$.
9·0	267°	275°	8°·1	0·380	−0·127
11·0	270	296	6·8	0·434	−0·101
13·5	275	319	8·0	0·429	−0·095
16·0	310	357	4·1	0·690	−0·012
18·0	319	350	2·7	0·668	+0·002

---

[1] Cf NATURE, 115, 948, 1925; *Mt. Wilson Contributions*, No. 301; *Astrophysical Journal*, 62, 320, 1925.

residual systematic errors in the data increase these limits considerably; the actual errors in the means are probably of the order of the average deviations quoted.

The significant result is that zones in all latitudes up to 70° show the periodic irregularity of distribution corresponding to the foregoing formula, and give accordant values for the longitude of the centre of the system and the position of the galactic pole. Further, the errors of the respective means are such as to leave the obvious dependence of these quantities upon limiting magnitude open to no serious doubt.

The quantities F and G, as already noted, are functions of the latitude, the space-density, and the distance of the sun from the centre of the system. We should like to utilise their values from all latitudes in a determination of the position of the sun. Substitution of the correct function for space-density and allowance for latitude should reduce all the values of F and G for a given magnitude to constants, from which the co-ordinates of the centre could then be determined. Uncertain knowledge of the density function, together with the inherent complexity of the problem, blocks this direct method of procedure. The use of the simple but incorrect assumption of constant space-density leads to manageable formulæ, but leaves an uncompensated variation in F, and hence yields no very useful result. It does, however, prove again a well-known fact, for the residual variation in F contradicts the assumption of constant density and shows that the stars thin out with increasing distance.

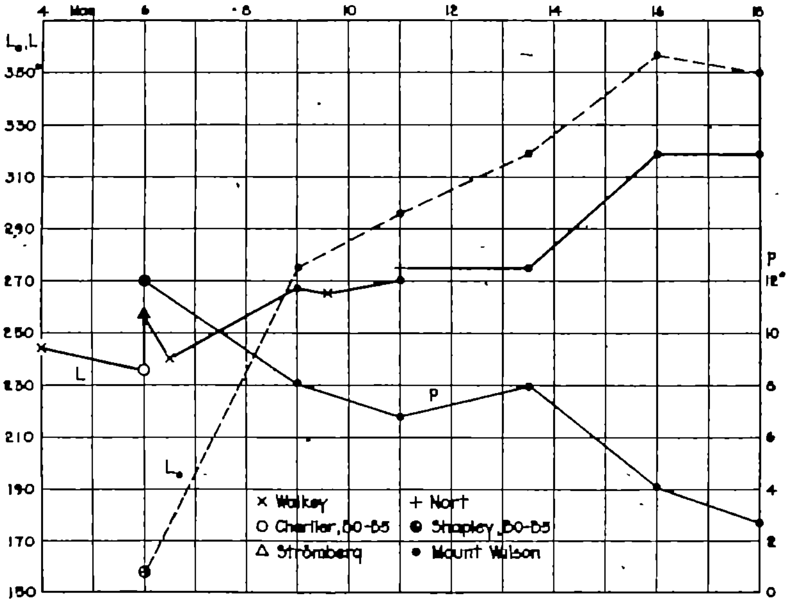

FIG. 1.

Because of the difficulty of utilising all the data, values of F are given only for the galactic region, means for 0° and 5° being tabulated in order to reduce the influence of accidental error. Actually, the double value is given, since that quantity is the logarithm of the ratio of the number of stars in longitude L to the number in longitude $180° + L$. This ratio also depends on the limiting magnitude, increasing from about 2·5 for $m = 9$ to approximately 5 for $m = 18$. An average of 4, combined with the density law of Kapteyn and van Rhijn (which requires revision, and, moreover, is not strictly applicable), leads to a value of 1200 parsecs for the distance of the sun from the centre of the stellar system. This estimate neglects certain obvious refinements, but nevertheless must be of the right order of magnitude. It is so much smaller than Shapley's value of 25,000 parsecs for the distance from the centre of the system of globular clusters, that we may say at once that this system cannot be concentric with the general system of stars now within reach of our telescopes. It is well to remember, however, that the centres of both systems—of clusters and of stars—have practically the same longitude.

The values of G change so little that it seems permissible to tabulate means for all latitudes as an indication of the small displacement of the sun from the galactic plane. A value of $2G$ equal to 0·10 for all limiting magnitudes would correspond to a distance of some 30 parsecs. Actually, however, the asymmetry is appreciable only for stars brighter than the fourteenth magnitude, which show an excess of about 25 per cent. in the southern latitudes. For the lower limiting magnitudes the difference between the two hemispheres is vanishingly small, and we may regard the sun as situated almost exactly in the corresponding galactic plane.

On the whole, we conclude that the systems of stars defined by successive limiting magnitudes differ appreciably in both centring and orientation. In this connexion results by other observers may be recalled. Walkey, Charlier, and Nort found the following longitudes of maximum density:

Limiting *m*.	*L*.
4·0	244°
6·5	240
9·6	265
6±	236 (B0-B5 stars only)
11	275

From dynamical considerations of the characteristics of preferential motion ($m < 6\pm$), Strömberg inferred that the centre of the system might be found in longitude 257°, while Shapley, from a study of globular clusters, adopted 326°. Further, Shapley has shown that the B0-B5 stars brighter than 5·5 lie close to a plane fixed by the pole having the co-ordinates $L_0 = 160°$, $p = 12°$; while the nearer diffuse nebulæ, according to Hubble, define a ‘secondary galaxy’ for which $L_0 = 160°$, $p = 20°$. Other data and certain relevant comments might be added, but for the present account those quoted are sufficient.

The accompanying diagram (Fig. 1) shows the relation of all the results. Those just quoted both confirm and extend the conclusion derived from faint stars. In the systems defined by successive limits of brightness we find a continuous progression in the longitude of the centre and in the position of the galactic pole. The sequence seems to terminate with the galactic clouds; its upper end is the isolated group of helium stars known as the local cluster.

That the B0-B5 stars brighter than 5·5 constitute a local cluster seems clear. Most of these stars are within 500 parsecs and lie close to a plane inclined 12° to the plane of the Milky Way. The fainter B's (7·26-8·25), on the other hand, are more distant, and, as shown by Shapley and Miss Cannon, associated with the fundamental plane of the larger system. Direct evidence also connects some of the A stars with the local cluster. The present data, however, indicate that very faint stars, among them all spectral types, are included in its composition, or at least exhibit some of its characteristics. It is also evident that if the cluster is a separate dynamical unit, it must be much larger than hitherto supposed. Stars of the tenth to the fifteenth magnitude are certainly involved, because those brighter than the tenth magnitude are not numerous enough to influence appreciably the systems the limiting magnitudes of which are 12 or fainter. But these faint stars, which clearly show the progressive change in L, L_0, and p, extend to distances well beyond the most generously placed boundaries of the local system of B stars. It is perhaps questionable if the local cluster in this larger sense can be regarded as a separate unit; the progressive change in the characteristics of stellar distribution is possibly analogous to that shown by Strömberg to be a striking feature of stellar motions.

Fundamental Problems relating to River Pollution.

By H. W. Harvey.

The need for scientific research to provide a basis upon which to deal economically with the pollution of the rivers of Great Britain has been widely recognised during the last few years, and the Government is now prepared to provide adequate financial assistance for this purpose. It is of interest at the present moment to review the lines along which further research of a general character appears at first sight likely to prove most fruitful.

The types of pollution to which rivers and streams in England and Scotland are subject fall into two broad groups. In the first group fall *inorganic* compounds in the effluents from industrial undertakings, having a specific poisonous effect upon aquatic organisms. It may be taken that the chemist and engineer will find effective treatments for almost every such effluent, but their application will depend upon their cost; frequently the limited ground area available makes the simplest type of treatment, involving settling pits or the like, impracticable; frequently a partial treatment only is practicable, or necessary. In the latter case it is essential to know at what dilution the particular toxic substance will have a negligible effect upon various kinds of life natural to the river, for if the ordinary vegetable life in particular is seriously interfered with, slow-running water may be depleted of dissolved oxygen and the natural processes of self-purification cease.

An inquiry into the normal seasonal changes in the aquatic life of an unpolluted stream is already in progress, with the final object of finding the effect of various types of pollution upon them, and of rendering it possible to gauge the extent to which any particular stream is harmfully polluted. It is recognised that considerable quantities of some solutes and matter in suspension may be run into a river without causing any material harm, and a mere change in the nature of the fauna does not provide sufficient ground for recommending the possibly costly treatment of effluents, provided that the capacity of the water to purify itself is not interfered with. This involves a biological research of some magnitude, and certainly of a fundamental nature.

Into the second group fall a wide and varied class of *organic* waste products. If these are turned into a river in suspension they settle upon and stifle the plant life, forming a substratum for fungus growth over the stones, or give rise to putrefaction, which may also happen if organic matter is added in solution. It is the event of putrefaction which opens up problems of the greater interest and the greater complication. As cases in point, the water in which beet is scrubbed at sugar factories, the water in which beans are boiled in American canning factories, and wash water from milk factories containing whey and a little milk, if run direct into a river in any quantity, rapidly deplete its waters of dissolved oxygen and kill off the animal and plant life in the stream, the latter being replaced by a fungus growth attached to the bottom. This is not the case with all organic matter, for I have met with cases where the effluent from treated sewage or even untreated sewage in small quantities appears, if anything, to improve the fishing in swift-running streams.

The question of why quite a limited amount of some organic substances should render a river foul and completely change the animal and vegetable community in it will repay most careful investigation. One general explanation is that putrefaction in the water, by using up the dissolved oxygen, renders it insufficiently aerated. In extreme cases the oxygen content of polluted rivers may fall to zero, as found in the esturine water at Newcastle during periods when little fresh water is coming down the Tyne [1]; in other cases the absorption is not at all complete, yet the biological condition of the river is completely changed for some distance and fish die in the water, although cases have been quoted in which freshwater fish do not suffer from lack of oxygen when the water contains so little as 0·4 c.c. to 1·7 c.c. per litre, less than one-third of the amount necessary for saturation.

Other observers lay stress upon the effect of hydrogen ion concentration: it takes much putrefaction to reduce the pH of a natural water to less than 6, and some freshwater fish have been found flourishing in water of pH 4·4—probably an extreme case. Although changes between pH 6 and pH 8 do undoubtedly affect the nature of the fauna and perhaps of the flora, it seems unlikely that a river would be harmfully affected until the hydrogen ion concentration had risen to around pH 5·5. Wundsch[2] suggests an even lower limit.

The increase in partial pressure of carbon dioxide coincident with putrefaction may have a specific physiological effect additive to that due to a materially increased hydrogen ion concentration. Experiments by Wells[3] in America suggests that this is the case when in conjunction with a low concentration of dissolved oxygen, but these experiments are inconclusive since no account is taken of the hydrogen ion concentration. The influence, if any, of this factor in the deeper water of polluted streams is really unknown.

It appeared self-evident some two years ago, when examining rivers for harmful pollution by organic matter, that lack of oxygen alone, although an excellent indication, was not the only factor giving rise to an abrupt change in stream life, but that this was brought about through the interplay of several factors. Dr. Pruthi[4] very kindly undertook last year to investigate the possible physiological effect of the products of putrefaction upon fish. His painstaking investigation, although admittedly of a preliminary nature, shows that these products play a rôle in limiting fish life in waters where certain kinds of organic putrefaction take place, if not generally. In a 1 in 2000 solution of casein, peptone, or albumen which had undergone putrefaction, small fish quickly died, even after the solution had been thoroughly aerated and its hydrogen ion concentration had been reduced to a normal value for natural water. This is a definite evidence of the production of toxic compounds during the process of putrefaction of these proteins.

The toxic compounds were, in part at least, volatile, for the distillate was observed to be highly poisonous to the test fish. An observation suggested that such compounds are readily oxidised, for heating a putrefied casein solution to 70° for twelve hours rendered it innocuous, whereas before heating it killed test fish in one hour. These experiments bring out the significance possessed by the toxic compounds which appear as by-products of protein putrefaction, a factor hitherto almost ignored. It will be a fruitful problem to investigate the nature and production of these compounds from various organic substances likely to be thrown into rivers, their effect upon the fauna generally, and the possibility of accelerating their oxidation.

Until knowledge has been obtained of how each factor affects not only fish but also other forms of aquatic life, particularly diatoms, attempts to deal with effluents containing dissolved organic matter must remain empirical. As soon as a sound basis of theoretical knowledge is available, the risk of expensive installations proving unsatisfactory will be greatly minimised, and firm ground will be provided for efficient legislation causing the least possible expense to the various interests involved.

In attacking problems of this nature, provided the investigations proceed without undue haste and there is some freedom allowed to follow up cognate issues which present themselves during the course of every research, it is impossible to foresee where new knowledge may in time lead. We cast away many tons of combined nitrogen and phosphorus and of fats into our rivers every year. Our inland waters are capable of yielding many more tons of edible fish annually, and it is very possible that this will become an economic possibility in the not far-distant future.

Comets and the Law of Gravitation.

By Dr. A. C. D. CROMMELIN.

One of the most interesting results of the discovery of the law of universal gravitation was the light that it threw on the nature of cometary movements, which had previously baffled astronomers. In classical times comets seem to have been generally recognised as heavenly bodies: this is illustrated by the remarkable prediction of Seneca: "Some day there will arise a man who will demonstrate in what regions of the heavens the Comets take their way; why they journey so far from the other planets; what their size, their nature." This prediction received a striking fulfilment some 1600 years later, when Newton's brilliant discovery of the law of gravitation, which permits motion in any of the conic sections about a centre of attraction, made it at last possible to determine the orbits of comets.

After the time of Seneca, science in Europe underwent a remarkable retrogradation as regards the nature of comets. They came to be regarded as mere atmospheric exhalations, a supposition that their great size and rapid motion rendered plausible, but capable of easy refutation from the fact that they rise and set like the stars. The erroneous conception had two unfortunate effects: first, it led to comets being regarded as the bearers of plague, famine, and war; secondly, it caused very little attention to be paid to their positions among the stars, so that in several cases this is far more precisely stated in Chinese and Japanese records than in European.

Tycho Brahe made it clear, by the absence of appreciable parallax, that comets were at least several times more remote than the moon, and so restored them to the status of heavenly bodies. When Kepler, from a study of Tycho's observations, demonstrated the elliptical character of the planetary orbits, the idea occurred independently to Hevelius, Borelli, Lower, and Dörfel that comets might also have elliptical paths of a much more elongated character than those of the planets, so that they remained invisible for the greater part of their period of revolution. These ideas remained merely conjectural until Newton had demonstrated that the law of universal gravitation, varying inversely as the square of the distance, gave a full explanation of the lunar and planetary movements, and indicated the possibility of motion in conic sections of any eccentricity.

Thus at last it became possible to calculate the orbits of comets. Many difficulties arose in the practical work, owing to the roughness of the observations and the small arc covered by them. It has needed long experience and the continued work of a long series of mathematicians to reduce the calculation to its simplest form. At first it offered great difficulties even to Newton. He was unfortunate in choosing as one of his examples the great comet of 1680–81, which had the very small perihelion distance 0·006. It will be remembered that the 'daylight' comet of January 1910, which also had a small perihelion distance, baffled the orbit computers in the early days of its apparition. So Newton is stated to have lost two months in 1685 in attempting to deduce the orbit of the 1680 comet, though he ultimately succeeded in obtaining a tolerable result, and in proving that the morning comet of November 1680 was the same body that was seen in the evening in the following January.

Newton has freely acknowledged in the "Principia" the great debt that he owed to Halley for carrying the cometary computations much further than he himself had the leisure or inclination to do. As is well known, Halley took up the application of the law of gravitation to comets with the greatest enthusiasm, and calculated the orbits of 24 of them from observations extending over two centuries, which he had collected with much diligence. He was rewarded for this great labour by the discovery of the periodic comet that bears his name, which he found to have appeared in 1456, 1531, 1607, 1682. He thus reduced these wandering bodies to recognised members of the solar system, his work being afterwards vindicated by the return of his comet in 1759, in almost exact accordance with his prediction. Thus it may be said that Newton's discovery, vastly useful as it was for the prediction of lunar and planetary motions, produced a still more revolutionary advance in the world of comets.

Dwelling-places, Portraits, and Medallic Illustrations of Newton.

THE particulars concerning the birth and upbringing of Newton, as well as his domiciliary situation and circumstances while at Cambridge, are so well known that they need no further narration. But his eventful and full life in London, in east and west, covering a period of thirty years, and when in the zenith of fame, may perhaps receive some attention. It suffices, as a preliminary, to recall that, in 1701, Newton resigned the Lucasian chair at Cambridge. He had earlier (1696) been appointed Warden of the Mint, and later (1699) Master.

DWELLING-PLACES.

Towards the close of 1697, Newton went into residence in Jermyn Street, where he stayed until 1710. From here he wrote to Flamsteed, under date 1698, whilst Bentley addressed a letter to him, so late as 1709, in this wise: "Sir Isaac Newton, at his house in Jermin Street, near St. James's Church, London." After a short stay in Chelsea, "near the College," Sir Isaac removed about the end of September 1710 to a large and commodious house in St. Martin's Street, Leicester Fields, occupying this as tenant during the rest of his life. Actually, however, he ceased to live in it from 1725, for, owing to indifferent health, he had gone into quarters at Kensington, dying there in 1727. It was in that year that his name was erased from the books of his former parish. The identification of the house in Kensington where Newton lived was established and recorded in 1852 by Mr. Joseph Jopling, an architect, who thereupon received the thanks of the president and council of the Royal Society. It was probably in early days within sight of Kensington Palace.

Newton had procured (with the active assistance of Wren), in the very year of the acquisition of a new domicile for himself, a home for the Royal Society in Crane Court, Fleet Street. Possibly, in determining this abode, he was mindful of the claims imposed upon his time by the weekly meetings of the Society. He would not have far to go from Leicester Fields to Crane Court.

In St. Martin's Street Newton lived in excellent style, kept a carriage, and maintained an establishment of three male and three female servants. Ample hospitality was proffered without ostentation or vanity, his niece, the accomplished Catherine Barton, presiding at the philosopher's table. She married John Conduit in 1717, who, in later years, wrote "nobody ever lived with him but my wife, who was with him near twenty years." Eminent foreigners visiting London were always sure of a warm welcome. Newton built a small observatory on the roof of his house. At the moment of writing, the foundations of a spacious new building are in progress on the site of the derelict residence of Newton. It may be hoped that a suitable commemorative tablet (more appropriate at least than that in Jermyn Street) will be affixed in due time.

Several engravings of the St. Martin's Street house are extant. There is one in the *European Magazine* for 1811. In Smith's "Historical and Literary Curiosities" is an engraving (published 1836) showing the interior of the observatory; and another of the house itself (published 1837). Long after Newton's death, a story got into circulation that the house was at one time taken by a foreigner, who built an observatory at the top, storing there some obsolete apparatus. He advertised the place as being on view in the state left by Newton, and many visitors were imposed upon. The circumstance is alluded to by J. T. Smith in "An Antiquarian Ramble in the Streets of London" (1846), and by the Rev. W. G. Humphry, sometime Vicar of St. Martin-in-the-Fields, in a pamphlet issued in 1857.

Portraits.

The lineaments of Newton have been conveyed to canvas, and thence to posterity, by many celebrated painters—notably by Kneller, Vanderbank, Thornhill, Charles Jervas, and Seeman. Many engravings from these personal studies have been produced by masters in their art; in addition, there are innumerable woodcuts. In the subjoined notice, while space permits only brief reference to selected examples of portraiture, some idea of the manner and time of presentment may, however, be gathered.

The earliest authenticated portrait of Newton is that by Sir Godfrey Kneller (deceased 1723) in the possession of the Earl and Countess of Portsmouth, at Hurstbourne Park. It represents him with long natural hair and shirt open at the neck. Painted in 1689, it shows Newton at the age of thirty-eight. A faithful engraving of this portrait was made by T. O. Barlow, R.A.

There is also a fine study of Newton by Kneller, painted in 1720, at Petworth House, Sussex, in the ownership of Lord Leconfield. The philosopher is represented nearly whole length, seated in an elbow chair, in wig, looking to right, the right arm resting on an abutment; in left hand, a glove. The picture was engraved in stipple by W. T. Fry for Edmund Lodge's "Portraits of Illustrious Persons" (folio 1831).

The three-quarter canvas by John Vanderbank in the National Portrait Gallery, St. Martin's Place, is of high interest. Newton, with flowing hair and white neckerchief, is represented seated in a high-backed chair, one arm resting. An open book on a table is before him, a leaf of which he holds. In the background is a globe. The legend appended describes him as "The Great Philosopher; Discoverer of the laws of gravitation, and of the nature of light and colour. Author of the *Principia*." The pose of the head, drawing of the hands, and fine colouring of the face, arrest attention. The whole composition is in harmonious balance. We know that Vanderbank's pencil received the stimulus of a long and faithful attachment to Newton.

At the Royal Society, holding place of honour in the meeting-room, over the president's chair, is John Vanderbank's impressive portrait of Sir Isaac, painted in 1726, when Newton was eighty-four years old. It is nearly whole-length, and the subject is seated in an armchair, in velvet gown, with long white neckerchief and white ruffles at the wrists. A mezzotint from the portrait was engraved by J. Faber, jun. The picture was presented to the Royal Society in 1841 by Mr. C. B. Vignoles, F.R.S.

Mention must not be omitted here of Vanderbank's portrait of Newton, painted in the year previous to the foregoing. The original is at Trinity College, Cambridge. An engraving from it forms the frontispiece to the "Principia," third ed., 1726.

The Royal Society possesses also a portrait by Charles Jervas, given in 1717 by Newton himself. No particulars of this gift, by letter, exist. Doubtless it hung in Crane Court. The painter was sometime a pupil of Kneller.

Martin Folkes, often Sir Isaac's deputy in the chair in his declining health, gave the Society a portrait which is signed by Vanderbank.

One of the most interesting Newtonian portraits is that by Enoch Seeman, painted for Thomas Hollis, F.R.S. It is recorded in Hollis's "Memoirs" (2 vols. 1780, privately printed, many plates) that on Oct. 29, 1761, he presented to Trinity College, Cambridge, an original portrait of Sir Isaac Newton "painted in the year 1726." Comment is made that "Mr. Hollis's expenses this year [1762] to artists in the painting and engraving way appear to have been very considerable, particularly to Signor Cipriani; and likewise to Mr. MacArdell for a mezzotint of Sir Isaac Newton from the portrait presented to Trinity College." This engraving, it should be said, was published in Vol. 2 of the "Memoirs," and bears a quotation from Voltaire. Its rarity has led to the acquisition of the "Memoirs" for the purpose of abstraction of the engraving. Instances are within the writer's knowledge. A copy of the "Memoirs" exists in the library of the Society of Antiquaries, but we look in vain for the mezzotint. On the other hand, a copy in the Royal Institution is perfect in all respects. James MacArdell was a brilliant craftsman who executed plates of many persons of distinction. He died in London in 1765.

In the drawing-room of the Master's Lodge, Trinity College, Cambridge, is a half-length portrait of Newton, in gown, executed in 1710 by that eminent artist James Thornhill (knighted 1720), who was court sergeant-painter in Newton's London days. It was bequeathed to the College by Dr. Richard Bentley. Writing to Newton in 1709, Bentley says: "I hope my picture at Thornhill's will have your last sitting before you leave the town." It was engraved as an oval by J. Simon.

The Countess of Portsmouth kindly supplies the information that at Hurstbourne Park, in addition to the Kneller of 1689, and one of 1702, as well as a head by Thornhill, the family possess a small sketch, believed to be by Kneller, a bust by

Roubiliac, and a death mask of Newton, the last named presented by Mr. Alfred Gilbert, R.A.

Medallic Illustrations.

Numerous medals and tokens were in circulation at home and abroad after Newton's death. Most of them bear the bust of Newton; on a reverse of one is a representation of Newton's monument in Westminster Abbey. A medal (it is rare), designed by James Roettier in 1739, shows the bust of Newton, and for reverse, science, personified as a female, with wings, is seated on a rock, holding a diagram of the solar system. The Royal Astronomical Society's gold medal bears Newton's head. This yearly gift replaces an earlier type by George Mills, awarded for the first time in 1822, but superseded in 1831. On the reverse was an inscription taken from verses by Halley prefixed to the first edition of the "Principia." The Royal Society's annual Royal Medal perpetuates Newton through a reproduction on the reverse of Roubiliac's statue in the ante-Chapel of Trinity College, Cambridge. McGill University, Montreal, awards a medal which carries a head of Newton. The list admits of extension.

T. E. James.

News and Views.

The Grantham commemoration of Newton on Mar. 18–20 was a brilliant success and reflected much credit on the Yorkshire Branch of the Mathematical Association and its able and active president, Prof. S. Brodetsky. It would be difficult to say which was the best-arranged part of the programme—the scientific meeting, the visit to the Manor House at Woolsthorpe, the dinner, or the service in Grantham Church. All went off without the smallest hitch. But there can be no doubt as to the most impressive part. The gathering in the magnificent church, crowded in every corner, the bright robes and the band of scholars, the hearty singing of the finest old psalms and hymns, the exquisite choice of passages for reading, above all, the superb sermon of the Bishop of Birmingham, made a profound impression. The end fitly crowned the work of commemoration, and those who came from a distance—some 150 of them—dispersed in the afternoon full of gratitude to Prof. Brodetsky, Mr. A. B. Oldfield, and other devoted members of the Mathematical Association, as well as to Mr. Christopher Turnor, Sir Charles Welby, the Mayor of Grantham, and others who generously provided hospitality for some of the visitors.

Celebrations are now of almost monthly occurrence, and some people may think there are too many of them. Happily in the case of the Newton commemoration there was no doubt from beginning to end, and the concurrence of the many sides of his marvellous character was well brought out. Even the weaker points of his humanity found their recording angels in the comparative privacy of the after-dinner speeches. His interest in the 'stinting' of the farmer on his Manor of Woolsthorpe and in the actual working of the estate, his action at the Mint which restored the guinea to its face-value, and his own operations in the share market, these were probably the sides of his work which were new to the largest number of the audience. To these should be added Dr. Barnes's discovery of the state of his theological beliefs and the probable reason why he abstained from taking orders. Altogether, the occasion was worthy of its subject, and stands out as a very moving and instructive commemoration. For the purposes of education such a function has a double aspect, and it is impossible to say which is more valuable. On one hand, it introduces a large public to the work of men whose thought in its entirety is inaccessible to most, but who have a human and a beneficent quality which all can appreciate. On the other hand, it turns the thoughts of men of science to the human and historical aspects of their subject. If we think of the great founders, we are bound to fit them into their place in the evolution of thought, to regard them, not only as real human beings like ourselves, but also as steps in the upward march of the human spirit.

Several telegrams and other messages were read at the scientific meeting and the dinner. Prof. Einstein sent a letter to Dr. Jeans, secretary of the Royal Society, but it was unfortunately not handed to Dr. Jeans in time to be read. We are glad, however, to be able to publish a translation of the letter. "More than any other people," wrote Prof. Einstein, "you Englishmen have carefully cultivated the bond of tradition and preserved the living and conscious continuity of successive generations. You have in this way endowed with vitality and reality the distinctive soul of your people and the soaring soul of humanity. You have now assembled in Grantham in order to stretch out a hand to transcendent genius across the chasm of time, and to breathe the air of the precincts where he conceived the fundamental notions of mechanics and of physical causality. All who share humbly in pondering over the secret of physical events are with you in spirit, and join in the admiration and love that bind us to Newton. What has happened since Newton in theoretical physics is the organic development of his ideas. Force became independent reality to Faraday, Maxwell, and Lorentz, and then went over into the conception of the field. The partial differential equation has taken the place of the ordinary differential equation used by Newton to express causality. Newton's absolute and fixed space has been converted by the theory of relativity into a physically vital frame. It is only in the quantum theory that Newton's differential method becomes inadequate, and indeed strict causality fails us. But the last word has not yet been said. May the spirit of Newton's method give us the power to restore unison between physical reality and the profoundest characteristic of Newton's teaching—strict causality."

THE Great Barrier Reef Committee of Australia, at present under the chairmanship of Prof. H. C. Richards of the University of Queensland, has for some years past promoted researches on the geology and biology of the Great Barrier Reef. It has now extended an invitation to Mr. F. A. Potts, of Trinity Hall, Cambridge, lecturer in zoology in the University, to carry out a programme of marine biological research under its auspices, and has announced its intention of placing at his disposal a sum not exceeding £1000 for the expenses of the expedition. This action on the part of Australian men of science offers a unique opportunity for a British investigation of some of the basal problems of tropical marine biology. It is proposed that, in addition to the leader, the party shall include experienced workers, one of whom would work on the direct connexion of the physico-chemical conditions and the phytoplankton, while a third would investigate the feeding mechanisms of the sedentary organisms which constitute the fauna of a coral reef. In the first case at least it is hoped that the observations will extend over an entire year. To carry out these proposals it is necessary to raise a substantial sum of money in addition to the original guarantee—at least another £1500 is required. To assist in the scientific organisation of the expedition an influential committee has been formed consisting of Sir Matthew Nathan, Ex-Governor of Queensland (chairman), Sir Joseph Cook, Sir Sidney Harmer, Sir Gerald Lenox Conyngham, Rear-Admiral Douglas, Prof. Stanley Gardiner, Dr. E. J. Allen, Dr. G. P. Bidder, and Mr. A. R. Hinks. It is very much to be desired that the investigation of such general problems, never before attempted in tropical seas, should be initiated by British men of science and the study of marine biology in its broader aspects fostered in Australia, which possesses such boundless marine wealth. The party will start in July and work in the neighbourhood of Cairns, Queensland.

THE recent announcement of the purchase of a large part of the Ashridge Estate by the Zoological Society of London will be welcomed by all scientific workers and lovers of Nature, for it is intended to establish there not only a large Zoological Park but also sanctuaries for British mammals, birds, insects, and the rarer chalk-loving plants. The site chosen is very happily situated on a sunny slope of the Chilterns about three miles south of Dunstable and near the picturesque village of Whipsnade. The total area comprises a little more than 400 acres, and includes every type of ground suitable for the objects which the Society has in view. The highest part of the property, which is well wooded, is more than 700 feet above sea-level, and at this point there is a large, well-drained plateau which is to be set aside for herds of deer, antelope, and other ungulates. On the west there is a steep descent into the valley, and it is here that terraces will be made for the larger carnivores, with deep ditches to separate them from each other and the visiting public. The development of the new Zoo will necessarily be slow, and for the present it will be used solely as a sanatorium for any animals which need a rest and change of air from the gardens at Regent's Park.

THERE is much work to be done before a start can be made on any scheme of development of the Zoological Society's newly acquired property. An artesian well will have to be sunk to ensure a good supply of water, and electric power will be needed for pumping, heating, and lighting. Dwelling-houses for the staff and administrative offices must be erected, while the whole area under consideration must be enclosed by a ring fence. At present, friendly negotiations are proceeding with the local authorities concerning certain rights which they hold over a portion of the land. The results of these negotiations will probably be incorporated in a private Act of Parliament, and until an agreement is reached on all the points under discussion, nothing definite in the way of development will be put in hand.

PROF. A. S. EDDINGTON'S tenth and last Gifford Lecture in the University of Edinburgh on Friday, Mar. 18, was on science and mysticism. Granted, he said in the concluding part of the lecture, that physical science has delimited its scope so as to leave a background which we are invited to fill with a reality of spiritual import, we have yet to face a difficult criticism. "Here," says science, "I have left you a domain in which I shall not interfere. I grant that you have some kind of approach to it through the self-knowledge of consciousness, so that it is not necessarily a domain of pure agnosticism. But have you any orderly system of inquiry into this domain comparable to the system of science? Have I any reason to regard the current religious interpretation of it as more than muddle-headed romancing?" Prof. Eddington declared himself unable satisfactorily to answer this question. In science, he said, we often have convictions as to the right solution which we have never been able to justify, and even that strict logician, the pure mathematician, reluctantly allows himself some prejudgments. Why is it that we attach so much truth and importance to the values determined by the mind, unless they are reflexions of mind of an Absolute Valuer? How can that mystic unity with the world, experienced in exceptional moments, continue to feed the soul in the sordid routine of life, unless we can approach the World-Spirit in the midst of our cares and duties in that relationship of spirit to spirit symbolised in the name of the Father?

AN appropriate, pleasing, and sympathetic ceremony was held on Mar. 15 at the Albert Dock Hospital, London, when the Minister of Health, the Right Hon. Mr. Neville Chamberlain, unveiled a memorial plaque to the late Sir Patrick Manson, the 'father' of tropical medicine, in the very ward in which he, with the efficient aid of the Seamen's Hospital Society, established the clinical teaching of tropical medicine some twenty-eight years ago. Sir Arthur Clarke, the chairman of the Seamen's Hospital Society, in introducing the Minister of Health, referred to the close association of Manson, the Chamberlain family, and his Society, in the firm belief that this family association might continue. Mr. Chamberlain, whose speech was permeated with great breadth of vision, emphasised the bearing of the main discoveries of tropical medicine on the trend of medical science as a whole, and in doing so showed remarkable familiarity, not only with the technical side, but also with the personal attributes of the subject of his discourse. His comparison of the historic association of Manson and Ross with that of Darwin and Wallace received general approbation as a singularly apt allusion. His familiarity with this department of medicine and his evident keenness and enthusiasm form a sure indication that the Minister of Health is alive to the paramount importance of tropical medicine in the Empire's affairs. Dr. G. C. Low, the senior physician, in proposing a vote of thanks to the Minister of Health, laid special emphasis on the persistence of Manson, ably backed by Mr. Joseph Chamberlain, in face of official and professional opposition to his schemes. Prof. R. T. Leiper, in seconding this vote, paid a special tribute to the personality of Sir Patrick Manson as portrayed in the recently published account of his life and to his genius in stimulating and encouraging research.

Water-finding apparatus has been on the market for many years, but our attention has only recently been directed to official tests carried out in India by the Department of Agriculture, Bombay, and described in the department's Bulletin No. 72 of 1915, revised in 1925. In this Dr. H. H. Mann and Mr. D. L. Sahasrabuddhe detail work done with two forms of water-finder manufactured in England, the mechanism of which is either secret or not very clearly described, but both act by the horizontal deflexion of a magnetic needle set in the magnetic meridian when placed directly above a flowing stream of underground water. Certain coils of wire are arranged in a chamber below the balanced needle, and these have no external connexions or batteries attached. The theory appears to be that a current is induced in the coils by earth-currents following the path of least resistance through water channels. The indications are of variable strength and show some indefinite diurnal range; when over a stream the magnet has been found to swing through as many as 20° to east or west with a slow irregular motion, taking perhaps half an hour to complete an oscillation. The observations were carried out in the Trap rocks of the Deccan, where the whole water-supply is from wells, and 40 per cent. of the wells sunk by native cultivators are said to be failures. All the cases cited of wells sunk in places found by the apparatus appear to have been successful. The results seem to satisfy the Bombay Department of Agriculture, and reference is made to equally satisfactory results obtained by Mr. S. B. Hudlikar, the Indore State geologist, and by Mr. G. B. Brooks in Queensland. The detection and measurement of earth currents would appear to be a useful field of research, and much might be expected from the use of electrical refinements made available since the inventions referred to in this paragraph. It is not impossible that investigations in this direction would throw light on the physical basis of dowsing.

Mr. Emil Hatschek discussed rigidity and other anomalies in colloidal solutions in his Friday evening discourse delivered at the Royal Institution on Mar. 18. The study of the viscosity of colloidal solutions by means of the capillary instrument was begun by Thomas Graham. Investigations by later observers using the same method revealed anomalies. Definitive attempts to elucidate the problem, made by Prof. W. R. Hess and by Mr. Hatschek independently, established the fact that the viscosity of colloidal solutions, unlike that of normal liquids, is not independent of the velocity gradient, but varies with it. The variation is the same in all solutions so far studied: the viscosity decreases with increasing gradient and approaches or reaches a constant value, while with decreasing gradient it grows asymptotically. A possible and widely accepted explanation of the anomalous viscosity is that colloidal solutions possess rigidity. It can be demonstrated mathematically that a liquid possessing rigidity would have a variable viscosity. Rigidity in many of the colloidal solutions can be demonstrated, and the modulus can be measured by very delicate apparatus. In most cases it increases with age; in all solutions examined rigidity disappears on warming to about 40°, but returns in varying degrees on cooling. Since rigid solutions, unlike normal liquids, can be deformed, they show double refraction when sheared. Suggestions put forward to account for these anomalies amount in general to assumptions of special structures in these liquids, of an order of magnitude larger than molecular, but modelled on the shape of the molecule. Such explanations are, however, inadequate on account of the extreme chemical diversity of the substances which exhibit anomaly. Furthermore, variable viscosity is a property also of coarse suspensions of nearly spherical particles in indifferent normal liquids, which do not arrange themselves into any ordered structures. The peculiar properties of colloidal solutions make them transitional systems possessing properties of both the liquid and solid state.

Mr. Ormsby-Gore, in his lecture on Mar. 7 on Nigeria before the Royal Geographical Society, laid stress on the success which has followed the British policy in Northern Nigeria of governing so far as possible through the emirates and the native administrations. The greatest disruptive power in West Africa had proved to be the introduction of English law and English judicial procedure. In the northern provinces, justice has been administered in the native courts, and the ancient system of taxation has been continued, 50 per cent. of the tax, soon to be increased to something like 70 per cent., being returned to the native treasury. In Southern Nigeria, however, owing to the absence of any organised chieftainship and the more primitive character of the social organisation, British rule has been more direct, and it has been necessary to build up native courts and native treasuries. Mr. Ormsby-Gore showed well-founded anxiety in speaking of the possible disruptive effects of the projected rapid development of the railway system. An administration which is both well aware of the dangers of detribalisation and sympathetically and intelligently concerned in the maintenance of native institutions as a means of discipline should be well able to cope with the situation. Nigeria should have less cause to fear than other parts of Africa.

The British Non-Ferrous Metals Research Association has arranged an exhibit at the Science Museum, South Kensington, which is designed to show the assistance given to British metal industries by the research and auxiliary services of an industrial research organisation. The Association carries on a twofold service: first, in the prosecution of research work either of a fundamental and scientific character or of direct practical utility; and secondly, in maintaining a highly organised information service which operates for the general benefit of the Association as a whole and to meet the specific needs of individual member firms. The present exhibit is concerned chiefly with eight of the Association's researches, chosen as typical from among eighteen major investigations at present in progress, and gives some idea of the scope of each piece of work and the progress which has so far been made. Investigations on the following subjects are illustrated: Effect of impurities up to 1 per cent. on the properties of copper; gases in copper castings; brass casting (the surface and internal soundness of ingots); the jointing of metals; die-casting alloys (brass and bronze alloys and aluminium alloys); 'wiped' plumbers' joints; spectroscopic assay of zinc; and atmospheric corrosion. Information is also displayed illustrating the Association's administrative, library, and information services, with some examples of the work normally carried out in these departments.

At a meeting of the Royal Society of Edinburgh held on Mar. 14, the following were elected fellows: Dr. D. A. Allan, Newcastle-upon-Tyne; Mr. J. Barnett, Edinburgh; Mr. S. E. Bastow, Edinburgh; Mr. D. L. Bryce, Horley; Prof. H. G. Cannon, Sheffield; Dr. T. M. Finlay, Edinburgh; Dr. A. W. Greenwood, Edinburgh; Dr. J. M. Gulland, Oxford; Dr. H. S. Holden, Nottingham; Mr. O. D. Hunt, Glasgow; Dr. J. Hyslop, Glasgow; John Alexander Inglis of Auchindinny and Redhall; Prof. E. T. Jones, Glasgow; Dr. W. P. Kennedy, Edinburgh; Prof. J. M. M. Kerr, Glasgow; Dr. C. G. Lambie, Edinburgh; Dr. D. M'Intyre, Glasgow; Dr. Mohamed Reda Madwar, Helwan; Dr. F. N. K. Menzies, London; Prof. T. P. Noble, Bankok; Mr. W. J. Owen, Melbourne; Mr. C. Patterson, Edinburgh; Dr. H. H. Read, Edinburgh; Mr. J. E. Richey, Edinburgh; Dr. I. Sandeman, Edinburgh; Dr. R. Schlapp, Edinburgh; Prof. F. W. Sharpley, Dhanbad, India; Prof. E. Shearer, Edinburgh; Dr. C. W. Wardlaw, Glasgow; Mr. C. B. Boog Watson, Edinburgh; Dr. W. T. H. Williamson, Edinburgh.

The French Association des Anatomistes has arranged to hold its meeting in London on April 11-13 in co-operation with the Anatomical Society of Great Britain and Ireland. The congress will meet at University College. About 150 members of the two societies are expected, and as the French society includes members coming from several of the European countries, namely, Belgium, Italy, France, Holland, Switzerland, Spain, Portugal, Poland, and Czechoslovakia, the congress promises to be an international one such as hitherto has not been held in Great Britain. On the evening of April 11 a conversazione will be held at University College. One of the most interesting features of the meeting will be the reception by Mr. Henry S. Wellcome in his Historical Medical Museum on Tuesday, April 12, at 8 P.M. On the following evening a dinner will be held at King's College. Arrangements have been made for the members of the congress to visit Cambridge as the guests of Prof. Wilson. There will be a trade exhibit dealing with scientific appliances and other technical equipment for anatomical study.

In the *Metropolitan-Vickers Gazette* for February, details are given of the important power station of the Bristol Corporation which will be constructed at Portishead on the Bristol Channel about seven miles from Bristol. As it has received the approval of the Electricity Commissioners, it is doubtless the forerunner of many similar large power stations. The ultimate capacity of the station is 280,000 kilowatts, and provision will be made to transmit the whole output at a pressure of 33,000 volts to the corporation power station in Bristol. The first section of the station will be equipped with two turbines of 20,000 kilowatts capacity, each driving a three-phase 50-cycle alternator generating at 11,000 volts. The generating plant operates at the high speed of 3000 revolutions per minute and the boiler pressure will be 325 lb. per square inch. These increasing speeds and pressures show the trend of modern practice. Another point of interest is the method of obtaining cooling water for the condensers. Circulating water will be taken from the Bristol Channel, and 35,000 gallons of water per minute will be required for the first two sets. Since the tidal fluctuation is exceptional, involving a variation of about 50 feet in water level, it has been decided to place the condensers at such a level that the full syphon action will be obtained at all states of the tide. This effects a large saving in the power required for operating the cooling water system.

Arrangements are being made for a repetition at Easter of the tour in the Dordogne organised by Prof. Patrick Geddes for the purpose of visiting the rock paintings and carvings of the palæolithic caves of the area and for regional survey work. The tour will last from April 15 until 30. The first week will be spent at Les Eyzies and will be devoted to archæological study under M. Peyrony. For the remainder of the time M. Paul Réclus will conduct regional survey work in a series of expeditions in the country around Domme. Particulars as to route, cost, etc., may be obtained from Miss Moya Jowitt, 33 Gordon Square, London, W.C.1.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned :—A chief veterinary inspector under the Surrey County Council—The Clerk of the County Council, County Hall, Kingston-upon-Thames (Mar. 31). A senior demonstrator of pathology in St. Bartholomew's Medical College—The Dean, St. Bartholomew's Medical College, St. Bartholomew's Hospital, E.C.1 (April 6). An officer-in-charge of the wood preservation section of the Forest Research Institute, Dehra Dun, India—The Secretary to the High Commissioner for India, 42 Grosvenor Gardens, S.W.1 (April 8). A head of the textile department of the Municipal Technical College, Bolton—The Director of Education, Nelson Square, Bolton (April 8). An assistant in the Forest Products Research Laboratory, for work on the identification and structure of wood, and an assistant in the Entomology sub-section of the same laboratory—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1 (April 9). An assistant government chemist for forest research in the Federated Malay States—The Private Secretary (Appointments), Colonial Office, 38 Old Queen Street, S.W.1 (April 14). An assistant to the pathologist of the Manchester Committee on Cancer, for laboratory work and the supervision of the maintenance of animals—The Chairman of the Manchester Committee on Cancer, 1 Mount Street, Manchester (April 16). Demonstrators (men or women) in the departments of chemistry and physics of Bedford College for Women—The Secretary, Bedford College for Women, Regent's Park, N.W.1 (May 7). A professor of natural history at University College, Galway—The Secretary (May 14). A professor of mathematics and a reader in physics in the University of Dacca, Bengal—The Registrar, University of Dacca, East Bengal (May 31). A Ramsay Memorial fellow for chemical research—The Secretary, Ramsay Memorial Fellowship Trust, University College, Gower Street, W.C.1 (June 6). A cancer research fellow in the department of experimental pathology and cancer research of the University of Leeds—The Clerk to the Senate, The University, Leeds. A woman lecturer in biology and nature study at the Norwich Training College—The Principal. A lecturer in geography at the Lincoln Training College—The Principal. A senior biology mistress at the Cheltenham Ladies' College—The Principal. A head of the chemical department of the Leicester College of Technology—The Registrar. A junior assistant in the Experimental Stores department of the Experimental Station, Porton — The Commandant.

Our Astronomical Column.

COMETS.—Two further observations of Stearns's comet have come to hand, as follows; they are for the equinox of 1927·0:

U.T.	R.A.	S. Decl.	Observer.	Place.
Mar. 14·08354	$15^h\ 15^m\ 6{\cdot}6^s$	6° 11′ 54″	Möller	Copenhagen.
15·15479	15 14 46·5	5 51 26	Vinter-Hansen Struve	Babelsberg.

The following orbit by Mr. L. E. Cunningham has been telegraphed from Harvard and distributed by the I.A.U. Bureau :

T 1927 Sept. 6·200 U.T.

$$\left.\begin{array}{lrr}\omega & 48^\circ & 59' \\ \Omega & 214 & 54 \\ i & 92 & 29\end{array}\right\}1927{\cdot}0$$

log q 0·50406

It would appear that some error has been made in telegraphing Ω, as the above orbit fails to represent the observations. A correction of about + 14′·6, making it 215° 8′·6 is indicated.

Mr. Moller has computed the following ephemeris from the uncorrected orbit; it is for 0^h, and the R.A. is likely to need a correction of about $+1^m$:

	R.A.	Decl.		R.A.	N. Decl.
Mar. 20.	$15^h\ 11^m\ 36^s$	4° 6′ S.	Apr. 13.	$14^h\ 53^m\ 52^s$	5° 24′
28.	15 7 8	1 9 S.	21.	14 45 32	8 49
Apr. 5.	15 1 8	2 3 N.	29.	14 36 23	12 10

The orbit is still very uncertain, owing to the slow motion and the shortness of the observed arc. If it is approximately correct the brightness is likely to increase considerably, but the comet will not attain naked-eye visibility.

The following positions of comet Pons-Winnecke are by Prof. G. van Biesbroeck :

U.T.	R.A. 1927·0.	N. Decl.	Mag.
Feb. 27·26042	$14^h\ 6^m\ 58{\cdot}69^s$	24° 28′ 17″·5	17
Mar. 3·43021	14 12 20·42	25 45 23 ·7	16·5
4·30822	14 13 24·72	26 2 29 ·5	16·2

FIREBALL OF MAR. 1.—Mr. W. F. Denning writes: "There was a splendid meteor on Feb. 25 just before midnight, and another, scarcely less luminous and striking, appeared on Mar. 1, at 5.44 A.M. The latter has, however, received little comment for, like many others which pass almost unrecorded, it came at a time when people generally are asleep. The meteor was described by an observer at Staines as a huge green star with a tail of fire. At Peckham it was seen as a large green fireball with a vivid light and leaving a shower of sparks. There are six observations, including reports from Winchester and Hoddeston, Herts. The radiant point appears to have been in the Lynx or northern region of Gemini, and the height of the meteor 72 to 50 miles above the region of Hertford to near St. Valery on the French coast. One observer estimated the apparent diameter of the head of the meteor as a half that of the moon's diameter; another thought it equal in size to a tennis ball, but all agree as to the great intensity of its light and the startling effect of its sudden apparition."

PROPER MOTIONS OF FAINT STARS.—There have been many recent determinations of the proper motions of faint stars by photography. In *Mon. Not. Roy. Astr. Soc.* for Dec. 1926, Dr. W. M. Smart analyses the proper motions of 3029 stars from photographs taken with the Sheepshanks equatorial at Cambridge at an interval of twenty-two years. The apices of the two drifts are found as : Drift I, α 88°, $\delta - 12°$; Drift II, α 289°, $\delta - 73°$. The latter δ is farther south than other determinations. The position of the solar apex is found as α 273°·2, $\delta + 43°{\cdot}6$. The R.A. is in good accord with the accepted value, the declination is some 14° farther north. The speed of the solar motion agrees closely with that found by Prof. Eddington from the much brighter stars in Boss's Catalogue.

Dr. H. Knox Shaw gives in *Mon. Not.* for Jan. 1927 a list of 17 large proper motions of faint stars in the Kapteyn selected areas. They are all more than 10″ a century: the largest amounts to 50″ a century, being that of a 15th magnitude star in R.A. $5^h\ 9^m\ 44^s$, N. decl. 60° 24′ (1900). It should be worth while to examine this star for parallax. It is probably an extreme dwarf.

Research Items.

CHINESE FRESCOES FROM HONAN.—Frescoes described as "the most important works of art that have ever come out of China" have recently been acquired by the Museum of the University of Philadelphia and are figured and discussed by Miss Helen E. Fernald in the *Museum Journal* (Philadelphia), vol. 17, No. 3. Up till a few years ago it was thought that the great frescoes of the temples and palaces of the T'ang dynasty extolled in Chinese literature had long perished. Various expeditions to Turfan and the borders of western China had, however, discovered fragments of paintings unquestionably of this period, but showing signs of provincial workmanship. In 1925 the Museum acquired five mural paintings from a cave temple in Honan; but these, and others which appeared in America and Europe at the same time, were merely single figures cut from the walls and without definite data. They did no more than prove that early frescoes did still exist in China. Three panels have now been acquired which belong together and form part of an enormous picture which must have been at least forty feet long and twenty-five feet high, and of which the composition can be reconstructed with some probability. Of the three panels, the central represents Sakyamuni seated on a dais in the *pādmasana* position, with legs crossed and each foot resting on the opposite leg, sole uppermost. The left panel represents Avalokiteśvara, the Bhodhisattva of Mercy, seated in European fashion. The right-hand panel shows an important personage in robes befitting an emperor approaching the Buddha throne accompanied by a delicate female figure and followed by an official-looking individual. Two demon kings in fantastic armour are in the background. The three frescoes evidently represent three of the most important sections of a Paradise scene, such as appears again and again on the walls of caves of the Thousand Buddhas. Stylistic and other considerations assign the paintings to the latter part of the T'ang dynasty, about 845 A.D. or possibly thirty years later, and suggest as their possible source a mountain monastery of Honan.

THE ARCHÆOLOGY OF THE VALLEY OF MEXICO.—The interesting problem of the evidence for the pre-Aztec culture found beneath the lava bed of the Valley of Mexico is discussed by Mrs. Zelia Nuttal in a contribution to the *Proceedings of the American Philosophical Society*, vol. 65, No. 4. So long ago as 1861, attention was directed to fragments of pottery from beneath the lava bed, and clay heads of an archaic type have been on exhibit in the Trocadero Museum, Paris, since 1881; but their significance was not realised until investigations and excavations under the lava bed and the discovery of similar archaic heads and pottery elsewhere had revealed the existence in Mexico Valley of an archaic culture, of which an extension has since been discovered in Guatemala. It would appear from the results of recent investigation that Mexico Valley in remote antiquity was inhabited for a long period by a race which made pottery, modelled figurines, used flaked obsidian knives, and built a truncated structure faced with unworked stones. This structure was surrounded by lava flow at a period variously estimated at from 2000 to 5000 years ago. This area was the home of the *teozintl*, from which maize developed. The survivors of the catastrophe due to flood and the volcanic eruption seem to have drifted southward and to have established themselves in Guatemala, where they remained for a long period, developing the Maya and Mexican calendar. From this site they would appear to have been driven out by a catastrophe, possibly volcanic, possibly a famine due to a plague of grasshoppers, and migrated northward, carrying maize to Central America, and settled again in Mexico Valley. This hypothetical reconstruction would serve to confirm the legends and throw light on the connexion between the Maya and Aztec people, establishing the unity of their culture and their common origin.

NORWEGIAN PLANKTON INVESTIGATIONS.—The first food eaten by many young fish immediately after the absorption of the yolk consists of pelagic diatoms, and it has been suggested that the fluctuations in the supply of cod from year to year may depend on the amount of plankton food available for the young when they start to feed. Accordingly, in 1922-1925, investigations were carried out in Norway to ascertain the yearly variations in the quantity of plankton. In a preliminary report on the "Quantitative Investigations of Plankton at Lofoten, March-April 1922-1924" (*Rep. Norweg. Fish. Mar. Invest.*, vol. 3, No. 7, 1926), Birgithe Ruud traces the spring outbursts of the coastal diatoms and their connexion with the transport of dissolved nutrient matter in the snow water from the land. It is shown that the date of the spring flowering of the plankton at Lofoten depends upon the melting of the snow, for each year it follows immediately after the snow has begun to melt. The increase in the number of diatoms starts near the land and gradually spreads to offshore waters, the flowering being heralded from place to place by a lowering of the temperature and decrease in salinity, both of which are due to the increasing amount of fresh water from the snow melting on the land, on which the quantity of the developing plankton depends.

THE GROWTH OF HORNS.—The Swiss Society of Natural Sciences has published as part of its sixty-third volume (1926, pp. 1-180) an elaborate monograph by Dr. J. Ulrich Duerst on the horns of the Bovidæ (*Denkschriften der Schweizerischen Naturforschenden Gesellschaft*, Band 63. "Das Horn der Cavicornia. Seine Entstehungsursache, seine Entwicklung, Gestaltung und Einwirkung auf den Schädel der horntragenden Wiederkäuer." Zürich). Dr. Duerst holds that horn formation is primary, and that this has secondarily determined the development of a bone-core; evidence in support of this view is drawn from several examples of cutaneous horns containing a bony nodule (true os cornu). On the other hand, he denies the presence of a separate os cornu as a normal condition, but nevertheless is of opinion, from developmental evidence, that the bone-core is not a true outgrowth or apophysis but an epiphysis, which is from the beginning joined to the frontal bone. In this connexion Dr. Duerst refers at some length to the views of Gadow (*Proc. Zool. Soc.*, 1902), and although he does not consider in any detail the general problem of the relation of horns to the antlers of the Cervidæ, he appears to believe that the latter have been independently evolved. Variations in the form and structure of horns are explained in terms of their growth; of special interest are the account of the phenomenon of the shedding of juvenile horns in different species of the Bovidæ with numerous illustrated examples, and the discussion of the special case of the American prongbuck (Antilocapra), which periodically sheds its horns. An important concluding section of the monograph deals with the influence of horns on the form of the skull, a subject which

Dr. Duerst treats largely from the mechanical point of view. There are eighty figures and a full bibliography.

Insect Control in the United States.—The United States Bureau of Entomology represents the largest organisation in existence for the control of injurious insects. Under the direction of its chief, Dr. L. O. Howard, it has reached a high standard of efficiency and scientific attainment. Dr. Howard's report for the year ending June 30, 1926, has recently come to hand, and forms a record of a very wide range of activities. Among the many problems in hand, the Japanese beetle comes in for a big share of attention, and its investigation now forms a separate section of the Bureau. The perennial campaign against the Gipsy and Brown-tail moths has not been relaxed, and more than three and a half million parasites of the former insect have been liberated during the period under review. The extreme drought of 1924 extended through the cotton-growing season of 1925 and resulted in but a light infestation of the boll weevil, which has, in consequence, restricted the experimental work. The practicability of aeroplane dusting for controlling this insect has been fully borne out, and there are now several companies operating aeroplane dusting on a very extensive scale. Malaria investigations by the Bureau, and also in co-operation with other bodies, have been actively pursued. The identification of the blood imbibed by mosquitoes has led to the determination of the host relationships and preferences of various species, while a considerable amount of research has been carried out with reference to arsenical and other compounds as larvicides. Among other problems, those relating to forest insects, apiculture, and a general insect-pest survey are also reported on.

Polychæta from the Philippines.—Most of the Polychæta collected by the *Albatross* in the neighbourhood of the Philippine Islands during 1907–1909 have already been described, but in an additional paper recently published (*Bull. U.S. Nat. Mus.*, vol. 6, part 2) A. L. Treadwell makes some further records, including descriptions of one new genus and three new species. Monorchos, the new genus, is of the family Sabellariidæ, and is distinguished from allied genera by possessing only a single row of paleæ, internal to which is a series of hooks arranged in a V-shaped manner. The genotype, *M. philippinensis* n.s., is known only from a number of anterior portions brought up from 805 fathoms between Siquijor and Bohol Islands. Of the other new species, *Lætmonice nitida* n.s. is separated from *L. producta* Grube, as described by M'Intosh from the *Challenger* collections, chiefly by the form of the chætæ and by the absence of a felt covering. Two partially complete specimens are also regarded as a new species, which has been named *Eupanthalis evanida*. Some heteronereids obtained at Mindanao are thought to be *Nereis masalacensis* Grube, and a description of them is given.

Linkage in Garden Peas.—The inheritance of fifteen characters in the garden pea—the classical material of Mendel's experiments—has been studied by Miss Sverdrup (*Jour. of Genetics*, vol. 17, No. 3) on a large scale. A new mutation appeared in the experiments, having narrow leaflets frequently alternate and various flower-changes, including a narrow, pointed standard and sterile carpels. It is recessive in inheritance when the pollen is used in crosses. The main purpose of the experiments was to determine the linkages between factors. In certain cases it was found that the backcross involving two pairs of characters gave different linkage values from the F_2; or, in other words, when the cross is of the form $DR \times DR$, the crossing-over frequency is different from that of the cross $DD \times RR$. Such discrepancies in the coupling and repulsion values have been observed by other investigators in Primula, maize, and morning glories, but the explanation is not apparent. The fifteen factors of Pisum are found to fall into four linkage groups and five other independent factors, thus making nine independently assorting groups, whereas there are only seven pairs of chromosomes. One pair of the chromosomes is found to have attached satellites, which Nawaschin has shown in Crepis to be independent in the prophase of mitosis. It is suggested that possibly the structure of the chromosomes may be more flexible in Pisum than in Drosophila, where an exact correspondence has been shown between the linkage groups and the chromosome number.

Irrawaddy Delta Air Survey.—On the Burma Forest Department needing large-scale maps of the forest areas of the Irrawaddy delta, arrangements were made to undertake an air survey, since the district, which consists of densely wooded alluvial plains, did not lend itself to any other form of mapping. Progress by land is laborious, especially during high spring tides, when much of the country is submerged. The sandy sea beaches and the banks of creeks at low water afford the only lines of communication except by water. An account of the survey is given by Major C. G. Lewis in *Records of the Survey of India*, 21, 1. The area originally surveyed was about one thousand square miles, to which another 440 square miles was afterwards added. Ground control for the air survey was difficult to obtain owing to the height of the trees, which rendered useless even masts of 100 feet in length. The procedure eventually adopted was traversing along the sea beaches and triangulation along the main streams. The country was then cut up into five or six sections, each enclosed by a circuit of fixed points. The photography was begun in February and finished early in April 1924, when a total of 3795 plates had been exposed at an average elevation of 9400 feet. It is estimated that a ground survey of the delta would have occupied a party of thirty surveyors at least three years, at double the cost. The disadvantages of the air survey are that minor creeks are often obscured by overhanging trees and cannot be traced in detail on the photographs, and that it was seldom possible to photograph the coast-line at low tide, with a result that the low-tide line and many sandbanks were not surveyed.

The Echelon Structure of Japanese Volcanoes.—Under this title Sakuhei Fujiwhara presents a remarkable analysis of the distribution of volcanoes in Japan (*Gerlands Beiträge z. Geophysik*, 1927, p. 1). He defines a shear as positive when the stresses applied make a right-handed system, and as negative when they make a left-handed system, and shows by experiment that a positive shear gives a series of compression cracks in positive echelon and a complementary series of tension cracks in negative echelon. Applying this principle, it is clear that the sense of shear that has been applied to a region can be determined if the echelon cracks can be interpreted as due to tension or compression. A survey of all the Japanese volcanic lines shows that with one minor exception they are arranged in positive echelons, and that the volcanoes themselves have developed mainly along the axes of anticlines, that is, along lines controlled by compression. Thus it is deduced that the Japanese Islands are affected by a positive regional shear acting to the south-west on the Pacific side and to the north-east on the Asiatic side. The San Francisco earthquake revealed a corresponding movement on the other side of the Pacific, namely, a north-west movement of the ocean floor relative to North America. As a result of a recent study of the volcanoes of Central America, Sapper has shown that they too form a good positive echelon. It thus appears that the bed of the North Pacific is making a counter-clockwise rotation relative to the surrounding lands, and that the seismic generating force in California and Japan may be due to this rotation. No suggestion is given as to the possible origin of such a movement, but the recognition of the latter is itself a contribution to tectonic geology and geophysics of fundamental importance. The paper should be carefully studied by all who are interested in these subjects.

THE MAGNETIC MOMENT OF HYDROGEN.—On the older quantum theory, atomic hydrogen should be paramagnetic, and the moment of the atom should be the unit Bohr magneton. Any large departure from this value might have an important bearing on the new undulatory mechanics and on the idea of a spinning electron, and its experimental determination is thus a matter of considerable importance. This has now been done by T. E. Phipps and J. B. Taylor (*Phys. Rev.*, **29**, p. 309; 1927), using a modified form of the well-known apparatus of Stern and Gerlach. A pencil of hydrogen atoms was allowed to diffuse from a discharge tube through a series of narrow glass slits into a highly evacuated chamber. It was there passed through an intense inhomogeneous magnetic field, in which the atoms were orientated and deflected. They were finally registered as a simple pattern of blue lines when they impinged on and reduced a white film of molybdenum trioxide. Within the experimental error of 10 per cent., which arises largely from uncertainty as to the velocity of the atomic rays, the moment of the atom is one Bohr magneton. Active hydrogen from a tungsten filament proved to be less satisfactory, and no result could be obtained with the product of the action of ultra-violet light on a mixture of mercury vapour with hydrogen.

HIGH VOLTAGE OVERHEAD TRANSMISSION.—In the January issue of *AEG Progress*, the journal of the Allgemeine Elektricitäts Gesellschaft of Berlin, there is a timely article on high tension overhead lines. One of the troubles which electrical engineers have to overcome when using very high electrical pressures is to avoid the production of brush discharges from the line—the so-called corona discharge—as when these discharges appear there is a sudden increase in the power lost in the line and a consequent lowering of efficiency. It is known that the larger the conductors the higher is the limiting voltage at which the corona appears. This has been taken advantage of by using aluminium instead of copper for the conductors, as the larger sizes of these conductors make higher voltages possible. The A. E. G. manufactures special hollow conductors for very high voltage cables. It is pointed out that it is advisable when erecting overhead lines to make them of such size that they can, if necessary, be used for considerably higher voltages. At 220 kilovolts the diameter of the conductors must be at least 2·5 cm. if corona losses are to be avoided. It is stated that the manufacture of hollow conductors presents little difficulty. For the erection of these large wires, special tackling equipment is described. Caterpillar tractors are used to haul the necessary heavy loads over uneven ground. In the front page a photograph is given of part of a polyphase transmission line as it crosses the Main between Neuenahr and Rheinau. It is described as being for 380 kilovolt working.

THE SCATTERING OF X-RAYS.—In a recent number of the *Physikalische Zeitschrift* (No. 3, 1927) Prof. P. Debye has reprinted an important article on the scattering of X-rays by amorphous bodies, originally published by him in the *Journal of the Massachusetts Institute*. Both he and Prof. W. H. Keesom have pointed out that the interference rings obtained with liquids—similar to those produced in the powder method of crystal analysis—cannot be due entirely to the individual molecules acting as small crystals, since the patterns are very similar for different substances, and are also obtained with a liquefied monatomic gas, where the existence of a polyatomic molecule is unlikely. The principal maximum in the interference pattern has consequently been attributed to superposition of radiation scattered from molecules acting as units. If this part of the intensity of the scattered rays could be predicted as a function of the angle made with the primary ray, the residual effect, which would arise from radiation scattered by the component atoms, might give, for example, very direct information about the distance apart of the latter. Prof. Debye has given an elegant theoretical treatment for the simple case of a gas the molecule of which is a uniform sphere, and has shown that although even then the unknown Laue scattering factor has to be introduced, interference phenomena are to be expected. To a first approximation, the gross action of the molecules is proportional to the ratio of their total volume to that of the vessel in which they are contained, and so can be allowed for ideally by experimenting at different pressures. The interference pattern for a simple diatomic molecule has been worked out on similar lines, and a graphical illustration given of how it would be expected to vary with the density of the gas, the internal atomic contribution and aggregate molecular contribution being readily distinguished.

THE FORMATION OF GOLD FROM MERCURY.—A detailed account of the experiments by which the authors claim to have demonstrated the conversion of mercury into gold is given by Miethe and Stammreich in a recent issue of the *Zeitschrift für anorganische Chemie* (vol. 158, p. 185, 1926). They describe the method used in the purification of the mercury, but without detail, stating that this is unnecessary when tests show the absence of gold in the product. The mercury is distilled to a small residue, which is then treated with nitric acid and the residual gold melted with borax in a small porcelain dish. The treatment of the mercury in various ways is then described. Several types of mercury lamps are represented, although not in exact detail. The yield of gold in various experiments was very variable. In some cases no gold was found. The discharge in mercury vapour gave no gold. In a mercury turbine interrupter gold was produced and the copper electrodes after the experiments contained more gold in the outer layers than was present at the beginning. In other types of interrupters no gold was formed. Discharges between electrodes and mercury in a gas yielded negative results. Discharges between mercury and solid electrodes under paraffin oil yielded gold. The majority of the experiments gave negative results, but a connexion between positive results and the particular kind of discharge used is found. The results of other experimenters are discussed, and the conclusion is drawn that these are really in favour of the views of Miethe and Stammreich. Theoretical criticisms of their work are not regarded seriously by the latter, since they start from assumptions different from those which they themselves consider possible. They emphasise that the matter is purely an experimental problem.

The Hydrography and Geology of Umbria.[1]

In the volume before us, the Royal Italian Geological Survey has published, as the latest of its classic "Memorie descrittive," Dr. Bernardino Lotti's comprehensive work on that region which comprises the present Province of Perugia. A distinguished member of that Survey for forty-seven years, and latterly, down to the time of his retirement, director of the same, Dr. Lotti, as field geologist and chief engineer of the Mining Department, has contributed to the quarterly *Bollettino* of that Survey and other scientific periodicals as many as 200 papers, chiefly on his special sphere of central Italy, including his standard memoirs on Tuscany and the Island of Elba.

The volume was only recently completed in Dr. Lotti's retirement, in which he has now reached his eightieth year. It covers more than three hundred pages of text, with two maps and three photographic plates, and is composed of the following sections: hydrography, orography, stratigraphy, tectonic, and additional chapters on lignite deposits, mineral springs, and landslides, to which last-named the formations of Umbria are particularly liable. The stratigraphical section comprises the successive formations from the Upper Trias (Rhætian) as the oldest Umbrian Mesozoic series, to Lias, Jura, and Cretaceous, and to the Tertiary and Quaternary. The orographic and tectonic sections describe consecutively the anticlinal, longitudinally aligned, parallel Umbrian mountain and hill ranges between the mainly Tertiary Apennines and the predominantly Mesozoic Subapennines, with the synclinal depressions and valleys between them. These are the effect of earth-movements during the Miocene uprise and erosion, the tropical, marine, and lacustrine Pliocene subsidence, and the Pleistocene and more recent Quaternary uprise, which lifted the marine, estuarine, and fluvial gravels and conglomerates to heights of 300 to 1000 metres above the present sea-level. These phenomena correspond to those in the same periods in the Alps, where the Pleistocene was a period of glaciation.

The outstanding physiographic feature of Umbria is the great central Tiber basin, which in its middle or Umbrian course of eighty miles extends north to south from Città di Castello to the plain below Perugia and Assisi and thence to Todi, with the subsidiary basin of Foligno and Spoleto, and the ancient, now separated basin of Terni, the principal feeders of which are the rivers Nera and Velino. On the subject of these great ancient Umbrian, as well as the Arno basins of Tuscany, the present writer published in the *Scottish Geographical Magazine* for May and June 1919 a paper, "The Ancient Sea and Lake Basins of Central Italy," and Dr. Lotti's work deals with the Umbrian basins on similar lines.

Another outstanding feature of Umbrian hydrography are the famous Terni Marble Falls at the junction of the Velino with the Nera just above that city, the height of the vertical column—the greatest of any waterfall in Italy south of the Alps—being 160 metres and its width 20 metres. The mean volume of the Velino, of 50 cubic metres per second, is capable of producing potential energy of 80,000 horse-power, largely utilised for hydro-electric purposes. Of these historic falls Dr. Lotti's work gives a beautiful photographic view, taken by Alinari of Florence, and here reproduced (Fig. 1). The falls, which were described in the present writer's paper quoted above, are formed by three cascades, the principal upper and the two lower ones, as shown in the illustration. The large volume of the Velino is derived, besides its own drainage area in the Sybelline Mountains, from its four affluents rising in the Sabine Hills. The Marble Falls owe their name to the thick crust of travertine which covers the underlying Jurassic limestone rocks and has the appearance of polished marble.

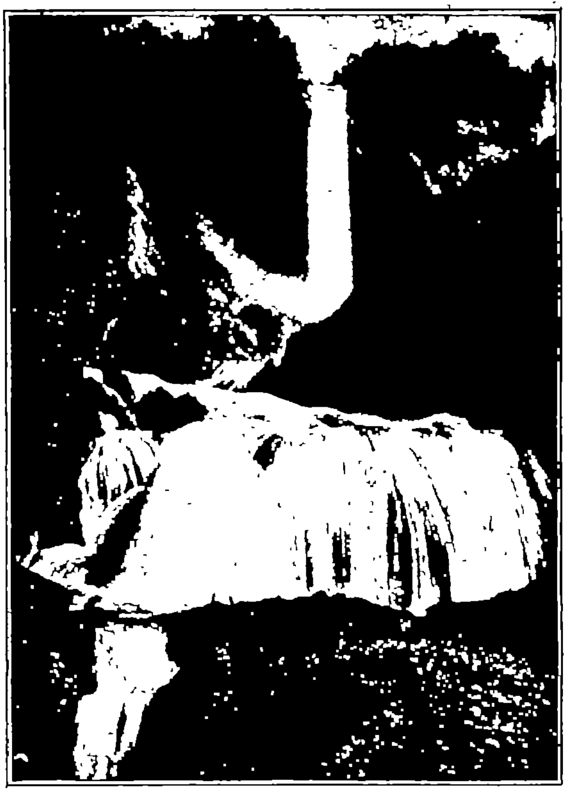

Fig. 1.—The Terni Marble Falls, Umbria.

C. Du Riche Preller.

[1] Descrizione geologica dell' Umbria. Per B. Lotti. Pubblicata per cura del R. Ufficio Geologico. (Memorie descrittive della Carta Geologica d' Italia, Vol. 21.) Pp. 320. (Roma: Provveditore generale dello Stato Libreria, 1926.) 45 lire.

Palæolithic Man in Scotland.

Until the summer of 1926 no indubitable trace of palæolithic man had been found in Scotland, if the Azilian remains of the west coast and the Tardenoisian flints scattered throughout the country be regarded as belonging to an intermediate period between the old and new stone ages. The persistent absence of palæolithic evidences has generally been ascribed either to the presence of an ice-sheet covering Scotland at a date long after such Arctic conditions had disappeared in England and Wales and to the consequent non-presence of human beings, or to the erasure of traces of palæolithic humanity deposited in a period of interglacial mildness by a later recrudescence of the ice-sheet.

During three summer months of 1926, excavations, superintended by Mr. James E. Cree, were carried out, by means of a generous grant from the Royal Society of London, in undisturbed caves in the valley of Allt nan Uamh, near Inchnadamph in Sutherland, in close proximity to the 'Bone Cave' which yielded such excellent faunistic results at the hands of Dr. Horne and the late Dr. Benjamin Peach in 1889. A preliminary report on the results of the first season's excavations was communicated by the committee responsible for the administration of the grant, Mr. J. Graham Callander, Mr. James E. Cree, and Dr. James Ritchie, to the Society of Antiquaries of Scotland at its meeting on Feb. 14.

Of the four caves in which work was carried out, the Reindeer Cave proved to be the most interesting. It contained two bone-bearing deposits, an upper cave-earth, and a lower slightly rounded gravel. The cave-earth contained many bones of still existing species of animals as well as of bears, and two human skeletons or parts of skeletons, one of which, a dolicocephalic skull, had been definitely interred, the first formal interment yet recorded from a Scottish cave. The gravel was remarkable for the vast numbers of shed and broken antlers of young reindeer which were scattered throughout the deposit, a short distance of about twenty feet yielding remains of more than four hundred individual reindeer. Associated with these were remains of other members of an Arctic fauna, and indubitable traces of man were revealed by a simple reindeer horn implement, by humanly cut and scratched reindeer antlers, by rude attempts at engraving, and by fragments of charcoal.

The evidence points to the re-sorting of the reindeer deposit in the cave by a stream, probably of seasonal melt-water, which flowed along the margin or off the surface of a valley glacier the surface of which stood about the level of the caves, 200 feet above the present bed of the stream. Further, the geological evidence, the nature of the fauna, and the state of fossilisation of the bones, all show that the deposit belongs to one of the periods of the Upper Palæolithic series, belonging to Magdalenian or earlier times. Lack of artefacts of cultural significance prevents a more definite conclusion in the meantime.

A further discovery of great interest was made in a large cave, the presence of which was unsuspected until access was gained through the clearing of a narrow vertical chimney 10 feet in depth. In the glacial silt which filled this cave almost to the roof were found bones of reindeer and arctic animals, including remains of the extinct cave-bear and arctic fox, neither of which has hitherto been found in Scotland. The geological evidence suggests that this association represents an arctic fauna present in Scotland in a period of interglacial mildness, prior to the last considerable recrudescence of the ice, and long preceding the valley glaciers of the final ice-epoch. No trace of this interglacial fauna has been definitely determined hitherto in northern Britain.

In concluding his presentation of the report on behalf of the Committee, Dr. Ritchie pointed out that further evidence is desirable, particularly as regards the cultural stage of the palæolithic people and as to the members of the cave-bear interglacial fauna, and that with the view of obtaining such evidence, excavation is to be continued during the present summer.

University and Educational Intelligence.

CAMBRIDGE.—P. Hall has been elected to a fellowship at King's College. A. F. H. Ward, Jesus College, has been elected to the Amy Mary Preston Read Scholarship.

The University Appointments Board reports that 396 men were placed in appointments in the past year, including 135 educational appointments, 80 manufacturing and technical appointments, 68 administrative appointments in commerce and industry, 51 in colonial administration, 19 in agriculture and forestry, and 7 in overseas railways, public works departments and surveys.

It is proposed to confer the title of Registrary Emeritus upon Dr. J. N. Keynes in recognition of his great services to the University during the fifteen years of his registraryship.

LONDON.—The first course of the series of Gow Lectures on the colloid chemistry of the rubber industry will be given under the auspices of the University by Dr. E. A. Hauser of Frankfort-on-Main, at University College, London (Gower Street, W.C.1) during the first fortnight in May. Full particulars of these lectures will be published later.

MANCHESTER.—Prof. H. S. Raper has been appointed Dean of the Medical School as from July next.

Among those on whom it is proposed to confer honorary degrees on Founders' Day, May 18, are Dr. C. S. Myers, Director of the National Institute of Industrial Psychology, and Prof. Richard Willstätter, formerly professor of chemistry in the University of Munich and Nobel prizeman, who are to receive the degree of D.Sc.

The Hill Prize in bio-chemistry has been awarded to Mr. Eric Boyland.

OXFORD.—A research fellowship in medical science of the value of £200 a year has been established in memory of Dr. Gustave Isidore Schorstein, of Christ Church, Assistant Physician to the London Hospital. Candidates must be graduate members of the University, whether men or women, who hold a registrable medical qualification and are less than thirty-five years of age. Fellows are to be elected, without examination, by the Board of the Faculty of Medicine. The fellowships are tenable for two years, but may be extended by the Board for one further year.

ST. ANDREWS.—A benefactor, who desires his name to be withheld, has offered the sum of £100,000 in appreciation of the progress made in development of the university. Of this sum, £40,000 is to be set aside for the purpose of founding residential entrance scholarships, each of the annual value of £100. These scholarships are to be confined to men students of the United College, and the condition is attached that the holders must reside in an official residence in St. Andrews. Five such scholarships will be open for competition each year, and the first appointments will be made before the beginning of next academical year. Towards the cost of the new Residence Hall for men students, £29,000 has been allocated; the sum of £8000 is to be devoted to the improvement of the University Chapel, and the remainder of the gift, amounting to £23,000, is left at the disposal of the University Court.

An additional contribution of £12,000 on behalf of the Residence Hall has been announced, and Lord Inchcape has given £5000 for the same purpose. Together with other gifts and the £20,000 awarded by the Carnegie Trust as part of the quinquennial allocation to the University, the funds at the disposal of the Court for the building of the residence amount to £70,000. It has been resolved to proceed at once with the scheme.

THE committee of the Leplay House Tours Association is arranging to take two groups of students and others on to the Continent during the coming Easter vacation. One party will go to the Auvergne, a centre of interest to geographers, geologists, and botanists, and the other to Dalmatia, a visit of special interest to students of archæology, history, and sociology. Full darticulars can be obtained from Miss Margaret E. Tatton, Leplay House, 65 Belgrave Road, London, S.W.1.

Calendar of Discovery and Invention.

March 27, 1827.—A hundred years ago, on Mar. 27, 1827, Darwin, then just eighteen years of age and a medical student at Edinburgh, contributed to the Edinburgh Plinian Society a paper on the larvæ of the Flustra or sea-mat, one of the Polyzoa.

March 27, 1895.—After making known the discovery of argon, Ramsay, through a suggestion of Sir Henry Miers, made experiments with the mineral cleveite, which it was thought would contain a compound of argon. From these experiments he was led to the isolation of helium, detected by Lockyer in the sun in 1868, but hitherto unknown on the earth. This discovery was made known on Mar. 27, 1895, at the annual meeting of the Chemical Society, the *Transactions* of which contain Ramsay's account of his investigations.

March 27, 1899.—The first wireless message across the English Channel was sent on Mar. 27, 1899. With an aerial erected on Dover Town Hall, signals were sent to Wimereux, near Boulogne, 32 miles distant, this being the record distance for wireless telegraphy up to that time.

March 29, 1810.—The modern printing machine can be traced back to Friedrich König, a printer of Leipzig. König visited England in 1806, and four years later, on Mar. 29, 1810, took out the first of four patents for printing machines in which he employed revolving cylinders. The *Times* was first printed by König's machines on Nov. 14, 1814, while the first book printed by machinery was Blumenbach's "Physiology."

March 31, 1795.—The hydraulic press so extensively used to-day was described by Bramah in his patent of Mar. 31, 1795, and his demonstration apparatus is preserved in working condition at the Science Museum, South Kensington. Pascal, 150 years previously, had, however, stated the principle of the machine. If a vessel, he said, had two openings, one a hundred times as large as the other, and if each be supplied with a piston which fit it exactly, then a man pushing the small piston will equilibrate that of 100 men pushing the larger piston.

March 31, 1889.—Commenced on Jan. 28, 1887, the Eiffel Tower in Paris, the highest structure in the world, was completed on Mar. 31, 1889. Its height is 300 metres and its weight 6875 tons.

April 1, 1823.—On April 1, 1823, the Treasury requested the opinion of the Royal Society on the merits and utility of a plan submitted by Babbage for applying machinery to the purpose of calculating and printing mathematical tables. This referred to the "difference engine" invented by Babbage in 1812. Its construction was authorised in 1823, suspended in 1833, and abandoned in 1842, after the Government had provided about £17,000 and Babbage had expended some £6000 of his own. This and many other calculating machines are now to be seen in the mathematical collections at the Science Museum, South Kensington.

April 2, 1799.—For more than seven centuries the home of Benedictine monks, the Priory of Saint Martin-des-Champs, Paris, in 1790 was appropriated by the French nation, and on April 2, 1799, became the home of the Conservatôire des Arts et Métiers, instituted by law on Oct. 10, 1794.

April 2, 1845.—The photographic study of the sun may be said to have been begun in 1858 with De la Rue's 'photo-heliograph,' but thirteen years before that, on April 2, 1845, Foucault and Fizeau obtained a daguerreotype of the sun which was reproduced in his "Popular Astronomy" by Arago, at whose suggestion the experiment was made.

E. C. S.

Societies and Academies.

LONDON.

Royal Society, Mar. 17.—**W. L. Bragg** and **J. West**: The structure of certain silicates. In a number of compounds the oxygen atoms are arranged in one of the forms of closest packing, the atoms of metal or silicon being inserted into this oxygen assemblage and causing only a slight distortion of its ideal arrangement. Typical examples are the compounds Al_2O_3, $BeAl_2O_4$, $MgAl_2O_4$, Mg_2SiO_4, $MgCaSiO_4$, $(MgOH)_2Mg_3(SiO_4)_2$, Al_2SiO_5 (kyanite). In the diffraction of X-rays by these crystals, which are often characterised by low symmetry and large unit cell, the simple pattern produced by the oxygen arrangement is evident, superimposed upon the pattern produced by the crystal as a whole. Other silicates are based upon more complicated arrangements of oxygen atoms, but these atoms appear in all cases to play a highly important part in determining the structure.

W. A. Wooster: The analysis of beams of moving charged particles by a magnetic field. The intensity distribution in the line produced by a magnetic field acting on a beam of homogeneous particles is determined (*a*) for a source of particles which is infinitely narrow, and (*b*) for sources of various finite widths. The conditions under which the analysis of moving charged particles is most favourably carried out are derived from this structure of the lines. The method can be applied to the determination of the velocity distribution of particles passing through thin sheets of matter.

J. F. Spencer and **E. M. John**: The magnetic susceptibility of some binary alloys. The magnetic susceptibility of the pure metals gold, silver, lead, tin, bismuth, aluminium, and cadmium, and a complete series of binary alloys of lead with gold, silver, and tin; tin with aluminium, bismuth, gold, and cadmium; and gold with cadmium have been measured by means of a Curie balance. The susceptibility-composition curves indicate the existence of some intermetallic compounds which have not previously been recognised, for example, Al_4Sn_2, Ag_5Pb_2, and Sn_4Bi_3; they confirm the existence of some other compounds, for example, Pb_3Au_2, $AuSn_2$, $AuCd_3$. The curves and measurements show that the alloy of lead and silver containing 29 per cent. of lead is comparatively strongly paramagnetic, that of lead and gold containing 94 per cent. lead is strongly diamagnetic, and the aluminium-tin alloy containing 75 per cent. of tin is also strongly diamagnetic. The susceptibilities of the lead-tin alloys, where compounds are not formed, may be calculated by the mixture rule.

H. T. Flint and **J. W. Fisher**: A contribution to modern ideas on the quantum theory. An account is given of the four-dimensional aspect of de Broglie's phase wave, followed by a suggestion for the inclusion of quantum phenomena into the general theory of relativity by the introduction of a four-vector, to complete the current four-vector of electrodynamics, of which the divergence does not vanish. This leads by a simple assumption to a generalised form of Shrodinger's wave equation.

Royal Meteorological Society, Feb. 16.—**J. Glasspoole**: The variability of average monthly rainfall throughout the year. The variability of the monthly averages for the thirty-five years, 1881–1915, has been circulated for some 550 stations in two ways. In (1) the range has been used, *i.e.* the difference between the largest and smallest monthly averages. It varies from 1 inch at stations along the east coast and in central England, to 9·8 inches at both Glenquoich, in the western Highlands of Scotland, and

Seathwaite, in the English Lake District. The equation $R = -0{\cdot}14 + 19M + 41M^2$ represents fairly closely the variation of the range (R) with the mean rainfall per day (M) in all parts of the British Isles. In (2) the monthly averages have been expressed as 'mean rainfalls per day.' The mean deviation of these amounts, as a percentage departure from the mean for the twelve monthly values, varies from 11 per cent. in central England to more than 25 per cent. in Dartmoor, the Lake District, parts of Wales, and the western Highlands of Scotland. The distribution in this case presents features unlike that of the map of the average annual rainfall.—**L. F. Richardson** and **Denis Proctor**: Diffusion over distances ranging from 3 km. to 86 km. This paper describes the way in which air is scattered and mixed by the eddies in the wind. In order that the wandering of a piece of air may be observed, the air must have some mark carried with it; small free balloons have been used and also volcano ash. The statistics of the observed scatter may be of interest in connexion with factory smoke and town planning. The rate of diffusion has been observed by various authors for air masses ranging in size from a few metres to 1000 kilometres, and comparison of their results shows that Fick's law does not describe atmospheric diffusion.

CAMBRIDGE.

Philosophical Society, Feb. 28.—**G. C. Steward**: On Herschel's condition and the optical cosine law. Sir John Herschel investigated the condition which would ensure the vanishing of spherical aberration for the region, upon the axis of an optical system, in the neighbourhood of two conjugate axial points, themselves free from aberration; but Herschel's condition applies only to first order, or primary, aberration, *i.e.* to aberration depending upon the cube of the inclination of the ray to the axis of symmetry. Abbe, later, gave a more general condition which is shown to imply the stationariness of spherical aberrations of *all* orders. A geometrical proof is given of a very general theorem recently published by T. Smith under the name of the optical cosine law. This law is valid in the presence of any combination of the geometrical aberrations, as well for a symmetrical as for an unsymmetrical optical system.

PARIS.

Academy of Sciences, Feb. 14.—**Maurice Hamy**: A particular case of diffraction of solar images.—**P. Villard**: The chemical actions of radiations. A description of experiments in which two halves of the same plate are exposed to ordinary light and to X-rays, with a discussion of the meaning of the results obtained. Contrary to the view generally admitted, the properties of a latent image vary with the frequency of the radiation to which the plate has been submitted.—**de Sparre**: Remarks on a recent note published by H. Sugot. A re-assertion of priority.—Prof. John Townsend was elected a *correspondant* for the section of physics in succession to Pierre Weiss, elected non-resident member.—**Bertrand Gambier**: Surfaces having a ds^2 of Liouville and their closed geodesics.—**P. Noaillon**: An isolated non-critical singular point of a harmonic function.—**R. Gasse**: A special class of equations of the form $s = f(x, y, z, p, q)$.—**Octave Onicescu**: Adjusting an aggregate of values, and its applications to the representation of functions by series of functions and to integral equations.—**Hasso Harlen**: The logical paradox in the theory of ensembles.—**P. Dupont**: Calculation of the frictional forces on the profiles of wings.—**Pierre Dive**: The impossibility of an ellipsoidal stratification of a heterogeneous fluid in rotation.—**R. Wavre**: Figures of equilibrium, the stratification of the planets and the equation of the first species.—**Gaston Dupouy**: A direct reading apparatus for the measurement of magnetic fields. A gaussmeter. A crystal of siderose (iron carbonate) is mounted so that the geometrical axis of rotation of the apparatus is perpendicular to the plane containing the ternary axis of the crystal and the direction of the lines of force. The couple produced by the magnetic field is balanced by the torsion of a wire or spiral spring. The apparatus is graduated by direct comparison with a flux meter of the usual type. Measurements can be made very quickly, but with the drawback that there is a correction for temperature.—**A. Cotton**: Remarks on the preceding communication.—**Pierre Chevenard**: The anomaly of the internal friction of reversible ferronickels.—**A. P. Bigot**: Some anhydrous silicas containing clay. The composition of ochres.—**Paul Gaubert**: The dehydration and hydration of some platinocyanides.—**J. Thoulet**: Densimetry in the Tyrrhenian Sea.—**Besson**: Comparative observations of the light radiation at the sea coast and in the interior.—**Jean des Cilleuls**: The phytoplankton of the Thouet, a tributary of the Loire.—**A. Maige**: Observations on the various modes of digestion of starch grains in plant cells. The two modes of digestion of starch grains, peripheral or internal, are related to the presence or absence of a plastial crust, possessing an adhesive property for the amylase.—**Volmar** and **Samdahl**: Kirondrine, the bitter and toxic principle of Kirondro seeds (*Perriera madagascariensis*). A crystalline substance has been isolated from Kirondro seeds (0·75 per cent. of seed). It does not appear to be an alkaloid, neither does it give the reactions of a glucoside. Its chemical composition is being investigated.—**A. Gruvel**: Raising *Salmo Pallaryi* in Morocco.—**Mlle. F. Coupin**: The index of cerebral value in infancy in the anthropoids.—**M.** and **Mme. Lapicque**: Concentration of the cellular juices in the higher fungi.—**L. Bounoure**: Has ovular supermaturation an influence on the origin of the primary gonocytes in *Rana temporaria*?—**Edouard Fischer**: The upper limit of distribution of various organisms in very calm water.—**A. Blanchetière**: The composition of the peptones. Description of a method for separating and determining peptides and diacipiperazines, and determinations of the proportions of the latter in various specimens of commercial peptones.—**E. Aurel**, **L. Genevois**, and **R. Wurmser**: The apparent potential of solutions of reducing sugars.—**Paul Hauduroy**: Diphtheric toxins giving rise to a diphtherimorph bacillus. A specimen of diphtheric toxin, preserved in the dark for two years, contained filtrable bacilli from which, by a series of plate cultures, visible organisms were obtained possessing the morphological characters of the diphtheria bacillus; but *without pathogenic action* (guinea-pig).—**R. Sazerac**, **Hirosi Nakamura**, and **Mme. M. Kitchevatz**: The action of bismuth on hæmorragic icterus. Bismuth, as sodium tartarobismuthate, possesses a remarkable preventive action towards infection by *Spirochæta icterohæmorragiæ* in the guinea-pig, and also has marked curative action on the evolution of the disease caused by this organism.

ROME.

Royal Academy of the Lincei, Jan. 2.—**V. Volterra**: Biological fluctuations.—**C. Somigliana**: The relations existing between the geodetic constants and the values of gravity. Development of Pizzetti's expression for gravity on the surface of the ellipsoid of rotation leads to the conclusion that there exists a homogeneous linear relationship between any three values of gravity on such a surface. The same expression gives rise to a biquadratic equation which determines the eccentricity as a function of any three values of gravity and of their corresponding latitudes.—U. Cisotti: A noteworthy exception to the Kutta-Joukowski theorem.—F. Millosevich: The corundum rocks of Val Sessera.—L. Petri: The method of applying Wood's light in investigations on vegetable pathology. Attention is directed to the existence of a peculiar luminogenous substance, which appears to be present in all living vegetable tissues, even in potato tubers, although the photograms of the green tissues are by far the more luminescent. The crude alcoholic extract of chlorophyll gives a photogram with a wine-red fluorescence, whereas the photogram of chlorophyll-free leaf tissue is only moderately fluorescent. Dilute sulphuric acid does not modify the luminogenic properties, and the substance in question diffuses rapidly by capillarity into filter paper.—S. Baglioni, L. Bracaloni, and A. Galamini: Physiological action of alcohol. Variations in glucohæmia and alcoholæmia resulting from ingestion of alcoholic liquors and of saccharose (ii). The results of experiments on human beings reveal a connexion between glucohæmic and alcoholæmic variations which appears to support, in part at least, the hypothesis advanced by Ford and recently maintained by Serono, that sugar ultimately undergoes alcoholic scission in the organism.—F. De Carli: Anhydrous borates of silver, barium, and zinc. The results of measurements of the temperature of devitrification of systems composed of boric anhydride and silver oxide, barium oxide, and zinc oxide respectively indicate the existence of anhydrous borates having the formulæ: $Ag_2O, 4B_2O_3$; BaO, B_2O_3; $BaO, 2B_2O_3$; $BaO, 3B_2O_3$; $BaO, 4B_2O_3$; $2ZnO, B_2O_3$, and ZnO, B_2O_3.—C. Jucci: Heredity of the metabolic type in silkworms. Larval development in reciprocal crosses between two races of *Bombyx mori*.—E. Benedetti: The telencephalon of the triton. Contribution to the comparative study of the central nervous system of amphibia.

Diary of Societies.

SATURDAY, MARCH 26.

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (South-Eastern District Meeting) (at Guildhall, Rochester), at 11 A.M.

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (South Midland District Meeting) (at Leighton Buzzard), at 11 A.M.—H. J. Barnes: Waterworks.—B. H. Robjant: Housing Schemes.

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (North-Eastern District Meeting) (at Town Hall, South Shields), at 2.15.—J. Reid: Estimation of Storm Water Discharge.

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (Yorkshire and North-Western Districts) (at Town Hall, Manchester), at 2.30.—R. Bruce and others: Discussion on Manchester and District Joint Town Planning Report.

Geologists' Association (at Museum of Practical Geology), at 2.30.—Demonstrations:—Fossil Plants from the Coal Measures, by Dr. R. Crookall.—Goniatite Zones of the Millstone Grit of Central Lancashire, by S. W. Hester.—Fossils from the Neighbourhood of Leighton Buzzard, by J. Pringle.

Royal Institution of Great Britain, at 3.—Sir Ernest Rutherford: The Alpha Rays and their Application to Atomic Structure (2).

North of England Institute of Mining and Mechanical Engineers (at Neville Hall, Newcastle-upon-Tyne), at 3.—R. White: The Ventilation of a Pyrites Mine, with special reference to Fire-fighting, Safety and Rescue Work.—Papers open for Further Discussion:—Dry Cleaning of Coal, by J. S. Carson; Conveyors and Conveying Systems, by W. Britton.

Hull Association of Engineers (at Municipal Technical College, Hull), at 7.15.—A. R. Clemitson: Water Tube Boilers and Pulverised Fuel.

MONDAY, March 28.

Royal Society of Edinburgh, at 4.30.—Dr. H. H. Read: The Igneous and Metamorphic History of Cromar, Deeside, Aberdeenshire.—A. Calder: The Rôle of Inbreeding in the Development of the Clydesdale Breed of Horses.—Prof. W. Peddie: Magnetism and Temperature in Crystals.—Miss W. J. Smith: After Images of Coloured Sources.—Y. Tamura: The Effects of Implantation upon Ovarian Grafts in the Male Mouse.

Institute of Actuaries, at 5.—C. F. Trustam: On a New Method of Calculating Model Office Reserves.

Royal College of Surgeons of England, at 5.—C. E. Shattock: Demonstration of Veins and Lymphatic Vessels.

Institution of Electrical Engineers (North-Eastern Centre) (at Literary and Philosophical Society, Newcastle-upon-Tyne), at 7.—W. B. Whitney, C. E. R. Bruce, and E. B. Wedmore: The Number of Tests required to establish the Rupturing Capacity of an Oil Circuit-Breaker.

Institution of Mechanical Engineers, at 7.—Sir John E. Thornycroft: Torpedo Boats and their Machinery (Annual Lecture).

Royal Society of Arts, at 8.—G. I. Finch: Some Industrial Applications of Electrothermics (Cantor Lectures) (3).

Royal Society of Medicine (Odontology Section), at 8.—D. Stewart: Some Aspects of the Innervation of the Teeth.—T. B. Layton: Osteomyelitis of the Maxilla in Scarlet Fever.

TUESDAY, March 29.

Royal Society of Arts (Dominion and Colonial Meeting), at 4.30.—J. H. Oldham: Tendencies in African Native Education.

Royal Aeronautical Society, at 5.—Annual General Meeting.

Royal College of Physicians of London, at 5.—Sir Charles Briscoe, Bart.: The Muscular Mechanism of Respiration and its Disorders (Lumleian Lectures) (3).

Royal Institution of Great Britain, at 5.15.—Prof. J. W. Cobb: Some Properties of Coke (1).

Hull Chemical and Engineering Society (at Grey Street, Hull), at 7.45.—R. B Foster: Works Filtration.

WEDNESDAY, March 30.

Faraday Society (at Chemical Society), at 3.—Dr. W. H. J. Vernon: The Second Experimental Report to the Atmospheric Corrosion Research Committee of the British Non-Ferrous Metals Research Association.

Newcomen Society for the Study of the History of Engineering and Technology (at 17 Fleet Street), at 5.30.—Dr. A. Raistrick: Notes on Lead Mining and Smelting in West Yorkshire.

Liverpool Engineering Society (at 9 The Temple, Liverpool), at 6.—Dr A. McCance: Properties of Steel at High Superheated Temperatures.

Institution of Civil Engineers (Students' Meeting), at 6.30.—V. F. Cornish: The London County Council Becontree Housing Estate.

Institution of Electrical Engineers (South Midland Centre) (at Birmingham University), at 7.—F. H. Clough: The Stability of Large Power Systems

Eugenics Society, at 8.

THURSDAY, March 31.

Royal Society, at 4.30.—Sir Robert Hadfield: Alloys of Iron and Manganese of Low Carbon Content.—Dr. E. Griffiths: The Thermal and Electrical Conductivity of a Single Crystal of Aluminium.—W. L. Webster. The Transverse Magneto-Resistance Effect in Single Crystals of Iron.—*To be read in title only*:—Prof. W. A. Bone, R. P. Fraser, and F. Witt: The Initial Stages of Gaseous Explosions. Part III. The Behaviour of an Equimolecular Methane-Oxygen Mixture when Fired with Sparks of Varying Intensities.—F. T. Meehan: The Expansion of Charcoal on Sorption of Carbon Dioxide.—J. F. Lennard-Jones and W. R. Cook: The Equation of State of a Gaseous Mixture.

Royal Institution of Great Britain, at 5.15.—H. J. E. Peake: The Beginnings and Early Spread of Agriculture (1).

Child-Study Society (at Royal Sanitary Institute), at 6.—Mrs. Leah Manning: American Ideals in Education.

Institution of Electrical Engineers, at 6.—W. McClelland: The Applications of Electricity in Warships.

Royal Aeronautical Society (at Royal Society of Arts), at 6.30.—Dr. E. G. Richardson: Recent Model Experiments in Aerodynamics.

Society of Chemical Industry (Manchester Section, jointly with North-Western Branch of Institution of Mechanical Engines) (at Engineers' Club, Manchester).—Dr. W. R. Ormandy: Lubrication.

FRIDAY, April 1.

Royal College of Surgeons of England, at 5.—Sir Arthur Keith: Demonstration of the Anatomy and Physiology of the Gall Bladder.

Society of Chemical Industry (Chemical Engineering Group, jointly with Institution of Mechanical Engineers) (at Institution of Mechanical Engineers), at 6.—A. G. Marshall and C. H. Barton: Lubricating Oils—Laboratory Tests in relation to Practical Results.

Institution of Civil Engineers, (Birmingham and District Association) (at Chamber of Commerce, Birmingham), at 6.—H. R. J. Burstall: The Testing of Heat Engines.

Society of Chemical Industry (Manchester Section) (Annual General Meeting) (at 16 St. Mary's Parsonage, Manchester), at 7.—Dr. W. Rosenhain: The Work of the National Physical Laboratory.

Institution of Locomotive Engineers (at Engineers' Club, Coventry Street, W), at 7.—A. M. Bell: Tare and Load compared in Modern Locomotives and Rolling Stock.

Institution of Mechanical Engineers (Informal Meeting), at 7.—Major A. W. Farrer: British Empire and Overseas Trade.

Royal Photographic Society of Great Britain, at 7.—Pictorial Group Meeting.

Photomicrographic Society (at 4 Fetter Lane), at 7.—E. Cuzner: Stereoscopic Photomicrography.

West of Scotland Iron and Steel Institute (at Royal Technical College, Glasgow), at 7.—Annual General Meeting.

Junior Institution of Engineers, at 7.30.—G. J. Hartley. Notes on the Production of Saltpetre.

Geologists' Association (at University College), at 7.30.—Dr. A. Kingsley Wells: The Geology of the Dolgelley District.

Philological Society (at University College), at 8.—N. B. Jopson: Judæo-Spanish Notes.

Royal Institution of Great Britain, at 9.—J. Allen Howe: The Stones of London.

SATURDAY, April 2.

Royal Institution of Great Britain, at 3.—Sir Ernest Rutherford: The Alpha Rays and their Application to Atomic Structure (3).

PUBLIC LECTURES.

SATURDAY, March 26.

Horniman Museum (Forest Hill), at 3.30.—M. A. Phillips: Wild Life in Meadow, Stream, and Wood.

SUNDAY, March 27.

Guildhouse (Eccleston Square), at 3.30.—Very Rev. Dr. J. H. Hertz (Chief Rabbi): Fundamental Ideals and Proclamations of Judaism.

WEDNESDAY, March 30.

Fulham Central Public Library, at 8.—M. C. Pink: The London Telephone Service.

THURSDAY, March 31.

Fulham Central Public Library, at 8.—S. C. Freeman: Flowers for London Gardens.

SUNDAY, April 3.

Guildhouse (Eccleston Square), at 3.30.—Prof. J. P. Bruce: Confucianism.

CONFERENCE.

March 29, 30, and 31.

Royal Microscopical Society (at Liverpool University).—Prof. C. O. Bannister: Demonstration of the Use of the Microscope in the Examination of Surface Structure of Metals and in the Detection of the various Platinum Metals in Silver Beads.—J. E. Barnard: Recent Advances in Medical Microscopy.—Conrad Beck: The Best Method of Illumination of Metallurgical Specimens with Vertical Illuminator.—Mrs. Bisbee: A Method for Demonstrating Certain Features in the Anatomy of Flat Worms.—Dr. W. B. Cooke and C. F. Hill: Pneumo-koniosis due to Asbestos Dust.—R. J. Daniel: Note on a Method of Staining and Clearing Muscular Systems of Crustacea.—I. S. Double: The Microscopic Characters of Certain Horizons of the British Chalk.—Prof. J. Bronte Gatenby: Golgi Apparatus, and Idiosome: a Critique of Parat's Vacuome Theory.—Prof. R. Ruggles Gates and Dr. J. Latter: Meiotic Phenomena in Lathræa.—H. Hurrell: The Ecology of Freshwater Polyzoa in East Anglia.—Dr R. J. Ludford: The Cytology of Secretions.—Dr. James A. Murray: Experiments in Stereo-Photomicrography.—Dr. Eric Ponder: The Diameter of the Red Cells of Man before and after Exercise.—Prof. W. Ramsden: Demonstration on Surface Tension.—J. Ross-Mackenzie: Causes and Correction of Cloudiness in Malted Liquors.—Dr. A. C. Thaysen and H. J. Bunker: Some Observations on the Microscopical Study of Deteriorated Fabrics from Early Egyptian Tombs.—Harold Wrighton: The Photomicrography of Metals.—J. E. Barnard, Conrad Beck, Dr. W. J. Elford, Dr. G. M. Findlay, Dr. J. E. McCartney, and John Smiles will take part in a discussion on Filterable Viruses and the Limits of Microscopic Visibility.

A Popular Lecture will be delivered on Thursday evening, March 31, at 8 P.M., in the Arts Theatre of the University by Prof. J. Arthur Thomson on The Microscopy of Everyday Life.

COMMEMORATION.

April 1.

Lister Centenary (at Glasgow).

CONGRESSES.

April 20 to 24.

Journées Médicales Marseillaises et Coloniales (at Marseilles).—Prof. Cantacuzène: The Rôle of the Streptococcus in the Etiology of Scarlet Fever.—Dr. Mayer: Recent Advances in the Treatment of Cancer.—Prof. Ottolenghi: Malaria.—Dr. N. Bernard: Beri-beri.—Prof. Imbert: Bone-grafting.

April 25 to 28.

German Society for Internal Medicine (at Wiesbaden).—Discussions on Psychotherapy, introduced by Gaupp and Fleischmann; Results of Recent Functional Investigations of the Stomach and Duodenum, introduced by G. Katsch.—A joint meeting with the German Rontgen Society will be held on April 28, with a discussion on the Significance of Rontgen-ray Examination of the Lungs and Mediastinum for Internal Medicine (excluding Tuberculosis), introduced by Distlen, Assmann, Haenisch and Lorey, and Fleischner.

SATURDAY, APRIL 2, 1927.

Scientific Slaughtering.

THE problem of the humane slaughtering of animals for food is one which has exercised many members of the medical and veterinary professions. It is of direct concern to men of science, first because certain relevant facts which are in dispute can only be settled by rigorously scientific experiment, and secondly, because the ethical principles involved have received a much enhanced significance from the work of Darwin and other zoologists. The discussion recently opened at King's College, London, by Profs. McCunn and Smythe, of the Royal Veterinary College, under the chairmanship of Prof. Julian Huxley, affords an occasion for putting before the readers of NATURE the more important of the facts relating to the slaughterhouse.

In all matters which involve a conflict between ethical principles and economic interests the relevant facts are apt to become entangled in a good deal of special pleading, and in the present case there are certain points upon which even scientific authorities are not in agreement; but although the necessity for further inquiry of a rigorously scientific character is generally recognised, a number of important facts may be regarded as definitely established. The most recent authoritative documents for these are the reports issued by the London County Council on Feb. 15, 1923, and by the Public Health Department of the Corporation of London on April 2, 1925. Considerable importance attaches also to a paper read by Prof. G. H. Wooldridge before a meeting of the National Veterinary Medical Association and published, together with the discussion which followed it, in the *Veterinary Record* of Mar. 4, 1922; and to a report on the Jewish method of slaughtering by Prof. E. H. Starling and Sir Michael Foster, published by the Admiralty in 1904. The views of the meat traders were defended by Prof. Leonard Hill in the *Lancet* of Dec. 22, 1923, but the results of the demonstration arranged by them at Birmingham in November 1923 should be accepted with considerable reserve, so far, at all events, as the question of bleeding is concerned, since (according to Dr. W. J. Howarth, Medical Officer of Health to the Corporation of London) animals were "left on the floor for different intervals before the blood was allowed to be extracted." This incident emphasises the necessity for ensuring that such trials be controlled in every detail (including, by the way, the selection of the animals) by men trained in the rigour of scientific method.

The old-fashioned methods of slaughtering which are employed in the case of about fourteen million animals yearly in Great Britain are broadly as follows: Large animals before being killed are stunned with a poll-axe; pigs are hoisted with a chain attached to one hind leg and stuck, commonly without previous stunning; many calves and some pigs are first stunned with a hammer; occasionally sheep and lambs are similarly stunned, but usually they are lifted on to a 'crutch' or trestle and stuck with a knife while conscious, after which their necks are broken by pressing back the head, the spinal cord being sometimes cut with the knife; Jewish slaughterers, for reasons of ritual, first throw the animal and then cut its throat in every case. The modern method, which is at present used for about one million animals yearly in Great Britain, consists in preliminary stunning with a specially designed pistol, after which the animal must be immediately bled.

From the humane point of view the superiority of the pistol over the poll-axe has been placed beyond serious question by the experiments conducted on behalf of the Corporation of London by the Medical Officer of Health (Dr. W. J. Howarth), the Superintendent of the Metropolitan Cattle Market (Mr. J. R. Hayhurst), and the Veterinary Surgeon at the Central Meat Market (Lieut.-Col. T. Dunlop Young). These officers found, in a number of trials with careful and experienced slaughtermen, that it took on the average 2·49 blows with the poll-axe to stun a bull, 1·23 blows to stun a steer, 1·27 to stun a cow, and 1·55 to stun a large sow or boar. With careless or less experienced slaughtermen the results would have been still less favourable. On the other hand, with a particular captive-bolt pistol, 542 bovines were stunned with 543 shots and 712 swine were stunned with 715 shots. Starling and Foster found that when the throat is cut with exceptional skill (in the Jewish method) the duration of consciousness, as tested by corneal reflex and by purposiveness of movement, varies from 5 to 40 seconds, with an average in the neighbourhood of 20 seconds. The qualitative superiority of the pistol over the knife, from the humane point of view, may be regarded as established, though there is some difference of opinion as to the quantitative aspect of the matter. However, Sir Arthur Mayo-Robson has described an important post-mortem test which does not appear to have been applied in the investigations under consideration: it consists in examining the meninges. Dr. Pfister, Director of the Zurich Abattoir, has found that when animals have been stunned before killing their meninges are normal, whereas in animals killed without stunning, as many millions are in Great Britain, the meninges are intensely congested, a fact which proves that suffering has occurred. Finally, the use of the knife has to be learned by practising upon living animals.

The captive-bolt pistol does not involve danger to the slaughterman or to bystanders, and its use calls for only such reasonable care as may fairly be demanded from a tradesman. The meat traders' federation collected for the London County Council inquiry 15 examples of alleged accidents occurring with 'humane killers' between 1913 and 1920, but of these 5 turned out to be cases of suicide and 4 to be otherwise irrelevant. Of 5 genuine and 1 suspectedly genuine accidents, 5 occurred with pistols of the free-bullet as distinct from the captive-bolt type, and in the remaining case the type of pistol was not specified.

There are, however, other considerations which cannot be quite so easily dismissed. The most difficult of these is the allegation that pigs do not bleed so freely when shot as when killed by the old-fashioned methods, and that shot pigs are therefore less valuable for the manufacture of export bacon. It is also alleged that the flesh of shot pigs is more liable to be disfigured by 'blood splash.' The Corporation of London's research negatives the second of these allegations but leaves the first undecided: not only scientific authorities but also those engaged in the trade are divided on the subject, and further trials are called for. Doubtless a great deal depends on the precautions taken to promote bleeding immediately after shooting. In any case, it should be borne in mind that in large factories the pigs, when hoisted, are attached to a travelling conveyer, and owing to the weight of the animal the pressure of the chain on the leg will cause suffering, apart from the use of the knife.

In the case of sheep the difficulty is somewhat different. If a sheep be lifted on to the crutch and then shot, its struggles are said to make manipulation of the pistol more difficult than that of the knife. If, on the other hand, it be shot on the ground, the labour of lifting it on to the crutch afterwards is increased. Thus a 7-handed gang slaughtering 100 sheep a day might need an extra hand, whose wages would possibly amount to 12*s.* 6*d.* a day. The increased cost of production would therefore be about 1½*d.* per sheep, or 0·025 pence per lb. of mutton. Such a small expense should not be allowed to obstruct the ing of what is clearly just and right; Switzerland, Holland, Germany, Sweden, and Denmark have set an example which Great Britain could follow.

In the Jewish method of slaughter, which is governed by a traditional ritual, the animal is first cast, after which its throat is cut with exceptional skill and elaborate precautions. From the humane point of view throat-cutting is not so satisfactory as stunning, but the most serious objection to this method is the preliminary casting, which in the opinion of Starling and Foster involves definite cruelty, sometimes of a serious character. The Jews are by nature and tradition a humane race, and it should not be impossible for their experts to devise some modification of the procedure which will satisfy all the requirements of the situation. Indeed, so recently as Mar. 17 an important test was held at Brixton of a new apparatus designed by Mr. H. Weinberg to obviate the cruelty involved in casting. It is understood that a number of veterinary surgeons who were present were satisfied that a great advance has been made, and it is to be hoped that mercenary interests will not prevent Mr. Weinberg's apparatus from receiving a more extensive trial.

The compulsory training and licensing of slaughtermen is a pressing requirement, for while most slaughtermen are fully trained before they use the poll-axe, there is no adequate provision for the enforcement of this elementary precaution against the infliction of unnecessary suffering. But perhaps the most serious defect of our slaughtering system, both on humane and on hygienic grounds, is the lack of adequate control and inspection of slaughterhouses. In the more advanced of the Continental countries, private slaughterhouses have been extensively replaced by public abattoirs, but unfortunately in Great Britain private slaughterhouses still exist, and their licences have a capital value which opposes a strong vested interest to the movement for reform. The financial cost of doing what is right in this case is by no means an inconsiderable one. Obviously, however, the element of fear can be much diminished in a properly designed public abattoir, which also facilitates supervision for humane and hygienic ends. Hence public abattoirs alone are tolerable in towns, while in country districts a rigorous system of inspection and control by public officers is called for. The hardship which would be inflicted on the "slink" trade in meat from tuberculous animals could be softened by a good system of insurance.

It will be seen that while a very substantial body of facts may be regarded as established in connexion with humane slaughtering, there are other facts—and particularly as regards the effect on the quality of bacon and the psychological element in the suffering of the animals—which call for authoritative investigation. It is essential that the experimental work involved should be carried out by disinterested scientific men, adequately familiar with the canons of scientific method. However, apart from prejudice and conservatism and the professional pride taken by slaughtermen in a highly skilled trade, which they have learned by long apprenticeship, the opposition to reform is based on mercenary considerations. Even if the shot pig should prove to be somewhat less valuable for export bacon than the pig which has been more painfully killed, the question will arise whether the economic motive should prevail over the ethical.

The Ministry of Health proposes two alternative by-laws for adoption by local authorities, but does not enforce their acceptance. By-law 9a requires that all slaughterers except Jews shall stun the animal before killing it, except in the case of sheep. By-law 9b is similar, but it applies also to sheep and specifies the use of a mechanically operated instrument—that is, in practice, a pistol. Out of some 2000 local authorities only 226 (including t London County Council) have hitherto adopted stricter by-law, though the number is growin response to propaganda by the Royal Society the Prevention of Cruelty to Animals, the Humane Slaughter of Animals Association, and other humanitarian bodies. The adoption of the by-law may put a district at an economic disadvantage in its competition with neighbouring districts for the patronage of butchers, many of whom are prejudiced against the pistol. The Sanitary Committee of the Corporation of London has therefore passed a resolution to the effect that the time is now opportune for the issue of definite regulations which should be of general application throughout Great Britain, and that "in order to secure uniformity such regulations should be issued as compulsory regulations by the Ministry of Health." Presumably the Government will hesitate to take the necessary action until it feels itself supported by a well-informed public opinion, but the subject is an unpleasant one, and the public naturally prefers to know as little of it as possible. In the face of this situation, no apology is needed for having brought it to the attention of scientific men, who are *ex hypothesi* opposed to obscurantism.

C. W. Hume.

Science and Psychic Behaviour.

The British Journal of Psychical Research. Vol. I. No. 5. Jan.-Feb. (London: National Laboratory of Psychical Research, 1927.) 1*s*.

THE accusation is frequently levelled at scientific workers that they will give no thought or credence to the very real phenomena of the supernormal, and that this attitude of aloofness sits ill on those who profess the true scientific spirit. That there is truth in the charge can scarcely be gainsaid. When Sir Oliver Lodge pronounces on a modern development or even a modern speculation of molecular physics, the auditorium is filled with craning necks and assenting minds, but let him turn to the subject of materialisations or the after-life, the scientific necks are relaxed and the minds closed. It is worth while inquiring why this conspiracy of hostile silence is maintained.

It is a truism that trustworthy scientific work can be accomplished only by trained minds after elaborate preparation for a line of attack based on a close study of the problem. For in all circumstances the question at stake is the question of what is and what is not admissible evidence. The scientific process is the method of collecting and assembling that evidence, and no deduction will [illegible]nd that allows of possible ambiguity or for which [illegible] evidence is not both necessary and sufficient. [illegible]n legal standards are not permissible. The [illegible]al conclusion cannot be based on circumstantial evidence, nor does one give an electron the benefit of the doubt. The logic of the law court is not necessarily the logic of the laboratory.

In these circumstances it is permissible to doubt that any individual, no matter how well intentioned, could sail into a notoriously difficult region of inquiry and produce almost immediately astounding results of full evidential value. Even were the individual a trained scientific investigator, there is a natural hesitancy in acceptance, for independent verification by other workers is a necessary and legitimate demand. The difficulty is accentuated when the scientist who undertakes or is present at the inquiry is constrained to work under conditions and limitations the full implications of which cannot be precisely appreciated. The phenomenon, he may be told, will take place only in darkness, or in dull red light, or in the presence of a particular individual or a group of individuals, or when a gramophone plays in the subdued light of a vacuum tube discharge, and so on. If, moreover, the events described as occurring, when accepted, would involve a complete reconsideration of the structure of mechanical processes, reluctance [illegible] admit that the evidence is above criticism is naturally intensified.

These are the difficulties one encounters with most of the material in the publication before us. If the merest fraction of the evidence adduced in this small volume were to be admitted it would cause a revolution in scientific thought. In a lecture delivered at the National Laboratory of Psychical Research, Countess Wassilko-Serecki describes the history—one is almost tempted to write the hysteria—and phenomenon of Eleonore Zügun, a Rumanian peasant girl. In the presence of this girl inanimate objects become endowed with a will of their own, bricks fly about, dishes dash themselves to pieces, a stone jumps out of the river, is replaced and jumps out again, scratches and bites appear on her arm, cups are snatched from her hand by invisible powers, and so on. A great deal of the evidence for this is not direct but produced by the Countess from depositions of individuals abroad. Dr. R. J. Tillyard contributes a record of two séances conducted by a medium in Boston, Mass. Here darkness appears to be essential, and the medium goes into a trance. This is verified at intervals by red light. It would be interesting to have details of the verification of this trance condition conducted in such difficult circumstances, but they are not provided. A gramophone plays a negro melody and a voice—immediately referred to as 'Walter's' voice—talks "freely and wittily" apparently from inside a cabinet. The humour does not, however, appear to be very deep. A flower basket—rendered luminous—moves about high up in the room, rocked by 'Walter,' we are told, but no evidence is adduced about 'Walter' beyond the voice, or as to whether the basket was actually rocked by him.

Much could be said about this kind of science, but restraint is desirable. Numerous questions naturally suggest themselves. If a brick can fling itself through a window, what reliance can be placed on the prediction of the total eclipse in June? What reliance can be placed on the performance of *any* machine? Alternatively, if, as experience shows, full reliance can be placed on a multitude of such predictions, what reliance can be placed on the evidence about the brick? Scepticism becomes charity indeed. There is here a frank conflict of evidence [illegible] until it is resolved the scientist's natural inclin[illegible]s to turn back to the restful haven of verified knowledge. If there are inconsistencies in his own field, if for the moment he cannot reconcile solar mechanics with the mechanics of the electron, his past experience has at least taught him that with patience these troubles will be smoothed. Consistency of behaviour of his material, however, is implicit in his method of approach. Such an assumption may possibly prove to be ill-founded, and the self-propulsion of the brick through the window, referred to above, may ultimately prove to be the actual disturber of his mental peace. But his *malaise* in the presence of such a phenomenon—if true—goes deeper than this. "If the material with which I have to deal," he says, "is not consistent in its behaviour, how can I study the question at all?"

It seems to be inevitable in experiments in this field of inquiry—if they can be called experiments—that a great deal must depend on the good faith of the medium. There is always the lurking suspicion that, consciously or unconsciously, the observers are being deluded—a factor utterly foreign to any class of physical experiment. This suspicion is traceable not so much to the fact that, in the past, trickery has been exposed in the performances of such individuals, as to the fact that results are claimed of a nature antagonistic to the tacit philosophy of the physicist. To meet this difficulty, one of the first tests that ought to be performed should be to determine the precise conditions under which a medium can be dispensed with. Quite obviously, the smaller the number of persons actually essential to an experiment, the greater the confidence in the result. Is it not possible for the National Laboratory of Psychical Research to produce the details of a single and convincing experiment that could be performed by any competent scientific worker in his own laboratory, as simple, say, as measuring the period of a pendulum? If 'levitations' are as frequent as they are claimed, this should not be impossible. The writer has frequently tried such experiments alone, but always in vain. What are the conditions that will ensure success? Surely, after so many years' experimentation by devotees of the cult, including many eminent men, this must be known very accurately. All the tests described in the publication under review are so complex that instead of carrying conviction they arouse suspicion. It is the simple test that is required.

There is, however, another—and possibly more important—factor that repels the scientist: it is the implications and assumptions inherent in the descriptions of these uncanny doings. If a voice is heard speaking from a box, is it necessary to assume it has an owner, 'Walter'? In a court of law it might be a legitimate assumption to make, and it might in conceivable circumstances be sufficient to hang a man, but in the description of a scientific experiment, why imply the existence of an 'owner' to the voice and by identifying it with 'Walter'? Even assuming the accuracy of the phenomenon, which in the circumstances one would be far from doing, there are numerous possible working hypotheses of a more normal type than that of 'spirits.' When Sir Richard Paget makes his hands speak, one does not assume that the voice belongs to a spirit, even if it does call itself 'Walter.' Men of science have learnt that words are treacherous things, that false ideas of an ignorant past are dragged in at each turn, so they have learned to talk in symbols, with a clear-cut (1, 1) correspondence between idea and symbol. But the language of supernormal behaviour—and the very phrase itself is dangerous—is not yet sufficiently divorced from mystery and superstition, not yet sufficiently definite and precise, to ensure that the pet theories and vague beliefs of its devotees are not foisted on the unwary inquirer as he receives his description of the phenomena.

If the National Laboratory of Psychical Research can produce a simple laboratory experiment, capable of being performed by a careful and trained scientist under conditions that he himself can guarantee and control, it would go further towards producing the revolution in thought which the Council so earnestly desires than volumes of 'evidence' of the type given in the present issue of its Journal.

H. Levy.

Dynamics and Ballistics.

(1) *Lezioni di meccanica razionale.* Per Tullio Levi-Civitá e Ugo Amaldi. Volume secondo: *Dinamica dei sistemi con un numero finito di gradi di libertà.* Parte prima. Pp. x+527. (Bologna: Nicola Zanichelli, 1926.) 65 lire.

(2) *New Methods in Exterior Ballistics.* By Prof. Forest Ray Moulton. Pp. vi+258. (Chicago: University of Chicago Press; London: Cambridge University Press, 1926.) 20*s.* net.

(1) THE monumental treatise which Profs. Levi-Cività and Amaldi are engaged in writing on rational mechanics (to use the comprehensive title established on the Continent) is divided into three volumes, which deal respectively with kinematics and statics, dynamics of systems possessing a finite number of degrees of freedom, and dynamics of continuous systems. The second volume is divided into two parts, to the second of

which are reserved the general questions properly belonging to rigid dynamics and the subjects of canonical equations of motion and the principle of Hamilton and Jacobi.

The plan of the first part of the second volume is as follows: The first two chapters discuss the motion of a particle constrained to move on a given curve and on a given surface. The third chapter deals with problems of gravitational attraction. General theorems on momentum, energy, and work are treated in Chapter iv. D'Alembert's principle and Lagrange's equations occupy Chapter v., and the volume closes with a chapter on stability of motion and small oscillations.

Chapter iii., which is mainly concerned with celestial mechanics, contains interesting applications to planetary orbits according to Einstein's law of gravitation and to electronic orbits according to Bohr's atomic theory. The motion of electrons in an electromagnetic field also furnishes interesting examples. It is, indeed, a refreshing change to discover so little space devoted to questions better fitted to exercise a student in integration than in dynamical principles.

Into the time-worn problems to which so large a proportion of any work on dynamics must be consecrated it would be difficult to introduce much originality of treatment. Yet throughout this work, Profs. Levi-Civita and Amaldi have succeeded in revivifying these 'dry bones' by a continual slight novelty, most stimulating to the reader. The work is planned on generous and comprehensive lines and covers ground scarcely touched in any similar treatise. It even contains a fair number of exercises for the student.

(2) Prof. Moulton's short account of some methods of external ballistics discusses the three main problems of the effects of air resistance, rotation of the projectile, and minor factors such as winds, on the projectory. The effect of air resistance is studied by the methods of finite differences, extensively used by Bashforth in England during the last century. The effect of abnormal air densities, variations in gravity, winds, etc., is studied by the method of perturbations, so widely used in astronomy. The effect of rotation is discussed by means of the classical equations of Euler. The book contains no reference to the pioneer work of Bashforth or to the work of Siacci. Few of the methods given appear to be new, and a remarkable new method due to Whitehead ("Graphical Solution from High-Angle Fire," *Proc. Roy. Soc.*, 1918) is not mentioned. It seems that the title of the book is scarcely an accurate description of its contents. Considerable interest therefore attaches to an ingenuous admission in the introduction. "In view of the complete independence of the present developments from those that have gone before, no attempt has been made to treat the question historically, nor even to connect these results with those of earlier writers." This is an explanation, if not an excuse.

Animal Nutrition in Sweden and Denmark.

Fütterung der Haustiere: ihre theoretischen Grundlagen und ihre wirtschaftliche Durchführung. Von Prof. Nils Hansson. Übersetzt von Franz von Meissner; überarbeitet und mit einem Vorwort versehen von Prof. Dr. Georg Wiegner. Pp. xii + 230. (Dresden und Leipzig: Theodor Steinkopff, 1926.) 8 gold marks.

THE science of animal nutrition is concerned with the principles underlying the economical transformation of the produce of the soil into articles of human diet like meat and milk. The elucidation of these principles depends on a knowledge of two sets of factors: first, the nutritive requirements of the different classes of farm stock for the purposes of maintenance and of production (*e.g.* growth, fattening, and milk production); and secondly, the capacity of the various feeding stuffs for supplying these requirements.

It is instructive to note how these problems have been attacked in Germany and the United States on one hand, and in the Scandinavian countries on the other. In Germany the well-known investigations conducted by Kellner on fattening oxen in the respiration calorimeter have led to the formulation of a system of starch values, in which the productive or, more strictly speaking, the fattening value of a feeding stuff is defined in terms of pounds of starch. Kellner's system has been widely adopted in Britain, where, within limits, it has given useful results, though criticism of the method at the present time is not lacking. Armsby in the United States, also working with fattening oxen in a respiration calorimeter, has evolved a system of net energy values in which the productive value of a feeding stuff is stated in terms of therms of energy.

In northern Europe, however, where dairy cows, and not fattening oxen, have been mainly employed in feeding investigations, it has been the custom to take milk production as a measure of the productive value of a feeding stuff. Experiments on these lines were first started by Fjord at Copenhagen so long ago as 1885, and since 1898 these have been continued and expanded in a series of fundamental researches carried out by Nils Hansson at Stockholm. From the results of these feeding trials came the conception and development of the Scandinavian food unit system, which is now accepted as the basis of feeding in Sweden, Denmark, Norway, Finland, Poland, and other countries. This system, based on Hansson's data, has undoubtedly, in its application to feeding practice, achieved a larger measure of success in northern Europe than has any other system in any other country, and to its adoption must be attributed in no small degree the vast growth of the butter export trade of Denmark and the enormous increase in milk production in Sweden and other northern lands.

Prof. Hansson's main work, "Handbok i Utfodringslära," was published in three parts and contained a detailed account of the development and application of the food unit system. The present volume appeared in 1922 under the title of "Husdjurens Utfodring" and brought together all the essential features of the "Handbook" in carefully condensed form. Unfortunately, not many English workers are able to read Swedish with any degree of ease, and this fact probably explains the somewhat tardy recognition of Hansson's ideas in Britain. The translation of "Husdjurens Utfodring" into German is the direct outcome of a widespread desire among German nutritional scientific workers to know more about a feeding system which has proved so successful in other countries.

The treatment of the subject is characterised by the simplicity and logical clearness for which Hansson's publications are justly celebrated. The first section opens with an account of the composition and digestibility of feeding stuffs, the concluding chapter of this section dealing with the different methods of assessing productive values. The English reader will be particularly interested in the comparative account of the Hansson food unit, the Kellner starch value, and the Armsby net energy value. In the second section the nutritive properties of the individual feeding stuffs are dealt with, while the third and concluding section is devoted to a thorough consideration of the scientific principles underlying the nutrition of calves and other young animals, of dairy cows and fattening oxen, of sheep, pigs, goats, and horses. The tables at the end of the book constitute a praiseworthy feature. Table I. gives the average composition and digestibility of a very large number of feeding stuffs, together with their productive values in terms of food units, starch values, and milk-producing values. In Table II. the nutritive requirements of all classes of farm stock are recorded in great detail.

It is to be hoped that the translation of Hansson's treatise into English will not long be delayed. Affording as it does a fresh and hopeful outlook on the problems of the economical feeding of farm animals, especially of dairy cattle, it should prove a worthy companion volume to the well-known treatises of Kellner and Armsby and the more recently published text-book of the Cambridge worker, Prof. T. B. Wood. It should be read with interest and profit not only by the investigator in this domain of science, but also by all stock-breeders who are desirous of rearing their animals in accordance with accepted scientific principles.

H. E. WOODMAN.

Our Bookshelf.

Delusion and Belief. By Prof. Charles Macfie Campbell. Pp. v+79. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1926.) 6*s.* 6*d.* net.

THIS is an interesting study of the relation of the various beliefs which men have held at different times to their conduct of life. The method of treatment begins with the biological study of belief, pointing out how, although we cannot tamper experimentally with our fellows in regard to the main issues of human life, yet Nature does not shrink from exposing men to the most searching tests.

Various beliefs are discussed which are concerned with topics of high emotional value, such as bereavement, unsatisfied love, and ungratified ambition, and it is pointed out and examples are given of the way in which the attitudes and beliefs of the individual have a strongly subjective note. In the latter part of the book, man's general belief concerning the mechanism of Nature and the order of the cosmos is discussed. Here again the personal viewpoint is noted. The question of the mental health of the individual and the group depends largely on the underlying scheme of values.

The book concludes with a discussion of what the author terms inferior beliefs about health, such as Christian science. Although admitting the personal comfort in some cases, he maintains that any increased efficiency is largely due to adopting the healthy attitude that, even when there is some physical ailment, it is often better to ignore it and to go on playing the game of life. He also points to the danger of inferior beliefs about social problems, such as that of the optimist who talks of universal peace and often denies the existence of harsh realities and hatreds. The belief in the spiritual order of the universe is an important driving force, but it must also be associated with the workaday world. Although tolerant of various beliefs, Prof. Campbell's conclusion is that instead of discovering something absolute in the realm of belief, one finds that beliefs are the tools of life rather than rare intellectual products to be cherished carefully for themselves. H. D. A.

Tribal Dancing and Social Development. By W. D. Hambly. Pp. 296 + 26 plates. (London: H. F. and G. Witherby, 1926.) 21*s.* net.

Mr. Hambly has surveyed dancing and music as a communal activity and expression of emotion literally from the cradle to the grave, for he begins with the celebration of a birth and ends with the dance which follows death—often long after death, like the dance in the Nicobarese ceremony of disinterring the dead and collecting their bones. He does not concern himself with the individual or merely exhibition dancing as such, although in some of the Eastern dances it would be difficult to draw the line—for example, the whipping dance as a test of endurance as performed in the Sudan which he describes—and it would be easier to discriminate even in this case if it were possible to trace whether or not there were any possible connexion with the whipping ceremony sacred to Artemis, which was once celebrated at Sparta.

Important as it may be to consider dancing as a tribal or group activity, as an expression of an emotion, in ultimate analysis, it must be individual; and the same applies to music. In both cases, fundamentally, the appeal is to the rhythmic sense. Even in music, melody appears to be secondary. Those who have heard real savage music know what a wild appeal to the emotions can be made by the mere rhythmic beating of a drum; while the effect of modern dance music, undeniably, however much it may be disliked, lies in its beat and not in its tune. An analysis of the dance, whether individual or communal, as an effect of rhythmic appeal, has yet to be written.

Mr. Hambly's treatment is on more objective lines. His survey of the facts is a useful study of the geographical distribution and character of the dance as an element in ceremonial, which will be invaluable to the student and at the same time serve to bring home to those whose interest is least specialised, its importance as a social factor which, if not approached sympathetically in administration, might give rise to infinite difficulty.

The British Journal Photographic Almanac and Photographer's Daily Companion, with which is incorporated The Year Book of Photography and Amateurs' Guide and The Photographic Annual, 1927. Edited by George E. Brown. Pp. 820 + 31 plates. (London: Henry Greenwood and Co., Ltd., 1927.) Paper, 2*s.* net; cloth, 3*s.* net.

This is no longer an almanac, except in name, for that particular feature of the annual has been omitted since a year or two ago, presumably because it was not appreciated. We appreciated it and often turned to it After four articles dealing with the use of reflex cameras, arranging snapshots, developing and printing amateurs' films, and the use of 'chlorobrom' papers, follows the valuable "Epitome of Progress," which is a concise and classified history of photography for last year. It includes a very brief summing up of the most striking advances, the events of the year, besides trade and legal items. The largest section of the epitome concerns apparatus, equipment, and processes, and consists of abstracts of the accounts of these that appeared during the year, with all necessary formulæ and many illustrations. After the obituary, 65 pages of formulæ and instructions for the current photographic operations, and 40 pages of tables, comes a section of miscellaneous information. This last includes an excellent "History in Brief" of photographic and photomechanical processes, and various directories. With the text are 30 photogravure reproductions of photographs by some of the most noted workers. The annual fully maintains the unique position that it has earned for itself during its sixty-seven years of issue.

Three Lectures on Atomic Physics. By Prof. Arnold Sommerfeld. Translated by Dr. Henry L. Brose. Pp. iv + 70. (London: Methuen and Co., Ltd., 1926.) 2*s.* 6*d.* net.

It is encouraging to find that these important lectures by one of the most prominent authorities on spectroscopy, delivered under the auspices of the University of London, are now accessible to all in English. They deal with the spectra of hydrogen and helium, and then proceed to the study of complex spectra such as manganese, iron, nickel, and palladium in the light of Pauli's "Principle of Uniqueness." The third lecture gives some much-needed information concerning the structure of crystals, from the point of view of the quantum theory.

The translation is carefully done, but errs on the side of literalness. The translation of *Grundzustand* as 'ground state' is scarcely English, while *abgeschlossen* as applied to systems of elements is 'self-contained' rather than 'completed,' and 'quantize' is rather more exotic than 'quantify' would be.

New Conceptions in Colloidal Chemistry. By Prof. Herbert Freundlich. Pp. vii + 147. (London: Methuen and Co., Ltd., 1926.) 6*s.* net.

This volume contains eight lectures delivered by the author in America in 1925. They deal in a masterly manner with the progress made along certain lines in colloid chemistry during the last few years, and indicate that such matters as adsorption, electrolyte coagulation, and the electrical and optical properties of colloidal systems are not so simple as they were once thought to be. The ample bibliographies, although impartial, show how fundamental is the work of Prof. Freundlich himself, who is to be congratulated on the rare gift of making his discoveries intelligible in two languages, for a German version of the book has already appeared. Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Constitution of Mercury Derived from Coal Tar.

IT will doubtless be a surprise to many readers of NATURE, as it was to me, to hear that the element mercury is obtained in the distillation of coal tar. This fact was recently brought to my notice by Mr. W. Kirby, of the South Metropolitan Gas Co., who kindly provided me with a sample for examination of its isotopic constitution. He informs me that the mercury appears in the lightest of the fractions distilled and occurs to the extent of about one part in seven millions of undistilled tar. Its accumulation in any reasonable quantity will, therefore, take place only in a plant arranged for continuous fractionation.

It was my first intention to compare its density with that of ordinary mercury, and if any appreciable difference was detected to submit it to analysis by the mass-spectrograph, but a favourable opportunity having occurred, I have been able to perform the latter operation under advantageous conditions. The discharge bulb was washed with carbon dioxide until all trace of the spectrum of mercury had disappeared. A portion of the sample was then introduced. This operation was more troublesome than I expected; but ultimately the bulb was flooded with the vapour and a number of mass-spectra were obtained, while the mercury spectrum was predominant in the discharge. On these the groups of isotopic lines were absolutely indistinguishable, both in position and intensity relations, from those of ordinary mercury described in NATURE, Aug. 8, 1925.

Cambridge, Mar. 10.

The Passage of α-Rays and β-Rays through Matter.

THE loss of energy suffered by a fast-moving electrified particle passing through matter, and the ionisation produced by the moving particle, are phenomena which have, so far, not received accurate quantitative explanation. There are two main theories of the stopping-power due respectively to Bohr (*Phil. Mag.*, 25, 10; 1913; and 30, 581; 1915) and Henderson (*Phil. Mag.*, 44, 680; 1922). The theory of the primary ionisation due to a fast-moving particle is as it was left by Thomson in 1912 (*Phil. Mag.*, 23, 449). In all these theories, classical mechanics is used to calculate the possible energy transfers during encounters between the moving particle and the atomic electrons, and Fowler (*Camb. Phil. Soc.*, 21, 521; 1923) has suggested that the discrepancy which exists between theory and experiment may be due to the inaccuracy of classical mechanics in this field. *Whether this is so or not, it may be of interest that a fair proportion of the discrepancy between classical calculations and experimental results disappears when the motion of the atomic electrons is allowed for.* The effect of this motion may be considerable, though the velocity of the electron be small compared with that of the moving electrified particle.

The momentum imparted to an electron by a fast-moving electrified particle is to a first approximation independent of the initial motion of the electron, and it is the same as that communicated to an initially stationary electron provided the shortest distance between the undisturbed paths of the electron and moving particle is the same in both cases. If ϵ represent the kinetic energy of the electron in its orbit and Q_0 the energy given to an initially stationary electron, then, adding momenta, we find that the energy, Q, acquired by an electron is given by

$$Q = Q_0 + 2\sqrt{Q_0 \epsilon} \cos \phi, \quad . \quad . \quad . \quad (1)$$

where ϕ is a random angle. It would appear that as the value of Q averaged for *all* ϕ is Q_0, it is unnecessary to take the second term on the right-hand side into account. However, in Henderson's theory of the stopping-power and Thomson's theory of ionisation, it is not legitimate to average for all ϕ, only those values of ϕ for which Q is greater than a certain minimum value being concerned. (In Bohr's theory there is no such minimum and it is legitimate to neglect the motion of the atomic electrons.) It follows from (1) and the classical expression for Q_0 that in an element dx of its path the average number, dA, of encounters in which the moving particle gives to the electron energy between Q and $Q + dQ$ is given by

$$dA = \frac{2\pi N' E^2 e^2}{mv^2} \frac{dQ}{Q^2}\left(1 + \frac{4}{3}\frac{\epsilon}{Q}\right)dx, \quad . \quad . \quad (2)$$

usual notation being used. This expression is greater by the factor $1 + \frac{4}{3}\frac{\epsilon}{Q}$ than the expression for stationary electrons. By integration we find that the primary ionisation is given by

$$I = I_P = \frac{2\pi N E^2 e^2}{mv^2} \sum_{s=1}^{n} \frac{1}{V_s}\left(1 + \frac{2}{3}\frac{\bar{\epsilon}_s}{V_s}\right) = k \sum_{1}^{n} \frac{1 + \frac{2}{3}\frac{\bar{\epsilon}_s}{V_s}}{V_s}, \quad (3)$$

N being the number of molecules per unit volume, n the number of electrons per molecule, V_s the binding energy of the sth electron, and $\bar{\epsilon}_s$ its average kinetic energy. (Quantities of the order of u^2/v^2 where u is the initial velocity of the electron and v the velocity of the moving particle are neglected, and this represents the accuracy of the results.) According to Thomson's theory

$$I = I_T = k \sum_{1}^{n} \frac{1}{V_s}. \quad . \quad . \quad . \quad (4)$$

The difference lies in the extra term $\frac{2}{3}\frac{\epsilon}{V}$ in the numerator of (3). ϵ/V is generally equal to or greater than unity, so that the new value is at least about 70 per cent. greater than the old value. C. T. R. Wilson (*Proc. Roy. Soc.*, 104, 192; 1923) found that the primary ionisation produced by β-rays in air was about double Thomson's theoretical value. The value given by (3) is thus nearer the experimental value than the value given by (4), although the uncertainty of atomic data prevents a final comparison. The data for hydrogen is more certain, and certain experimental results obtained by the writer for this case are in satisfactory agreement with the new result. The new theoretical value in fact agrees to within about 5 per cent. with the observed value of the primary ionisation in hydrogen, whilst the theoretical value according to Thomson's theory represents little more than half the observed ionisation.

If R represents the first resonance potential of an electron, then Fowler (*loc. cit.*) has shown that the stopping-power according to Henderson's theory is approximately given by

$$S_H = \frac{2\pi N E^2 e^2}{mv^2} \sum_{s=1}^{n} \log Q_m/R_s \quad . \quad . \quad (5)$$

Q_m being the energy given to a stationary electron in an end-on collision. According to the present calculations, in which the motion of the electron is allowed for, the stopping-power is given by

$$S_P = \frac{2\pi N E^2 e^2}{mv^2} \sum_{s=1}^{n} \{\log Q_m/R_s + 4\bar{\epsilon}_s/3R_s\}, \qquad (6)$$

the correction being equivalent to decreasing R by a factor of $e^{4\bar{\epsilon}/3R}$. Fowler has shown for α-rays and Wilson for β-rays that the expression (5) is appreciably less than the observed stopping-powers. The curves in the accompanying figure show to what extent the corrected formula agrees with observations in the case of oxygen.

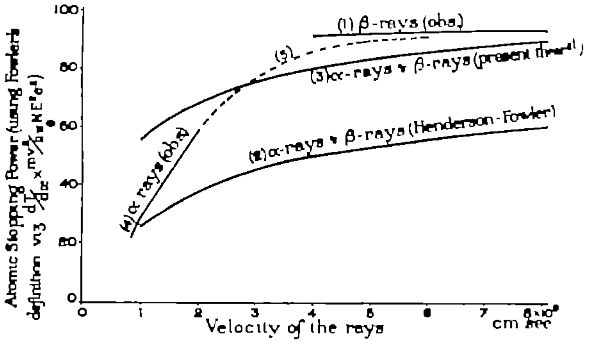

Fig. 1.

Curve (1) represents observed values of the atomic stopping-power for β-rays in oxygen, obtained recently by J. M. Nuttall and the writer (*Phil. Mag.*, **2**, 1109; 1926): curve (2) stopping-powers calculated by the Henderson-Fowler formula: curve (3) stopping-powers calculated by the formula proposed here. In curve (4) the observed stopping-powers for α-rays are plotted. To avoid having too many curves the value of Q_m for β-rays is taken equal to the value for α-rays having the same velocity, and a corresponding reduction of the observed values for β-rays is made (involving a change of about 15 per cent.). After making this reduction the theoretical curves for α-rays and for β-rays coincide.

Although the data used in calculating S_P and S_F is rather uncertain, there can be no doubt that the corrected formula (5) shows a better agreement with observation than formula (4).

It is to be expected that the theoretical formulæ for stopping-power should fail at small velocities because it has been assumed that the 'times of collision' for all 'effective' collisions are small compared with the period of revolution of the electron in its orbit. If this condition is not satisfied, there is an *extra restriction* imposed upon the transfer of energy to the atomic electrons, and the stopping-power represented by curve (3) is consequently too high at the lower velocities. This effect probably accounts for the fact that the observed α-ray curve is below curve (3), and also for the comparatively rapid variation of the stopping-power for α-rays with velocity. The relative effect of this new restriction would be expected to be somewhat greater for α-rays than for β-rays with the same velocity. On this view the observed α-ray curve at higher velocities should approach asymptotically the observed β-ray curve, as is indicated by the broken curve (5). It would be interesting to know the stopping-power for α-rays faster than those from radium-*C* to see if this is the case.

E. J. Williams.

Manchester, Feb. 24.

Coup-de-Poing.

Of that famous palæolithic implement which the French call a 'coup-de-poing,' the function is still unknown and disputed; it was once called a 'celt,' and is still regarded by some experts as the head of a once hafted ax; others, like the late M. Commont, have argued that it was used as a scraper, and still others maintain that it is an ax without a helve.

In order not to do violence to the feelings of some of our friends by forcing upon them a name which expresses a view from which they differ, I have suggested, as non-committal and non-combative, the use of a proper name; thus following the example of physicists, who speak of a watt or a volt.

The name I proposed is that of the famous Frenchman, who did such splendid service with the 'coup-de-poing' in his fight over the antiquity of man. I allude, of course, to Jacques Boucher de Crèvecœur de Perthes. From this full title I chose his family name of Boucher. This is not a Christian name, as my friend Mr. Balfour supposes, and my authority for saying this is our distinguished colleague, the Foch professor of French.

A second objection raised by Mr. Balfour in his interesting review (Nature, Feb. 12, p. 226), is that Mr. Neville Jones has misapplied the name. I do not think he has, but this is nothing to the point, for he distinctly asserts that he uses the word 'boucher' as equivalent to the French 'coup-de-poing.'

Admiring as I do the consistent courtesy of Mr. Balfour, which is not confined to his friends, I feel sure he will not wish to introduce into our nomenclature a term like 'hand-ax,' which is eminently controversial and has not even the advantage of elegance. Who would speak of a knife-blade without a handle as a 'hand-knife'?

W. J. Sollas.

University College, Oxford,
Feb. 23.

I am glad that Prof. Sollas has commented upon a remark of mine in my review of Mr. Neville Jones's book, as it gives me an opportunity of correcting an error of my own. When I referred to Prof. Sollas's "Ancient Hunters," in order to ascertain his original application of the term *boucher*, I read the passage (p. 112) as indicating that he wished to apply it to implements "made by striking off with a single blow a thick flake from a larger block of stone, and dressing the side opposite the surface of fracture by several blows directed more or less parallel to its length." I have again read the passage and realise that his intention was to suggest *boucher* as equivalent to the French *coup-de-poing*. I was misled through not having read the passage on the succeeding page, and I assumed that "it" in the sentence "In English it has no name," referred to the type described as above quoted. My reading of the paragraph was also partly influenced by the author having drawn a decided parallel between the Tasmanian implement-type, to which he had just referred, and the so-called *coup-de-poing* series. I apologise for having misinterpreted his intention.

At the same time, I cannot admit that the Tasmanian type—a typical *flake*-implement—is to be regarded as the "homologue, or rather analogue," of the *coup-de-poing*—an equally typical *core*-implement. The technique employed in making the two types is essentially different, and the resultant edges differ in character and, doubtless, in application. But, even if *boucher* is offered as a term to take the place of *coup-de-poing*, I cavil at its adoption, since it is made to cover such a variety of distinct implement-types, ranging from the Chellean pick-like tools with rounded butts and pointed 'business' ends, to the specialised ovates of the Upper Acheulian series. It is used, in fact, to denote very dissimilar types of tools, the form and presumable function of which have but little in common. It is true that I feel equally dissatisfied with those widely-adopted terms *coup-de-poing*, *faustkeil* and *hand-axe*, all of which, as commonly used, beg a very debateable question; as I venture to doubt whether those early-palæolithic tools which were equipped with a sharp edge all round their contour, were habitually used unhafted (*vide* Sollas, p. 74). I mention this in order to emphasise how badly we are in need of a revised and reasonably descriptive terminology in prehistoric archæology. My chief reason for protesting against the adoption of the term *boucher* is its vagueness. It is used to embrace such a wide range of distinctive types that it really ceases to have a descriptive value, and is liable to cause confusion.

As to the name itself, I have been fully aware of the complete name of Jacques Boucher de Crèvecœur de Perthes, and that, strictly speaking, Boucher is not the Christian name; but the abbreviated name-formula, Boucher de Perthes, under which he is universally, and by most people exclusively, known, suggests 'Boucher' as, shall we call it, a *prénom*, and a correlation, albeit erroneous, with such names as John of Gaunt, William of Wykeham, etc., and this opens up a vista of *prénoms* adopted as generic or specific names for types of prehistoric implements. I am far from wishing to discourage homage to that great pioneer, Boucher de Perthes, but I do feel that our great debt to him could be paid more effectively than by requisitioning his name (or, rather, one of his names) for the purpose advocated; since the suggested term *boucher*, by embracing so much, signifies so little.

I greatly regret to find myself even in trivial disagreement with my good friend, Prof. Sollas, and I am merely desirous of expressing an opinion, which, if challenged and debated, may possibly be productive of good, as helping to stimulate the introduction of an adequate terminology in prehistoric archæology.

In regard to the last paragraph in Prof. Sollas's letter, I may say, though I risk his thinking me wholly unregenerate, that I feel no aversion from the use of the term 'hand-axe,' so long as it is confined to blades of axe-like form, the shape of which suggests that they were used unhafted. Nor do I see any objection to applying the term 'hand-knife' to a knife-blade which was not fitted with a handle. Such terms, where appropriately applied, have at least the utilitarian merit of being fairly descriptive, even though they may lack elegance. There is, moreover, precedent in the familiar expressions, 'hand-line,' 'hand-spike,' etc.

HENRY BALFOUR.

Carbon Monoxide Poisoning in the Absence of Hæmoglobin.

MR. J. B. S. HALDANE's interesting letter on the above (NATURE, Mar. 5) reminds me that in 1886 I made experiments on the influence of carbon monoxide, as well as of other gases (carbon dioxide, hydrogen, nitric oxide, nitrous oxide, sulphur dioxide, and hydrogen sulphide), on the vitality of three specific micro-organisms, namely, *Bacillus pyocyaneus*, Finkler's spirillum, and Koch's spirillum of Asiatic cholera. The results were published in the *Proceedings of the Royal Society* (vol. 45, pp. 292-301), but a brief reference to them may not be out of place now, inasmuch as they bear on this matter of the toxicity of gases.

The method of experiment consisted in exposing the several organisms, in the form of gelatin-peptone plate-cultures, to an atmosphere of the particular gas, a corresponding control-plate of the same culture being simultaneously incubated in atmospheric air. The behaviour of the three microbes in question in respect of carbon monoxide may be gathered from the following experimental results:

BACILLUS PYOCYANEUS.

	Air-plates (after 4 days' incubation).	CO-plates (after 7 days' incubation)
Number of colonies developing from 1 c.c. of culture . .	113,978	0

When the above carbon monoxide plates were further incubated in air, 100,821 colonies made their appearance. Thus the carbon monoxide had had practically no *permanent* toxic effect on the bacilli distributed in the culture, which had been exposed for a period of 7 days to the gas.

KOCH'S SPIRILLUM CHOLERÆ ASIATICÆ.

	Air-plates (after 4 days' incubation)	CO-plates (after 7 days' incubation).
Number of colonies developing from 1 c.c of culture .	52,020	19,494

On subsequent further incubation of the carbon monoxide plates in air during 4 days, no increase in the number of colonies took place.

FINKLER'S SPIRILLUM.

	Air-plates (after 3 days' incubation)	CO-plates (after 7 days' incubation)
Number of colonies developing from 1 c c. of culture . .	4574	2

On further incubation of the carbon monoxide plates in air during 4 days, the number of colonies rose to 501.

Thus in both cases, and especially in that of the Finkler spirilla, a large proportion of the individuals had been killed or rendered incapable of multiplication into colonies by exposure to the gas.

It may be of interest to add that plates incubated in atmospheres of nitric oxide, sulphuretted hydrogen, and sulphur dioxide respectively developed no colonies, nor were any developed afterwards on placing the plates in air-chambers. These three micro-organisms are therefore rapidly and permanently poisoned by the gases in question.

Interest, again, attaches to the behaviour of the organisms exposed to nitrous oxide (N_2O). The *B. pyocyaneus* developed no colonies in this gas, but afterwards in air almost as many colonies made their appearance as on the control air-plates. Koch's spirilla, in nitrous oxide, developed nearly one-third of the number of colonies present on the air control-plates, a further but only slight increase taking place on their transference to air. In the case of Finkler's spirilla, in nitrous oxide, the number of colonies was about one-seventh of that on the air-plates, whilst the further colonies which appeared after transference to air brought the total to about one-fifth of the number on the air-control. The effect of nitrous oxide on these three micro-organisms is thus very similar in character to that exerted by carbon monoxide.

An atmosphere of carbon dioxide, again, prevented the development of any colonies on the plate-cultures of all three organisms, and only in the case of *B. pyocyaneus* did any appear on transference to air, and then only to the extent of about one-twelfth of the number present on the control air-plates.

In reviewing the record of these experiments made forty-one years ago, it is obvious how greatly the investigation could be extended in various directions. Thus, for example, it would be particularly interesting to ascertain the deportment of sub-cultures made from the colonies appearing on plates which had been exposed to the toxic gases. By pursuing such experiments through a succession of generations it might be possible to arrive at 'strains' of the organisms endowed with the capacity to resist the inhibiting action of a particular gas. Again, differences in behaviour towards a given toxic gas might be made a means of discriminating between otherwise similar organisms, and thus adding yet one more to the already overwhelming number of tests employed in bacteriological diagnosis.

PERCY F. FRANKLAND.

Loch Awe, Argyll.

The First Public Chemical Laboratory in England.

THE statement (NATURE, Feb. 19, p. 300) that the chemical laboratory opened in 1828 in University College, London, is the oldest public chemical laboratory in Britain can scarcely be accepted without qualification, in view of the fact that the University of Oxford had built a laboratory fitted for chemical studies so early as 1683, and that this remained in use until superseded in 1848 by Dr. Daubeny's new laboratory at Magdalen College.

The use that was made of it was intermittent, and the modern practice of class teaching necessitating the multiplication of sets of apparatus had not been evolved; but still the possibility for a person to witness an experiment, even if he did not wish to make it himself, was there.

In those early days the University of Oxford appears to have done little for chemical studies beyond the initial provision of the laboratory and of "the Alkanor and Great Reverberatory" furnaces, and larger utensils such as the great alembic, barrel and worm, with which it was equipped. Smaller earthen and glass vessels and chemicals appear to have been the private property of the laboratory assistant for the time being, who was permitted to increase a very meagre salary by selling to experimenters chemical preparations "at easie rates" and by taking payment for the performance of experiments himself.

Notwithstanding the non-existence of any special university teachers of chemistry, useful practical instruction had been given in connexion with courses of public lectures in the laboratory at various times during the eighteenth century. The auditors were largely composed of medical students, with a sprinkling of the more intelligent members of the general public, who, like Princess Anne in 1683, entered the laboratory to see experiments "to their great satisfaction"; and some of the more curious-minded of these would doubtless have sought to try the experiments themselves. Dr. John Freind, described as well skilled in practical chemistry, in 1704 began courses of *Prælectiones Chymicæ* in the laboratory, which were partly based on experimental work there, and were printed and reprinted for the next twenty years. Richard Frewin was among those who acted as assistant, and it is not unlikely that there too Dr. John Wall, the inventor of Worcester china, may have learnt his chemical manipulation. George Wingfield has left a written record of the methods of analysis in vogue in 1759, and in 1781 a considerable class of divines is reported to have waded "considerably deep in chemistry." Contemporary notes taken four years later by a pupil of Dr. Martin Wall show the distinctly practical trend of the instruction given, and from 1788 until 1793 the celebrated Dr. Beddoes, later patron to young Humphry Davy, drew to the Ashmolean "the largest classes known in the University since the thirteenth century." It was the period when the work of Sadler, the aeronaut, also helped to popularise chemical experiments in Oxford.

Between 1803 and 1822 the existence of the laboratory made it possible for the first Aldrichian professor of chemistry, Dr. Kidd, to deliver courses of from twenty-six to thirty lectures on the subject of his chair during the winter terms, but owing to the lateness of the hour, 7 P.M., it was unlikely that much work was done in the laboratory by his students. One, at any rate, the poet Shelley, is known to have continued experiments in his untidy rooms in college, while the professor himself worked in the University laboratory at his own researches. Doubtless the dim light of the few candles, or oil lamps, which would have been the only source of illumination then available, as well as the grime of ages on the vaulted ceiling of the laboratory, enhanced that appearance of gloom which has been so often remembered by our visitors during the early years of the nineteenth century, and which was unsuited for the critical operations of analytical chemistry as then practised. But it was not before 1848 that the old laboratory was superseded in Oxford, and the fact remains that for over a hundred and fifty years the Ashmolean had provided England with its first public university laboratory, "the designe of this building being not onlie to advance the studies of true and real philosophy, but also to conduce to the uses of life and the improvement of medicine."

The Old Ashmolean,
Oxford.

The Spinning Electron in Wave Mechanics.

THE new wave mechanics admits the existence in physical phenomena of a variable quantity that satisfies a special differential equation. According to Schrodinger, this function ψ is such that the product $\psi\bar{\psi}$, where $\bar{\psi}$ is the conjugate complex quantity, is the electrical density. On the contrary Bateman (NATURE, 118, 839) has recently shown that, by considering two functions, each of which satisfies the wave equation, it is possible to determine the potentials **a** and ϕ of the electromagnetic field. Starting from Bateman's considerations, de Broglie (*C.R.* 184, 81) has shown that the values calculated with this theory coincide with those of Maxwell's theory if one admits that the frequency of the fundamental functions be very high and that the considered phenomenon be nearly stationary in relation to this frequency. De Broglie, however, has shown that, given the wave-equation

$$\nabla^2\psi - \frac{1}{c^2}\frac{\partial^2\psi}{\partial t^2} - \frac{4\pi^2}{c^2}\nu_0{}^2\psi = 0,$$

putting in the place of the function ψ the two $\psi_1 = \frac{A}{r}\cos 2\pi\nu_0 t$, $\psi_2 = B\sin 2\pi\nu_0 t$, and introducing the potentials

$$a_x = \tfrac{1}{2}\left[\psi_1\frac{\partial\psi_2}{\partial x} - \psi_2\frac{\partial\psi_1}{\partial x}\right], \quad . \; . \; . \quad \phi = -\frac{1}{2c}\left[\psi_1\frac{\partial\psi_2}{\partial t} - \psi_2\frac{\partial\psi_1}{\partial t}\right],$$

the results verify Lorentz's equation

$$\frac{\partial a_x}{\partial x} + \frac{\partial a_y}{\partial y} + \frac{\partial a_z}{\partial z} + \frac{1}{c}\frac{\partial\phi}{\partial t} = 0.$$

We thus obtain for the fields **E** and **H** the expressions

$$\mathbf{E} = -k \text{ grad. } \frac{1}{r}(1 + \cos 4\pi\nu_0 t), \quad \mathbf{H} = 0,$$

that is, the characteristic values of a pole of charge k.

With this new aspect of the theory, though on one hand the two functions ψ_1 and ψ_2 have no longer the properties of ψ and $\bar{\psi}$, on the other there is the advantage of correlating wave mechanics with Maxwell's theory. We may note that, using the above proceeding, it is possible to introduce the spinning electron into this theory. To do so, it should be observed that two quantities ψ_1 and ψ_2 are sufficient, according to Bateman and de Broglie, to produce the electromagnetic field; let us see if it is not better to introduce two four vectors, the components of which would be

$$\psi_{1x} = \frac{A_x}{r}\cos 2\pi\nu_0 t, \quad . \; . \; . \quad \psi_{1l} = \frac{A_l}{r}\cos 2\pi\nu_0 t,$$

$$\psi_{2x} = B_x \sin 2\pi\nu_0 t, \quad . \; . \; . \quad \psi_{2l} = B_l \sin 2\pi\nu_0 t \; (l = ct).$$

By this four vector we form a single four vector U such as

$$U_i = \tfrac{1}{2}\left[\psi_{1i}\frac{\partial\psi_{2i}}{\partial l} - \psi_{2i}\frac{\partial\psi_{1i}}{\partial l}\right] = \frac{\pi\nu_0}{c}\,\frac{A_iB_i}{r},$$

or putting

$$U_x = \frac{m_x}{r} = \frac{\pi\nu_0}{c}\,\frac{A_xB_x}{r}, \quad . \; . \; . \quad U_l = \frac{q}{r} = \frac{\pi\nu_0}{c}\,\frac{A_lB_l}{r},$$

we find that the three special components of the four vector U form a vector $\mathbf{m}/r$, while the fourth component is q/r.

If we now put

$$\mathbf{a} = \text{curl } \frac{\mathbf{m}}{r}, \quad \phi = \frac{q}{r}.$$

it follows easily that

$$\frac{\partial a_x}{\partial x} + \frac{\partial a_y}{\partial y} + \frac{\partial a_z}{\partial z} + \frac{1}{c}\frac{\partial\phi}{\partial t} = 0,$$

and the expressions of the electrical and magnetic fields are

$$\mathbf{E} = -\text{grad. } \phi = -q \text{ grad. } \frac{1}{r},$$

$$\mathbf{H} = \text{curl } \mathbf{a} = \text{curl}\left[\mathbf{m}, \text{grad. } \frac{1}{r}\right];$$

that is, the field produced by a spinning charge q which is equivalent for the magnetic field to a magnetic dipol **m**.

Photochemical Decomposition of Hydrogen Iodide.

THE mechanism proposed by Warburg (*Sitz. der preuss. Akad. der Wiss.*, 300; 1918) for the photochemical decomposition of hydrogen iodide, namely:

$$\begin{aligned}
&(1)\; \mathrm{HI} + h\nu = \mathrm{H} + \mathrm{I}\\
&(2)\; \mathrm{H} + \mathrm{HI} = \mathrm{H_2} + \mathrm{I}\\
&(3)\; \mathrm{I} + \mathrm{I} = \mathrm{I_2},
\end{aligned}$$

has been generally accepted for a long time but has not received experimental confirmation. Warburg obtained a quantum efficiency of two and showed thermodynamically that reaction (2) was the only secondary reaction possible. Reaction chains cannot be set up in view of the non-occurrence of the highly endothermic reaction,

$$\mathrm{I} + \mathrm{HI} = \mathrm{I_2} + \mathrm{H},$$

which thus interrupts the chain.

Still another interpretation is possible, namely, that discussed by Stern and Volmer (*Z. Wiss. Phot.*, 19, 275; 1920), which leads to the same result of two molecules decomposing for each quantum absorbed. Here an activated molecule in colliding with a normal molecule brings about the decomposition of both.

$$(1)\; \mathrm{HI} + h\nu = \mathrm{HI}' \qquad (2)\; \mathrm{HI}' + \mathrm{HI} = \mathrm{H_2} + \mathrm{I_2}.$$

Until now no observation admits of a decision between these two possibilities, since Warburg worked at rather high pressures.

The writer purposed studying the quantum efficiencies at pressures sufficiently low so that a molecule of hydrogen iodide activated by absorbed radiation cannot make a collision with another molecule before its mean free life, namely, 10^{-7} sec. has terminated or before it decomposes of its own accord. In the former case, if reversion takes place, that is, if collisions are a necessary requisite for decomposition, one should expect the quantum efficiency to be very small, of the order 100 to 200 quanta absorbed per molecule decomposing. In the latter case, if it decomposes in a single act, the quantum efficiency should still remain two as at high pressures. The results are markedly different, and it should be easy to distinguish between these alternatives.

Using the 2080 Å.U. and 2530 Å.U. bands of the condensed zinc spark and working at pressure of hydrogen iodide of the order of 0·1 mm. mercury, well below the critical collision frequency pressure, the writer has found the quantum efficiency to be in the neighbourhood of two. The reaction was studied in its initial stages to avoid secondary absorption by iodine set free. The amount of decomposition was ascertained by freezing out all the hydrogen iodide and iodine, and measuring the hydrogen with a calibrated bifilar quartz manometer described by Coolidge (*J. Am. Chem. Soc.*, 45, 1637; 1923).

Thus Warburg's mechanism is substantiated experimentally. Further, this is the first time it has been proved that a polar molecule may dissociate in a single elementary act, thus affording a possible explanation of the continuous absorption spectrum of hydrogen iodide found recently by Tingey and Gerke (*J. Am. Chem. Soc.*, 48, 1838; 1926), and Bonhoeffer and Steiner (*Z. Phys. Chem.*, 122, 287; 1926).

The work is being continued and a more complete account will be published shortly.

The Tomb of Laplace

To those interested in the records and memorials of men of science, Paris, no less than London, presents a most attractive field for exploration. The Sorbonne, the Natural History Museum, the Observatory, the schools, the streets, the squares, and the churches abound with statues and monuments, while here and there can be traced the footsteps of such as Pascal, Lavoisier, and Pasteur. No spot, however, recalls such a wealth of historic associations as that of the famous Père Lachaise-cemetery, where, to mention only those famed in science, lie Delambre, Arago, Bichat, Cuvier, Charles, Brongniart, St. Hilaire, Comte, Chasles, and a score more. It was here also Laplace was buried, and his funeral discourses were pronounced by Daru, Biot, and Poisson. Over his grave was erected, a marble monument ornamented with a star and bearing the names of his great works.

For sixty-one years Laplace lay here, but in accordance with the express wish of his son, in September 1888 his remains were exhumed and re-interred in the grounds of the family estate at Saint Julien de Mailloc, Calvados. The removal seems to have attracted little attention even in scientific circles, and in view of the interest aroused by the centenary of the death of Laplace the following particulars are perhaps worth recording. For them I am indebted to the Comte de Colbert-Laplace, a great grandson of the famous astronomer, who also informs me that on Dec. 11, 1925, a fire completely destroyed the chateau de Mailloc, and with this were lost all the papers and personal relics of Laplace.

Saint Julien de Mailloc is a small hamlet situated between Lisieux and Orbec, Calvados; and it is on a by-road leading from the main road joining those two places that the tomb of Laplace is to be found. Erected in 1887, it is in the form of a Greek temple about fifteen metres high. The inscriptions recall the birth and death of Laplace, his "Mécanique Céleste," "Système du Monde," and "Théorie Analytique des Probabilités." In a bronze urn in the interior is the heart of Laplace, while the tomb also shelters the remains of his wife, his son, his daughter, and other descendants. Laplace's son, Charles-Emile-Pierre Joseph, Marquis de Laplace, who became a general of artillery, died at the age of eighty-four in 1874, but it was he who desired that Laplace should be brought to Calvados. At the time of the reinterment, the monument which had stood for sixty years in the Père Lachaise, was given to the commune of Beaumont-en-Auge, where Laplace was born, and was re-erected in the cemetery there.

In view of the complete destruction of the papers of Laplace in 1925, it may not be out of place to recall that in Nature of June 8, 1871, p. 108, is a note to the effect that housebreakers raided Laplace's old chateau at Arcueil and threw the manuscript of the "Mécanique Céleste" into the River Bièvre, from which, however, it was rescued.

Tetragonal Structure of Carbon Steel.

It has been shown by Westgren, Vewer, and many others that the martensite of carbon steel has only the crystal structure of α iron, and sometimes has simultaneous structures of α and γ iron with carbon in the state of solid solution. Recently Fink and Campbell (*Transactions of the American Society of Steel Treating*, 9, 717; 1926) found the body-centred tetragonal structure with a ratio of axes 1·06 in carbon steel (1·5 per cent. carbon) after quenching in water from 940° C. Our investigations of carbon steel quenching in water show also the body-centred tetragonal structure. The following table gives the carbon content, the temperature of quenching T, the ratio of axes $c = a/b$, and their dimensions a and b:

Per cent.	T. °C.	c.	a. 10^8 cm.	b. 10^8 cm
0 8	1100	1·027	2 851	2·920
1·0	1100	1·051	2·843	2·987
1·2	1000	1·058	2·848	3·010

In the samples of steel having 0·8 and 1 per cent. carbon in addition to the tetragonal structure were found γ iron (in the sample of steel which had 1 per cent. carbon there was no α iron).

From the above table we arrive at the conclusion that the observed tetragonal structure of steel is a solid solution of carbon in the body-centred tetragonal lattice of metal atoms. It is probable that the martensite has always a body-centred tetragonal structure (simultaneously there could be α and γ iron).

Early British Patent Grants.

The contributor of the "Calendar of Discovery and Invention" appearing in the pages of Nature has in the issue for Feb. 26 fallen into a not uncommon error, when he records Mar. 2, 1617, as the date of the first British patent for invention. This certainly is not the case. The reasons that caused the then Commissioners of Patents to start the famous official series of English patents with the year 1617 were purely fortuitous, and in no way endow this particular patent with any special claim to immortality. The researches of Mr. Hulme and others have brought to light a large number of earlier grants, mostly by Elizabeth and James I., but including one (that to John of Utynam for the making of coloured glass) so early as 1449, and it is to this one that the distinction of priority must for the moment be given.

Moreover, the Statute of Monopolies cannot be correctly described as for the first time securing "the sole working or making of any manner of new manufacture within this realm to the true and first inventor." The Statute was passed simply to prevent the Crown making vexatious monopoly grants; it initiated nothing, and expressly exempted from its operation the use of the existing prerogative in respect of new inventions, a prerogative which, as we have seen, had been constantly exercised for many years past.

Prehistoric Archæology in Yorkshire.

In Nature of Mar. 5, p. 364, announcement is made of the proposed formation of an 'out door' museum at Easington, Yorks, by the East Riding Antiquarian Society. The exhibition of 'obsolete farming appliances' is no doubt a praiseworthy object; but one is tempted to inquire when the Mortimer collection is to become accessible for study by those interested in prehistoric archæology? This collection represents the life's work of the late J. R. Mortimer, who excavated a very large number of barrows on the Yorkshire wolds. It ranks with similar collections at Devizes and in the British Museum; but it has not even been seen by most of the present generation of archæologists, including the present writer. The collection is of national importance, and if the people of Yorkshire do not appreciate their good fortune in possessing it, they should hand it over to others who do. A collection in packing-cases is of no use to any one.

The Centenary of the Friction Match.

By Prof. William A. Bone, F.R.S.

Exactly a hundred years ago next Thursday, John Walker, pharmacist of Stockton-on-Tees, recorded in his Day-Book the first credit sale of his newly-invented 'Friction Lights,' which were indisputably the first practical and useful friction matches. This historic record was as follows:

"*Die Saturni Apr. 7th* 1827
No. 30
Mr. Hixon
Sulphurata Hyperoxygenata Frict. 100
Tin Case 2*d*. 1. 2."

There are few scientific inventions which have been more saving of time and trouble to Mr. Everyman, or more generally used the world over, than that of the humble friction match. It is now so cheap and ubiquitous that to offer a light to a stranger on a railway journey is perhaps the commonest of everyday courtesies amongst all classes of society. No one feels the cost of matches; they are supplied gratis almost everywhere, and the vast number wasted passes unnoticed: truly a 'universal aid,' without which we should be thrown back to the inconveniences of the good old 'flint and tinder' days.

John Walker, to whose memory honour is due to-day, was born at Stockton-on-Tees in 1781 and died there in 1857; my grandfather (the late Thomas Hutchinson, *d.* 1893) knew him well. A memoir published by Dr. R. W. Foss ("Archæologia Æliana," vol. 7) says that as a youth he was articled to Mr. Watson Alcock, surgeon of his native town, and that, after completing his apprenticeship, he went to London (doubtless as a student) for a few years, returning to become Mr. Alcock's assistant.

It was during his apprenticeship that John Walker first began to show his scientific proclivities. He was constantly making chemical experiments, attained considerable reputation in the locality as a botanist, and later on took up the study of mineralogy, in which he became very proficient. After his invention of friction matches (or 'friction lights' as he usually called them) had brought him wider fame, as well as the prospect of a fortune, he steadily refused to patent it, being (as Dr. Foss remarked) "a studious, retiring man, caring more to pursue his scientific studies, whether botanising or experimenting in chemistry, than speculating in order to make money."

Although qualified as a surgeon, "an invincible horror to surgical operations," which he never was able to overcome, soon led Walker to abandon that profession, whereupon he spent some years in Durham and York acquiring commercial experience in the employment of wholesale druggists. Eventually, in 1819, at the age of thirty-eight years, he returned to his native town, where he established himself in business as a pharmacist, at No. 59 in the High Street (since 1896 marked by a suitably engraved brass-plate), living in a house on the Quayside, then a pleasant locality but now much dilapidated. Thirty years later he retired from business, having acquired sufficient for all his needs. He died in 1857 at Stockton-on-Tees, and was buried in the churchyard of the neighbouring parish of Norton-on-Tees, where an unpretentious stone marks his grave.

Walker was never married, but lived with a niece who survived him more than thirty years. He was described by a contemporary as "a trim, dapper, little man," of cheery disposition and ready wit; a man rather particular as to fashion in dress, well known at the time of his invention by his brown tail-coat, drab knee-breeches, grey stockings, white cravat and tall beaver hat.

For many years, how Walker came by his invention was scarcely known. According to an account published in a local newspaper in 1852, it was the result of chance. "Mr. Walker was preparing some lighting mixture for his own use when a match, after being dipped in the preparation, took fire by accidental friction on the hearth . . . and the hint was not lost." Also, Dr. Foss said, "On one occasion . . . some chemical mixture he had compounded fell upon the hearthstone and ignited . . ."; moreover, that Walker did not divulge the exact chemical composition of his matches, and that "from a careful search which has been made in his books it has not been possible to find it. . . ." Such, then, was the local tradition more than fifty years ago.

About the year 1890, however, an old Day-Book in Walker's own handwriting was found among a heap of other papers relating to his pharmaceutical business, which gave a new clue as to how he made the invention. This Day-Book covered the period from Aug. 9, 1825, to Sept. 22, 1829, inclusive, during which time the invention was made. It was handed over to me for investigation (1896) together with eight matches, which undoubtedly had been purchased of Walker himself sometime not later than November 1827. I copied all the relevant entries from the book, and made an analysis of the tip of one of the matches, which confirmed a then current belief that he had used a mixture of potassium chlorate and antimony sulphide made into a paste with gum and starch.

The Day-Book also revealed that, so early as 1825, Walker had been selling a mixture of equal parts of potassium chlorate and antimony sulphide to three different persons, but chiefly to a Mr. Vollum, Junr., of Hartlepool. Entries of such sales continued until Dec. 6, 1828, quite independently of those of his 'friction lights,' the first being as follows:

"*Die Saturni Nov.* 19 1825
Mr. Walton Jr. Norton
by Potassa Chlorat. 3 j Ant. sul. nigri 3 j
Muc. g. i. Aqua q. s. ft. pasta
N.B. Excellent. 1. 6."

The "N.B. Excellent" suggests that the composition in question had been made up *experimentally* for some purpose, which had been well answered. There is also strong evidence in the Day-Book that the purpose was percussion powder, because (1), there are six entries during the years 1826–8 of the Mr. Vollum in question purchasing a composition described either as "pulv. percuss" or as a mixture of equal parts of antimony sulphide and potassium chlorate, the name of Vollum not occurring in any other connexion; and (2), all these six entries, as well as the only two others relating to the purchase of such material during the years covered by the book, were in the autumn or early winter months (September to January), when game-shooting is practised, no such entry ever having been made during any other time of year.

Two entries in the book (dated July 26, 1827, and Sept. 12, 1828, respectively) refer to sales to a Mrs. Faber of "*oxygent*^{d}. *matches*" tipped (as is recorded) with chlorate of potash and sugar only. Undoubtedly these refer to the 'oxymuriate or dipping matches' (strips of wood tipped with a mixture of chlorate of potash, sugar and gum, and ignited by contact with strong sulphuric acid) invented by Chancel in 1805, which had been fairly widely used since 1812.

Therefore it seems reasonable to suppose (1), that Walker had occasionally made Chancel's 'oxymuriate matches' to the order of at least one of his customers; (2), that so early as 1825, if not before, he was experimenting on the production of a sporting 'percussion powder,' composed of equal parts of chlorate of potash and antimony sulphide, for certain other customers, more particularly Vollum; and (3) that, having succeeded, it occurred to him to produce a *friction* match by substituting the same composition for the mixture of potassium chlorate and sugar used for tipping the Chancel *dipping* match. It is important also to observe (4) that he never used the term 'matches' in reference to his own invention, which he usually called 'friction lights' (sometimes, however, 'attrition lights'), and (5), that in the first entry in the book of their sale (*q.v.*), there occur the words "No. 30," probably signifying (as I think) the batch-number of the friction lights in question. If this surmise be correct, he probably had been making them for some time prior to the first recorded sale, which (be it noted) was a credit, and not a cash, transaction.

Walker's 'friction lights' were thin splints of wood, three inches long, one-sixth inch broad, and one-twentieth inch thick, tipped with the aforesaid composition of equal parts of antimony sulphide and potassium chlorate, as my analysis has shown. They were sold by him at 100 for a shilling, in a cylindrical tin case, for which he charged an extra twopence (or a shilling for 84 lights *plus* case). With each case was supplied a piece of 'glass-paper,' folded in two, and a 'light' was ignited by pinching its head between the folds, and then suddenly withdrawing it.

In the Day-Book are entered 23 credit sales of friction lights during 1827, 76 during 1828, and 69 during 1829, or 168 altogether. By the year 1829 their fame had reached London; it is said that Faraday had exhibited some of them at a lecture in London "which set the scientific world thinking."

In that year, also, the following notice of them appeared in the *Quarterly Journal of Science, Literature, and Art*, under the title of "Instantaneous Light Apparatus." "Amongst the different methods invented in latter times for obtaining a light instantly ought certainly to be recorded that of Mr. Walker, chemist, Stockton-on-Tees. He supplies the purchaser with prepared matches, which are put up in tin boxes, but are not liable to change in the atmosphere, and also with a piece of fine glass-paper folded in two. Even a strong blow will not inflame the matches, because of the softness of the wood underneath, nor does rubbing upon wood or any common substance produce any effect except that of spoiling the match; but when one is pinched between the folds of the glass-paper, and suddenly drawn out, it is instantly inflamed. . . ." From 1829–30 onwards, Samuel Jones, of 201 Strand, London, made and sold imitations of them as 'lucifers' (a name which Walker always repudiated), saying that they had been "lectured on at the London and Royal Institutions." It is said that Walker, who was always very modest about his invention, even to the extent of thinking it unimportant, did not long afterwards continue to make 'friction lights.'

Such, then, were the nature and circumstances of this most useful invention. Before many years had passed, other claimants to it arose. At one time the late Sir Isaac Holden thought himself to be the original inventor of 'friction matches,' but in a letter which he wrote to the late Mr. Joseph Parrott of Stockton-on-Tees on Feb. 3, 1894 (*after* hearing of the discovery of Walker's Day-Book), of which I have a photograph, he said, "My invention, if so it may be called, was introduced by me in Oct. 1829 in *entire ignorance* of Mr. Walker's." Unfortunately, the Report of Juries of the Exhibition of 1851 contained a judgment by Warren de la Rue and A. W. Hofmann that "The first friction matches or congreves made their appearance about 1832," without even mentioning Walker's prior invention Now the 'congreves,' which were introduced into England from Germany and Austria in that year, were originally invented by a young French chemist, Charles Sauria of St. Lothair (*d.* 1895), who in January 1831 (or nearly four years after Walker's invention), whilst a student at the Collège d'Arc, Dole (Jura), made friction matches containing phosphorus, but (like Walker) he did not patent his invention, which some think was pirated in Germany. In 1884 the French Government recognised Sauria's 'l'Invention des Allumettes Chimiques' by appropriately granting him a 'bureau de tabac'; and a medal was also bestowed upon him by the Academie Nationale Agricole. Unfortunately, except that in 1913 *Punch* published some verses in his honour, so far nothing has yet been done in Great Britain to recognise or commemorate John Walker's invention; but its centenary affords the opportunity of removing this reproach.

Activities of the Medical Research Council.

PERUSAL of the report of the Medical Research Council for 1925–1926,[1] as usual, gives the reader a bird's-eye view of much of the research work which has been carried out in Great Britain on medical and allied subjects during this period. By the system of grants-in-aid to workers in university and hospital laboratories, etc., the Council is enabled to promote research on a much wider variety of subjects than would otherwise be possible; in fact, almost two-thirds of the Parliamentary grant of £135,000 was utilised in this manner, the greater part of the remainder being devoted to the expenses of the National Institute at Hampstead and of the farm laboratories at Mill Hill. Only a few of the more salient points of the report can be touched on in this short account.

Before referring to the scientific work, attention may be directed to certain events of the year which affected the Council. By an Order in Council in July the constitution of the Committee of the Privy Council for Medical Research was altered and the Committee now consists of the Lord President of the Council, the Secretaries of State for Home and Dominion Affairs, for the Colonies, and for Scotland, and the Minister of Health. A few months previously an alteration of the charter of the Medical Research Council had been approved; the amendments provided, *inter alia*, for an increase in the numbers of the Council from ten to eleven, of whom eight are appointed in respect of their scientific attainments, whilst the remaining three include a representative from each of the Houses of Parliament. Two of the former retire each year and are not eligible for immediate reappointment, whilst one of the latter group retires every two years but is eligible for immediate reappointment.

During the year also, the Committee of Civil Research was set up to provide for the discussion of problems which are common to more than one field of science, or to more than one part of the Empire. In addition, representatives of the Medical Research Council were appointed members of the Research Special Sub-Committee of the Imperial Conference and took part in the deliberations of this Committee.

PHYSIOLOGICAL AND BIOCHEMICAL INVESTIGATIONS.

Insulin.—Since the original discovery of insulin by Banting and Best, the problem of the fate of the sugar which disappears under its action from the blood has led to much speculation and stimulated numerous researches, without reaching a final solution until last year. It was known that in the diabetic organism, insulin produced a storage of glycogen in the liver, but in the normal animal the disappearance of sugar from the blood was usually accompanied also by a decrease in the glycogen of this organ; at the same time, examination of the respiratory exchange had shown that, although the metabolism became predominantly carbohydrate in type, yet the oxygen consumption was not sufficiently increased—it might even be decreased—to account for the combustion of all the sugar vanishing. A brilliant series of researches at the National Institute during the past year appears now to have solved this problem.

C. H. Best, in a preliminary investigation on artificially perfused limbs, was able to show that the skeletal muscles were the chief site of the disappearance of sugar. Working with J. P. Hoet and H. P. Marks, he then found that a large part of the glucose disappearing could be found as glycogen in the muscles; although the inorganic phosphate of the blood falls together with the sugar, no storage of phosphoric esters in the muscles was observed. Finally, Best, Dale, Hoet and Marks made a complete balance-sheet of the glucose exchange under the action of insulin. Under all conditions of glucose supply in relation to the dose of insulin, the total amount of glucose disappearing from the system—the decapitated eviscerated preparation—was equal to that burnt, as estimated from the oxygen consumption, together with that found deposited as glycogen in the muscles.

The loss of glycogen from the normal liver under the action of insulin is a secondary effect of the fall in the blood-sugar. In the diabetic with a high blood-sugar, insulin promotes glycogen deposition in the liver, but under its continued action, with a fall in the blood-sugar below a critical level, this glycogen will be transferred, as sugar, to the muscles. The liver glycogen acts as a carbohydrate reservoir, easily available if the blood-sugar falls; muscle glycogen, on the other hand, does not appear to have this function. The depression of the total metabolism under the action of insulin, mentioned above, is most easily explained on the assumption that insulin restrains the new formation of carbohydrate from protein, or fat (Burn and Marks), in the liver. It may therefore be concluded that the action of insulin is identical in both the normal and the diabetic organism.

A very interesting observation has been made by Hoet and Marks, as an incidental outcome of this work on insulin. It has been known for some time that animals dying from an overdose become rigid almost immediately. This also occurs when a rabbit dies after daily thyroid feeding for some weeks. In both cases there is almost complete exhaustion of the muscle glycogen; the *rigor mortis* sets in also whilst the muscles are still alkaline. It appears that the rigidity is due to a failure to reform the hexose-phosphate or 'lactacidogen,' from a shortage of the raw material, the glycogen. Under ordinary conditions the muscle enters into *rigor* only some time after death, and with an acid reaction; in this case the cause must be sought in the death of the synthetic mechanism.

Histamine.—Since the discovery by Dale, Laidlaw, and Richards that histamine, whilst stimulating smooth muscle, relaxes the walls of the capillaries, leading to a marked fall of blood pressure, interest in this substance has been maintained, more especially since it was probably responsible for many of the cases of 'shock' seen during the War. More recently it has been suggested that it may have therapeutic applications. It has been known for many years that extracts of most tissues cause a fall in the blood pressure; recently a liver extract has been advocated as a therapeutic measure in high blood pressure in man. Best, Dale, Dudley and Thorpe have succeeded in identifying the active principles of liver extracts and have found them to be histamine and choline. In addition, large amounts of histamine have been extracted from fresh lungs, *e.g.* 0·3 gm. from 10 kgm. of lung. It must be remembered in connexion with these quantities that 1 part in 250 million parts of water can produce contraction of the smooth muscle of the uterus.

---

[1] Committee of the Privy Council for Medical Research. Report of the Medical Research Council for the Year 1925–1926. Pp. 161. (London: H.M. Stationery Office, 1926.) 3*s*. 6*d*. net.

The physiological function of histamine in the body is still a subject for research, but it may be suggested that it plays a part in the chemical control of the capillary circulation, perhaps as an antagonist to adrenaline. This suggestion is supported by the work of Sir Thomas Lewis and his colleagues; they have found that the local reaction of the skin blood-vessels to irritation or injury can be exactly imitated by the injection of minute amounts of histamine.

BACTERIOLOGICAL INVESTIGATIONS.

Cancer.—The work of Gye and Barnard on the filter-passing virus of cancer has been continued. It will be remembered that Gye, working with the Rous chicken sarcoma, found evidence which he believed could only be explained on the hypothesis that the cell-free filtrate from the tumour contained two factors, either of which alone was innocuous. One was a thermolabile substance, specific to the species from which the material was derived; the other was a filter-passing virus, which could be obtained also from mammalian tumours. Gye's recent work has confirmed his original observations; thus he has been able to destroy the virus by using antiseptics like acriflavine or cyanides, instead of chloroform, leaving the specific factor intact in the solution. Some parts of his work have been confirmed by other investigators, other parts are unconfirmed or the validity of his evidence denied. Only further experiments can settle the conflict of testimony.

Dog Distemper.—P. P. Laidlaw and G. W. Dunkin have continued their investigations into canine distemper; the work is greatly aided by the fund collected by the *Field* newspaper. It is now quite certain that the disease is caused by a filter-passing virus; unfortunately, no means have yet been discovered of cultivating it *in vitro*. It can, however, be transmitted to ferrets and back again to dogs at will. The ferret can be immunised by inoculation with formalin-treated virus and is then usually protected against what is an almost invariably fatal disease in this animal. On the other hand, attempts to immunise dogs have been less successful; but it is hoped that a primary inoculation of dead virus followed by a mild distemper infection while the animal is refractory to the disease, will develop sufficient resistance to protect the animal against chance infections.

Chemotherapeutics.—In conclusion, attention may be briefly turned to one or two chemotherapeutical investigations. S. R. Douglas has shown that sanocrysin (sodium gold thiosulphate) has not a specific action on the tubercle bacillus, but so affects the cells of the tubercular lesions as to give indirect damage to the infecting organisms; in rabbits, S. L. Cummins has found that mild infections can be eliminated by this drug, but heavy or virulent infections cannot be cured. In another direction Dobell and Laidlaw, utilising their method of cultivating entamœbæ *in vitro*, on media containing solid rice-starch, have shown that emetine and cephæline are specifically poisonous to *E. histolytica*, the causal organism of amœbic dysentery in man. Minute quantities inhibit its growth and ultimately destroy it, but relatively strong concentrations are necessary to kill it at once. The importance of this time factor in the treatment of the human disease is obvious.

Obituary.

DR. A. W. CROSSLEY, C.M.G., C.B.E., F.R.S.

DR. ARTHUR WILLIAM CROSSLEY, who died at his residence, Thorngrove, Alderley Edge, Cheshire, on Saturday, Mar. 5, at the relatively early age of fifty-eight years, was the son of the late Richard Crossley and was born at Accrington on Feb. 25, 1869. His early education was obtained at Mill Hill School, from whence he proceeded to the Owens College, Manchester, then part of the federated Victoria University, where he graduated in the honours school in 1890. It is evident that thus early in his career his tastes inclined towards the organic side of chemistry because, after graduating, he went to Würzburg to work under Emil Fischer, then well on the way towards the zenith of his fame, and from there published his first paper, a short note on the optical behaviour of dulcitol, in 1892. He graduated Ph.D. at Würzburg in 1892 and then followed Fischer to Berlin, from which University he published his second paper, on the oxidation of mucic acid, in 1894.

In the autumn of 1894, Crossley returned to Manchester to work with the younger Perkin, who had two years previously succeeded Schorlemmer in the chair of organic chemistry and had started the Manchester school of organic research, which was afterwards to become world famous. He was awarded a Bishop Berkeley fellowship, which, however, he relinquished in the following year on his appointment as lecturer in chemistry at St. Thomas's Hospital; nevertheless, during his short stay in Manchester, he completed an important paper on the substituted pimelic acids, which he published conjointly with Prof. Perkin in 1895. During the time he remained at St. Thomas's Hospital, that is, until 1904, when he was appointed professor of chemistry to the Pharmaceutical Society of Great Britain, he published several papers on the malonic ester condensation, mainly in connexion with the formation of hydro-aromatic compounds. This work was evidently the outcome of that which he had started earlier with Perkin on the constitution of camphor—a problem at that time occupying the full attention of Perkin's school at Manchester. It appears that Crossley completed this camphor work at St. Thomas's, for it is embodied in a paper on dihydrocamphoric acid published with Perkin in 1898, and that, moreover, the peculiar properties of dihydrocamphoric acid decided him to subject a whole series of hydro-aromatic substances to special investigation.

In this way Crossley's life work, so far as organic chemistry is concerned, was determined, and we find a number of papers from his pen appearing at regular intervals from 1896 until 1914, in which year he was appointed Daniell professor of chemistry at King's College (University of London). The insight and manipulative skill shown by these researches place Crossley in the front rank of modern organic chemists and would have enabled him to accomplish far greater achievements had not fate determined otherwise, for the advent of the War directed his energies into other channels of wider and more urgent importance. During his stay at St. Thomas's Hospital he was associated in his research work with Henry Rondel Le Sueur, and while at the Pharmaceutical Society, with Charles Gilling and Nora Renouf, with whom he published many important papers. He was awarded the D.Sc. of the Victoria University in 1899, and was elected fellow of the Royal Society in 1907. He received the Longstaff medal of the Chemical Society in 1918.

Shortly after the outbreak of War, the Royal Society formed a committee to render the Government any assistance that might be necessary on the scientific side, but after the first definite use of gas in April 1915, it was evident that special measures would have to be taken to meet the new menace. On the formation of the Trench Warfare Department under Colonel (now General Sir Louis) Jackson, Crossley was nominated by the Royal Society as a member of the Advisory Committee of the Department and became its first secretary. Early in 1916 it was realised that the trench warfare experimental grounds at Clapham Common and Wembley were too small for the purposes of large-scale experiments, and were, moreover, situated in areas too congested to warrant the use of materials likely to be dangerous to health. Search led to the discovery of a tract of land of poor agricultural value situated between the London Road and the railway about two miles from Porton in Wiltshire, and here, in the spring of 1916, it was decided to establish an experimental station for investigations in connexion with chemical warfare.

The problems requiring solution were urgent and complex, the power and safety of our armies in the field depending upon the provision of offensive and defensive appliances in the shortest possible time. Nothing existed on the ground but a few farm buildings and out-houses, and everything from a gun range to a drainage system had to be provided as quickly as possible. Crossley undertook to put things in order, and for this purpose he was given the rank of Lieutenant-Colonel R.E. Here, then, with a band of devoted helpers, he started to carry through what was in all probability the most difficult task of his life, requiring as it did the exercise of infinite tact and a power of control over men such as few, especially those trained in academic surroundings, possess. It was, indeed, a prospect which the boldest might have hesitated to face. Nevertheless, Crossley played his part as a soldier with all the energy and force with which he did everything else, and brought to bear a personal charm of manner which enabled him, although a strict disciplinarian, to endear himself to all the officers and civilians serving under him. It was due to him and those with him that within a comparatively short space of time the experimental station at Porton became a real factor in the War, and that it was established on a basis which not only caused it to be the centre of chemical warfare research in Great Britain, but also enabled it to serve as a model on which similar organisations have been built in other countries.

It was the present writer's lot to form one of the group of five who walked from the London Road into that peaceful valley one Sunday in February 1916, and also to be one of those who was present when His Majesty the King visited the station in 1918. No one who has not undergone these two experiences can realise the change Crossley had wrought in the time. For some considerable period he acted as liaison officer with the French and he visited the front on many occasions. His work also necessitated frequent consultations with the chemical advisers to the armies, and for this purpose he made many visits to St. Omer and Paris Plage. Later, the increase of work at Porton required his full attention and he delegated his French work to others. For his services to the French Government he was created an Officier de la Légion d'Honneur on the occasion of the visit of the Chemical Warfare Advisory Committee, which had now become part of the Ministry of Munitions, to Paris. He was created C.M.G. in 1917, and C.B.E. in 1919.

During the War the Department of Scientific and Industrial Research, which had been established as a Committee of the Privy Council in 1915, decided to form industrial research associations in order that, after the War, there might be an organised effort, backed by the latest scientific methods, to meet the competition which would then arise. Among these, one of the latest to be formed was that constituted in 1919, dealing with the cotton industry, for which, in the following year, the house at Didsbury, Manchester, afterwards known as the Shirley Institute, was acquired. Crossley was appointed first Director of the Association, and here, as at Porton, he was faced with the problem of creating an organisation from the beginning. The Shirley Institute comprised a large private house situated in its own grounds but bearing no semblance to a scientific institution. He had to undertake the difficult task of installing laboratories and equipment which could deal effectively with the problems arising in this basic industry. Such problems would necessarily cover a wide field, including many branches of science, and would, therefore, entail the initiation and control of researches in subjects other than chemistry. He had not only to help the industry by research on scientific lines, but also had to accomplish the still more delicate task of appealing by the work of the Institute to those who were anxious for immediate practical results and were not always cognisant of the essential need for fundamental research as a foundation for industrial progress. It is a remarkable fact that in two years, that is to say, in approximately the same time as was taken to organise Porton, the Shirley Institute was established as a fully equipped research unit and was formally opened by the Duke of York in 1922. Since then the volume of research work from the Institute has not only made it a model research association, but has also, by reason of the practical application of its work, convinced many who were previously sceptical of the value of fundamental research in relation to the industry.

Despite his many other activities, Crossley found time to devote himself to other public work, and was from 1903 until 1913 secretary of the Chemical Society and from 1913 until 1925 its foreign secretary. In the latter year he was president of the Society, but had to relinquish the office after one year owing to failing health. He was a man, therefore, who gave great and useful service to his country, and received the recognition of his King, his University, and his fellow scientific workers. Had he lived he would have attained to greater honours, for the full power of his work will not be realised until the lapse of time has proved its value. Without question his life was shortened by his devotion to public duty and by the strain imposed on his constitution by the high sense of responsibility he felt in all the work he undertook. The War years imposed a heavy burden, which, although cheerfully borne, nevertheless left its mark on a not too robust constitution, and he never seemed quite the same man afterwards. He was essentially a pioneer, for his great activity of mind led him to seek new problems as soon as he had settled the one in hand to his own satisfaction and had brought it to a stage at which he felt he could safely hand it over to others. He was denied, therefore, the complacent rest which ought to follow the contemplation of smoothly running administrative machinery well and truly constructed J. F. T.

M. F. E. Turpin.

M. François Eugène Turpin, well known as the inventor of melinite, one of the high explosives used in shell-filling, died on Jan. 24 at Pontoise. We are indebted to a recent issue of *La Nature* for the following particulars of his life. After his birth at Rosendael in 1849 his parents moved to Paris, where, on leaving school, he began to study medicine. But he became interested in chemical research, and it was not long before his natural skill in experimental work was publicly recognised by the bestowal upon him by the Paris Academy of Sciences of the Montyon prize for his invention of harmless colouring matters for children's toys. This invention presently involved him in some litigation, but, nothing daunted, he applied himself with energy to the study of explosives. Those were the days of black gunpowder, dynamite, and gun-cotton. The instability of nitrated organic compounds had rendered them unfit for use by the artillery and even unsafe to store in magazines. With the object of overcoming these difficulties Turpin decided to abandon the search for suitable material among aliphatic compounds and turned his attention to those of the aromatic series. After seven years of ceaseless toil he perfected a process for preparing a suitable high explosive from picric acid by the simple device of melting it in an oil-bath and running it into moulds. When, shortly afterwards, a suitable detonator had been devised for use with the new explosive, the French Government purchased the new process from him; but the secret appears to have been treacherously revealed to a British firm by an artillery officer, whom Turpin vigorously denounced in a volume entitled "Comment on a vendu la mélinite." For this indiscretion Turpin was prosecuted, and eventually condemned to prison on the charge of having revealed in his book secrets of importance to the national defence. After spending nearly two years in prison he was pardoned in 1893, and in 1901 he was completely restored to favour by being elected to serve as a technical adviser to the artillery. In this capacity he rendered invaluable service to France until after the War, when the State awarded him an annuity.

Prof. Carl Graebe, who died after a long illness on Jan. 19 in his native town, Frankfort, within a few weeks of completing his eighty-sixth year, had for many years occupied with distinction the chair of chemistry at Geneva. Graebe's reputation was made by his brilliant researches on the constitution of aromatic and heterocyclic compounds, particularly on quinones, phthalic acid, alizarin, and acridine. He also succeeded in demonstrating the constitution of anthracene, phenanthrene, fluorene, carbazol, etc., and was a pioneer in the investigation of the relationship between colour and chemical constitution. Having shown that alizarin was derived not from naphthalene but from anthracene, the synthesis of that important dyestuff could not be long delayed, and the solution of this problem in 1868 by Graebe and Liebermann marks an important stage in the development of the dyestuff industry. Graebe was also the author of a work on the history of organic chemistry.

News and Views.

There is now real ground for hope that a new measure for the protection of wild birds in Great Britain may reach the Statute Book within the next few months and so come into force on Jan. 1, 1928. The Wild Birds Protection Bill received a second reading in the House of Commons on Mar. 25, and is referred to a standing committee. Ever since the Departmental Committee on the subject reported in 1919, legislation on these lines has been pending. Several bills, not greatly differing from the present one, have been introduced, and have made progress in varying degree: they have eventually failed not through opposition but merely on account of the exigencies of parliamentary time. On this occasion the crucial stage has been survived, and if the Bill is given sympathetic treatment in committee, there should be no difficulty in its receiving a third reading and then passing through the House of Lords.

We published a full account of an earlier form of the measure two years ago (Nature, June 20, 1925, p. 934), and a brief indication of the scope of the present Bill will here suffice. Some general protection is given to all birds by the prohibition of destruction and capture by certain methods and at certain times and places. Special protection, further, is given to different species according to the categories in which they are classified for the purpose. Birds in Category I. and their nests and eggs are protected at all times. Birds in Category II, with their nests and eggs, are protected during the close season, normally Mar. 1–July 31. Birds in Category III., but not their nests or eggs, are protected during the close season except against the owner or occupier of the land or his agents. Named as coming within the first category are the greater rarities, some much persecuted species, and a few others: in the second are birds which especially need protection in the breeding season. The third category comprises all birds not scheduled as belonging to the first or second. The Bill will supersede the existing legislation on the subject. Its great merits are its simplicity, the uniformity which it will introduce, and the better powers given for enforcement. These should lead to a much greater effectiveness in practice.

It is noteworthy, from the report of the debate on the second reading of the Protection of Wild Birds Bill, that such opposition as there was, apart from points of detail which will be raised again in committee, mainly arose not from objection to the proposed provisions but from a desire for a still wider measure. The protection of all birds at all times, apart from such few species as might have to be blacklisted, was indeed suggested. The Bill as it stands, however, seems to achieve a wise moderation. It gives absolute protection where it is most needed, and some measure of protection to all birds: it avoids the unnecessary creation of new offences, and the imposition of excessive restrictions which would tend to alienate that public opinion upon which the successful working of a law of this kind must largely depend.

Among the great City Companies of London there is none more closely associated with pure and applied science than the Goldsmith's Company, which this week is celebrating the six-hundredth anniversary of its foundation. By a happy coincidence, the Prime Warden of the Company this year is Sir Dugald Clerk, who presided at the banquet held on Monday, and one of the Wardens is Sir William Pope, who will become Prime Warden the year after next. Other fellows of the Royal Society who have been Prime Wardens of the Company are Mr. George Matthey, Sir Frederick Bramwell, Sir Frederick Abel, Sir J. Wolfe Barry, and Mr. C. T. Heycock. In October last we described an extension of the City and Guilds (Engineering) College at South Kensington, provided by the munificence of the Company at a capital cost for building of £87,000. The Company also heads the list of grants made by city companies to the City and Guilds Institute with total grants amounting to £204,500, and these represent only part of the generous provision made by the Company for progressive education and science. We have often expressed appreciation of the encouraging attitude constantly displayed by the Company towards scientific activities, and we are glad to offer it our most cordial congratulations upon the wise purposes for which it employs its funds and upon the strength of its present position in national life.

The interesting collection of prehistoric stone implements from Suffolk, the South Downs, and other British localities formed by Mr. S. G. Hewlett during twenty-five years of personal collecting, has recently been sold at Stevens's auction rooms. Although dispersals are especially to be regretted when objects of local importance are thereby removed from their proper homes, they afford an excellent opportunity for appraising the value which the public sets upon the specialised collections and researches of others. Truth to tell, this sale has shown that these stony and enduring records of early but barbaric man are very far behind the ephemeral postage stamps of his civilised successors in the public estimation. No single implement fetched more than £3. Close on two hundred and fifty lots, comprising 6000 'flints,' passed under the hammer for a total of £293 : 9*s*. In detail, 287 palæoliths brought £25 : 4*s*., and 1076 neoliths, mostly from the eastern counties of England and the Thames Valley, brought £103 : 17*s*., an average of ten to a £1. Those from the South Downs, with others, were sold at about thirty to a £1, and some 300 from abroad only fetched £15 : 1*s*. For years we have been stimulated by the sight of long series of such specimens beautifully set out in museums in expensive cases, to wander across ploughed fields and gravel heaps looking in vain for flints that never turned up, but which we had come to regard as of great value. Can it be that the reward for finding them is so small as the Hewlett sale would lead us to suppose? If so, flint-collecting is certainly an appropriate hobby for a poor man of science.

Following closely on the announcement of the purchase by the Zoological Society of London of part of the Ashridge Estate as the site for a new Zoological Park, comes the news that Mr. G. B. Chapman, the well-known animal dealer, has purchased the "Withdean Hall" estate, on the London-Brighton Road, which he intends to form into a public zoological gardens. Considering the enormous interest which is taken in animals of all kinds in Great Britain, there is a notable lack of zoological gardens as compared with many other countries, there being only five in Great Britain, while in Germany there are more than twenty, and as many as ninety-two in the United States. Mr. Chapman's new gardens will be laid out on modern lines and the animals will be exhibited under the most natural conditions possible. Cages and bars will be to a great extent eliminated, and their place will be taken by wide ditches over which the animals cannot pass. Mr. Chapman is to be congratulated on his enterprise in providing for the public what will not only be a place of enjoyment and recreation, but also one of the highest educational value.

Prof. E. T. Whittaker delivered a lecture on "Present Conceptions of the Cosmos" at Bedford College for Women (University of London) on Mar. 22. Cosmology was founded, he said, in the fifth century B.C. by the Pythagoreans, who first put forward the idea that the earth was spherical; the difficulties they experienced in proving this statement are analogous to our difficulties in establishing present-day hypotheses concerning the size and nature of the whole universe of stars and space. Since the days of the Pythagoreans we have been convinced by experimental evidence that the earth is round and finite, so that there cannot be more than a maximum distance between two points on its surface. The methods of investigation, with the exception of the geodetic, depend on observations made outside the earth, but in considering the whole universe we have no external system of reference. We are apt to be misled by early education, which often implants *a priori* notions concerning space, and obscures the fact that the axioms on which Euclidean geometry is based are not necessarily true from all points of view. Systems of non-Euclidean geometry also have practical applications, and it is possible that on one of these systems as a basis, space may be found to be finite. The distinction between being finite and being unbounded must be clearly made. Space may very well be finite, yet with no boundaries; the traveller through space, unconscious that he is not moving in a straight line, may yet return eventually to his starting-point.

Since the Victorian age, Prof. Whittaker continued, the theory of relativity has produced a definite advance in the interpretation of the cosmos in terms of a non-Euclidean system. This theory helps to elucidate observations made on the astronomical universe. The number of stars, though immense, is not infinite, and their distance from the earth can be measured. The earth is situated in the Milky Way or galactic system, and the nearest star is at a distance of about four light years. The spiral nebulæ, first discovered by Lord Rosse in 1845, are the most distant objects yet observed and are right outside the galactic system; the latter has a diameter of roughly three-quarters of a million light years, while the spiral nebulæ are at a distance of from one to ten million light years. It has long been known that the motion of stars towards or away from the earth can be deduced from the shift of the spectral lines; a shift towards the red has been observed in the spectra of the spiral nebulæ, and it is therefore concluded that they are moving away from the earth. Einstein's theory of relativity, based on a non-Euclidean system, brings into account the possible curvature of the universe and predicts that a shift of the spectral lines towards the red will be observed for all bodies at a great distance. The diameter of the universe has been estimated from the spectral observations, and is found to be of the order of one hundred million light years. From this point of view, therefore, the universe, though remaining unbounded, may be said to be of a finite nature.

In his Friday evening discourse delivered at the Royal Institution on Mar. 25, Prof. C. T. R. Wilson stated that much may be learnt about the processes which are going on in a thundercloud by observing the sign and magnitude of the electric field which it produces at the surface of the earth and the sudden changes which lightning discharges cause in this field. These changes are generally of the order of 10,000 volts per metre below the central portion of the thundercloud, of the order of 1000 volts per metre at a distance of 10 kilometres, and they become comparable with the fine weather field of 100 volts per metre at about 20 kilometres. The fields destroyed by lightning discharges are most frequently negative below the thundercloud and positive at great distances. Thunderclouds seem to be essentially bipolar, with the positive charge above the negative. Discharge may occur between the upper and lower poles, between the ground and the lower or more rarely the upper pole, or between the upper pole and the upper atmosphere; combinations of these, either simultaneous or in rapid succession, also occur. From the magnitude of the sudden changes produced in the field by lightning discharges at known distances, the electric moments of the discharges (depending on the quantities discharged and their heights) may be determined. These generally exceed 30 coulomb-kilometres. The quantity discharged in a lightning flash is of the order of 20 coulombs. The potential difference developed in the cloud before discharge is of the order of one million kilovolts, and the energy spent in a lightning discharge is about 10^{17} ergs or 10^{10} joules. Nearly 2000 thunderstorms are on an average in action at a given time, and they may, perhaps, be the main sources of the downward current and positive potential gradient of fine weather regions. In a thundercloud, on account of the great distance through which the intense electric fields extend, effects may be possible which we cannot hope to produce in the laboratory. It may, for example, be possible for electrons to be accelerated until their energy is some hundreds of times as great as that of any known β-particle.

BY electing Dr. H. H. Woollard, at present assistant professor of anatomy and sub-dean of the Faculty of Medical Sciences at University College, London, to the chair of anatomy just vacated by Prof. Wood Jones, the University of Adelaide has once more deprived England of one of her best anatomists, who can ill be spared. Dr. Woollard obtained his M.D. in the University of Melbourne and served throughout the War in the Australian Medical Corps at Gallipoli and in France, eventually attaining the rank of Lieut.-Colonel and being awarded the Croix de Guerre avec Pâlme. After the War he joined the postgraduate class of anatomy at University College, London, and was invited to join the staff of the Department. He spent the academic year 1921–22 at Johns Hopkins University as a Rockefeller Foundation Fellow, and on his return to University College was made assistant professor. In addition to a monograph on the anatomy of Tarsius, in the main corroborating and extending the pioneer work of Burmeister, he has made exact histological surveys of the cerebral cortex of Tarsius and Orycteropus, and a detailed comparative study of the visual apparatus (retinal and cerebral) in the primates, yielding results of far-reaching value and importance for the student of human evolution. But perhaps his most distinctive achievements are his researches (in particular his application of the methylene-blue technique) on the double innervation of the heart, blood vessels, and striated muscles.

THE Prime Minister's appeal, issued by the Royal Society of Arts, for funds to ensure the preservation of ancient cottages throughout Great Britain, is one which should secure the hearty support of all lovers of beauty, as well as of those who appreciate the fact that these fast-vanishing relics of a bygone day have a value greater than the mere charm of their antiquity to those who seek to interpret the social and economic history of England in the past. Scarcely any material evidence which has survived from those earlier days can serve equally to throw light upon the conditions of agriculture, of rural industry, and of the labourer during the last two to three hundred years or more. Mr. Baldwin's appeal is supported by Mr. Thomas Hardy whose long and intimate acquaintance with rural conditions lends weight to his contention that the ancient type of mud-built cottage is superior to the modern brick structure, not merely on the ground of æsthetic considerations, but also in comfort. The appeal briefly outlines a scheme whereby the fund will endeavour to assist owners financially in securing fitting attention for these ancient cottages and the machinery by which an advisory council will work under the council of the Royal Society of Arts. Donations should be sent to the Secretary, Royal Society of Arts, John St., Adelphi, W.C.2.

THE centenary of the death of Ernst Florens Friedrich Chladni, who has often been called the father of modern acoustics, occurs on April 3. Chladni was born in Wittemberg on Nov. 30, 1756, and died at Breslau on April 3, 1827. His father was professor of law at Wittemberg, and it was in accordance with his wishes that Chladni also studied law. His natural inclination, however, was towards science, and he once wrote: "As an admirer of music, the elements of which I had begun to learn rather late, that is, in my nineteenth year, I noticed that the science of acoustics was more neglected than most other portions of physics. This excited in me the desire to make good the defect, and by new discovery to render some service to this part of science." He then goes on to show how he initiated the experiments on plates set in vibration in various ways. Taking a hint from the work of Lichtenberg of Gottingen, who had sprinkled fine powders on electrified planes, Chladni obtained those beautiful patterns which are given in most text-books. He next invented two new instruments, the euphone and the clavicylinder, and he spent a good deal of his time travelling and explaining his discoveries. Some of the experiments of Chladni were made known in a book published at Leipzig in 1787, but his fame is mainly due to his "Die Akustik" of 1802. When he visited Paris in 1808, Chladni had an opportunity of explaining his discoveries to Napoleon, who asked the Institute to report on them, and allocated 6000 francs for the translation of the work of Chladni into French. Chladni is also remembered for his views on meteors. His portrait forms the frontispiece of Tyndall's book on "Sound."

AMONG the most active of the scientific bodies of the south-west of England is the Royal Cornwall Polytechnic Society, which has recently issued its ninety-third annual report. Though like similar societies it has its lectures and papers, the Polytechnic Society also maintains a Meteorological Observatory and encourages both art and science in the county by holding exhibitions and awarding prizes, medals, and certificates. The exhibition is held at the same time as the summer meeting, and is supported by the Education Committee of the County Council. The present president of the Society is Viscount Falmouth, and the report contains his address in 1925 on the "Development of Physical Science," in which he traced the work of Rontgen, von Laue, Bragg, Rutherford, and others. Two papers reported in full are those on "The Mining Coinage of Cornwall," by Mr. Newton, and "Boulton and Watt in Cornwall," by Mr. Hamilton Jenkin. Towards the end of the eighteenth century there were more than 400 mines in Cornwall, and from these, practically all the copper used in England was obtained. It was the shortage of government coinage which led to the use of local coins and tokens, and it is of interest to note that many of these coins were made in Birmingham by Boulton and Watt, who were then busily engaged installing their engines in the mines. The Polytechnic Society possesses a large number of letters of Boulton and Watt, and Mr. Jenkin's paper was based on these. Boulton and Watt met with great opposition in Cornwall, and the troubles drove Watt to distraction. Boulton's instructions to their representatives in Cornwall when carrying out a steam trial are probably unique, for they begin: "Give a drink to all necessary persons and knock any man down that touches the coal or the fire during the whole trial," and ends with "We pray God send you a good deliverance."

His Majesty the King has approved the award of the Royal Medals of the Royal Geographical Society for 1927 as follows: *Founder's Medal*: to Major Kenneth Mason (Survey of India) for his connexion between the surveys of India and Russian Turkestan through the Pamirs in 1913 and his organisation and conduct of the Shaksgam Expedition of 1926; *Patron's Medal*: to Dr. Lauge Koch (Copenhagen) for his remarkable six years' exploration of northern Greenland. The Council has made the following awards: *Victoria Medal*: to Col. Sir Charles Close for his distinguished contributions to the advancement of the science of geography; *Murchison Grant*: to Mr. John Mathieson for his surveys of Spitsbergen and for his special studies during his long service with the Ordnance Survey in Scotland; *Back Grant*: to Capt. A. H. MacCarthy for his preparation and leadership of the ascent of Mount Logan, 1925; *Cuthbert Peek Grant*: to Mr. Francis Rodd to assist him in further exploration of the Sahara; *Gill Memorial*: to Mr. A. E. Young for his development of the mathematical theory of map projections.

At the annual general meeting of the Chemical Society held on Mar. 24, Prof. H. B. Dixon, Prof. G. G. Henderson, and Prof. A. Smithells were elected new vice-presidents, and Mr. M. P. Applebey, Mr. E. R. Bolton, Prof. J. E. Coates, Prof. J. C. Drummond, Dr. E. K. Rideal, and Prof. J. F. Spencer as new ordinary members of council. Prof. H. B. Baker delivered his presidential address entitled "Experiments on Molecular Complexity," which will appear in the *Journal of the Chemical Society* for April. The anniversary dinner took place the same evening at the Hotel Victoria. The toast of the Society was proposed by Viscount Sumner, while the toast of the guests, proposed by Sir William Pope, was responded to by Sir Ernest Rutherford, Prof. C. Matignon, representing the Société Chimique de France, and Prof. Wilhelm Schlenk, president of the Deutsche Chemische Gesellschaft.

The next meeting of the International Astronomical Union will be held at Leyden, Holland, commencing on July 5, 1928.

The council of the Geological Society of London has this year awarded the proceeds of the Daniel-Pidgeon Trust Fund to Mr. William Elgin Swinton, who proposes to undertake the comparison of British Mesozoic Reptilia with those from similar deposits on the continent of Europe.

On Feb. 24 a dinner was given in honour of Dr. A. P. Coleman, professor emeritus of geology, University of Toronto. It was arranged by some of his colleagues, former students, and other friends, and it was the occasion of the presentation to the University of Toronto of a portrait of Prof. Coleman, and also of a fund for the maintenance of a gold medal to be known as the Coleman Medal. This medal is to be awarded annually to the student who has obtained, at the time of graduation, the highest standing in his class in geology and mineralogy.

Mr. Henry Thomas Tizard, Principal Assistant Secretary, Department of Scientific and Industrial Research, has been appointed by His Majesty the King in Council to be Secretary to the Committee of the Privy Council for Scientific and Industrial Research on the retirement of Sir H. Frank Heath from that office on June 1 next.

Mrs. Bateson, widow of the late Dr. W. Bateson, Director of the John Innes Horticultural Institution, Merton, would be glad of the loan of letters written by Dr. Bateson to any readers of Nature. The letters would be copied and returned without delay unless copies themselves are sent. We are sure that any readers who possess such letters will be glad to assist Mrs. Bateson to bring together correspondence of personal or scientific interest carried on with Dr. Bateson. Communications should be addressed to her at 25 Bolton Gardens, London, S.W. 5.

The National Research Council of the United States recently granted authority for the establishment of a general committee on the physics of the earth. A number of subsidiary committees have already been elected to deal with such topics as the figure of the earth; seismology; terrestrial magnetism; the age of the earth; the internal constitution of the earth; meteorology; oceanography; and volcanology. The committees are largely American in constitution, but several British scientific workers have been included. Dr. Alfred Harker (Cambridge) has been invited to join the sub-committee on volcanology; Prof. Arthur Holmes (Durham) that on the age of the earth; and Dr. Harold Jeffreys (Cambridge) that on the internal constitution of the earth. The results of the work of the various committees will be published in the Bulletins of the National Research Council.

Exeter has been chosen this year as the centre for the meeting at Easter for regional survey study usually organised by Leplay House. The choice has been determined by the fact that Leplay House and the University College of the South-West at Exeter are co-operating in a regional survey of the south-west of England which, it is hoped, may have a considerable practical effect on the future development of this part of the country. An attractive scheme of study has been planned to cover the period April 14-23, which will include, in addition to the usual lectures and opportunities for individual study, visits to Dartmoor, Crediton, Topsham, and possibly Teignmouth, Dartmouth, and Brixham, thus covering a variety of types of geographical, economic, and industrial conditions in the area. Arrangements are also being made for a summer meeting at Warwick on Sept. 7-17. Particulars of membership, etc., may be obtained from the Secretary, Leplay House, 65 Belgrave Rd., S.W.1.

The council of the Institution of Mining and Metallurgy has made the following awards: The Gold Medal of the Institution to Prof. William Frecheville, in recognition of his services to the mining industry during a long and distinguished professional career, and to mining engineering education; The Consolidated Gold Fields of South Africa, Ltd., Gold Medal and Premium to Dr. Sydney W. Smith, for his paper, embodying much original research, on "Liquation in Molten Alloys and its possible Geological Significance"; and the Arthur Claudet Students' Prize to Mr. Robert A. Mackay for a paper on "The Influence of Superimposed Strata on the Deposition of Certain Lead-Zinc Ores."

The Report of the Secretary of the Smithsonian Institution, submitted on Dec. 9 last, records the acquisition of the Dognin collection of Lepidoptera, by means of gifts from friends amounting to 50,000 dollars. The collection contains 82,000 specimens, of which 3000 are types mostly from the New World, and will thus, it is claimed, give the United States National Museum a better representation of American species in this group than exists in any other museum. In the same report Dr. Walcott states that during the year the Smithsonian Institution directed or took part in forty scientific expeditions to various parts of the world. Most of these expeditions were for the collection of natural history specimens, and the report emphasises the urgent need for making such collections before more species of animals and plants are extinguished by the rapid encroachments of civilised man. This great activity was rendered possible by the generosity of other organisations and of many private citizens.

Applications are invited for the following appointments, on or before the dates mentioned:—A male assistant horticultural instructor at the Hertfordshire Agricultural Institute, Oaklands, St. Albans—The Clerk of the County Council, 28 Castle Street, Hertford (April 14). A head of the department of pharmacy of the Bradford Technical College—The Principal, Technical College, Bradford (April 23). A lecturer in geography (man or woman) at Bedford College for Women—The Secretary, Bedford College for Women, Regent's Park, N.W.1 (May 14). A teacher of woodwork and metal work at St. Olave's School, Tower Bridge, S.E.1—The Head Master. A sanitary inspector in connexion with the Sudan Medical Service—The Controller, Sudan Government, London Office, Wellington House, Buckingham Gate, S.W.1. Civilian education officers of the Royal Air Force—The Secretary, Air Ministry, Adastral House, Kingsway, W.C.2.

Our Astronomical Column.

Comets.—A later orbit of Stearns's comet, including observations up to Mar. 18, has been computed by Messrs. J. P. Möller and Bengt Strömgren (*Copenhagen Circ.* 144).

$$\begin{aligned} T &= 1927 \text{ Mar. } 1{\cdot}5645 \text{ U.T.} \\ &\left.\begin{aligned} \omega &= 6^\circ\ 57'{\cdot}64 \\ \Omega &= 214\ \ 31{\cdot}64 \\ i &= 87\ \ 8{\cdot}15 \end{aligned}\right\} 1927{\cdot}0 \\ \log q &= 0{\cdot}56575. \end{aligned}$$

The plane of the orbit agrees well with that found by Mr. L. E. Cunningham, but the date of perihelion is six months earlier, so that no increase in light is to be expected. The comet is, however, an easy telescopic object, and should be followed for several months. The following observation was obtained by Dr. A. C. D. Crommelin:

	R.A. 1927·0	S. Decl.
Mar. $27^d\ 0^h\ 48^m\ 39^s$ U.T.	$15^h\ 9^m\ 22^s{\cdot}40$	$1^\circ\ 43'\ 33''{\cdot}2$

The comet was about 1′ in diameter, with distinct central condensation; the position is in good agreement with that calculated from the above orbit, which is probably near the truth. The following are the positions for 0^h calculated from it:

April 5, R.A. $15^h\ 3^m\ 32^s$; N. Decl. 1° 36′; April 13, R.A. $14^h\ 57^m\ 12^s$; N. Decl. 4° 38′.

Mr. G. Merton has found an image of Pons-Winnecke's comet on a plate taken Feb. 25·06804 U.T. R.A. 1927·0, $14^h\ 4^m\ 25^s{\cdot}54$; N. Decl. 23° 49′ 13″·6; magnitude, 15; diameter, 15″. He has also measured a photograph of comet Comas Sola taken by Mr. F. J. Hargreaves and gives the following position:

Mar. 23·8729 U.T.; R.A. 1927·0, $4^h\ 36^m\ 26^s{\cdot}67$; N. Decl. 30° 27′ 43″·5; magnitude, 12·6.

Mercury as an Evening Star.—Herr C. Schoch writes to say that he had many replies to his request for observations of Mercury as an evening star in February (Nature, Feb. 12, p. 252). At Arosa, in Switzerland, it was visible for the first time on Feb. 13, the *arcus visionis* being 10°·2, the same as the value indicated by the old Babylonian observations. The duration of visibility was 62 minutes at Arosa, 66 minutes at Steglitz, the longest duration recorded at Babylon being 72 minutes. He noted the colour of Mercury, seen from Steglitz, as yellow, without admixture of red. Only three reports were received from England, the weather being generally cloudy.

Herr Schoch's latest value of the solar acceleration in a century is 2″·98 if measured by the increase of speed, but 1″·49 if measured by the distance gained, which is the more usual method. He ascribes the acceleration to the lengthening of the day by tidal friction, and gives the formula, length of day = 24^h (reckoned as in 1900) + $0^s{\cdot}00194T$, so that 52,000 years from 1900 will be required to make the day 1 second longer. T denotes the centuries after 1900.

Southern Double Stars.—Mr. W. H. van den Bos, who is observing southern double stars, gives a third list in *Bull. Astron. Instit. Netherlands*, 3, 114, containing 423 new pairs and bringing his total discoveries to 634, of which 50 are nearer than 0·24″, 104 between 0·25″ and 0·54″, and 87 between 0·55″ and 1·04″. Very few are of types *B* and *M*. More than one-third are of type *G*, the order then being *A*, *K*, *F*. ψ Sagittarii is an interesting star. The magnitudes are 5·5, 6·0, separation 0 2″, spectrum *F*5. This has also been observed as a spectroscopic double at the Lick Observatory station at Santiago; both spectra visible, relative velocity 130 km./sec. Mr. van den Bos says "This can hardly relate to the visual pair, unless the eccentricity and inclination are large, the period short, and the spectrograms taken near the node."

Research Items.

Orientation of Churches.—In a lecture on "The Orientation of Churches," recently delivered to the members of the Sidmouth Literary Society, the Rev. John Griffith paid a whole-hearted tribute to the work of Sir Norman Lockyer in the study of stone circles from the astronomical point of view. His attention was first directed to the subject by an article by Sir Norman on "The Agricultural Divisions of the Year" in NATURE, in which it was pointed out that the orientations of stone circles grouped themselves around February, May, August, and November. This 'farmer's year' was based upon a division of the year with which he himself had been familiar from boyhood and, as he had at once pointed out to Sir Norman, coincided with the Celtic divisions of the year of tradition and folklore; while English fairs, as dated at the beginning of the last century, clustered around these four points. These facts indicate a continuous calendrical usage from the present day back to the stone age, over a period of 4000 years. Stimulated by this result of the application of astronomical methods to the study of ancient monuments, Mr. Griffith has devoted himself to investigating the orientation of the older churches of Great Britain and has obtained similar results. He finds that, allowing for a difference of five days in the calendar between the twelfth century, when most of those churches were built, and the present day, there appears to be evidence of dedication to a popular saint, who often differs from the official patron saint. In Wales the choice is generally limited to four saints, Mary, Michael, Peter, and John the Baptist, while everywhere the feast of St. James with St. Philip on Mayday is popular as occupying a seat which, since the dawn of traditional history, has been held by one pagan deity or another.

Rest Periods in New Guinea.—In *Man* for March, Prof C. G. Seligman describes the alternation of rest and work periods among the Sinaugolo of Rigo District, New Guinea. Among this people the *dubu* could be built and the great feast, the *tabu*, be celebrated only during the *kaba* period; while in the period known as *dauka*, intervening between two *tabu* feasts, the drum was not sounded or the customary small feasts held, while only those known as *dauka*, feasts accompanying payment for a wife, and death and mourning feasts, could take place, dancing being to the accompaniment of bamboo dancing sticks and not the drum. Food was not piled on the *dubu* but on temporary platforms. Otherwise life proceeded as usual, and the customary hunting, fishing, planting, and sexual taboos were observed. A *dauka* period recurred every second or third year. According to the explanation of a Sinaugolo headman, these periods were instituted to secure the proper observation of these ceremonies, and a relaxation from the toil of ordinary life represented by the *dauka* period. In the *tabu* feast itself all neighbouring and friendly villages take part, but it is given by one portion of a village or by a clan, though sometimes two clans united for the purpose The preparations involved the collection of stores of food under a taboo. Food for the first ceremony, the *kidua*, is collected from neighbouring villages, this virtually constituting an invitation and acceptance of an invitation to the feast. This food was distributed to the visitors from neighbouring villages in the *kidua* ceremony. On the next day the pigs given at the *baiseno*, a dance preceding the *tabu* feast by about a month, were hung to the *dubu*. Then follows the giving away of the *tabu*, an essential feature of which was the boasting of the men with the object of instigating visitors to undertake the next *tabu*. For the next two or three days feasting follows, in which the pigs given at the *baiseno* are killed and eaten.

Early Chinese Cartography.—The oldest two maps of China known to exist were found some years ago at Hsianfu, the capital of the Shensi province, and were described by Prof. E. Chavannes in 1903. These maps formed the subject of a lecture by Prof. W. E. Soothill to the Royal Geographical Society on Mar. 14. They are engraved on stone, and preserved among other stone tablets. Chavannes dated the earlier of these maps 1043, but it is less easy to decide the date of the map from which much of it was copied. Prof. Soothill's conclusion is that the larger map is part of Chia Tan's map completed in A.D. 801, and that it may have been based on P'ei Hsiu's maps of the third century, not directly, but rather on copies elaborated by local cartographers. He believes that, with some change in names, it may be taken to represent China as it was known in the eighth century. The second map would appear to be more recent. It lacks the marginal notes of the other, and is covered by a grid of 100 li squares. Prof. Soothill thinks that it was drawn by an unknown cartographer some time during the three centuries preceding A.D. 1100, that is, after the time of Chia Tan. It suggests an endeavour to reconstruct P'ei Hsiu's lost map, using his net system, but it shows an advance in accuracy from Chia Tan's time.

Eskimo in East Greenland.—In a lecture to the Royal Geographical Society on Mar. 21 on the Cambridge expedition which he led to East Greenland last summer, Mr. J. M. Wordie referred to the traces of former Eskimo habitation which occur on that coast. A search of the coast region between Sabine Island and Scoresby Sound revealed a number of tent rings, groups of winter huts, and a few graves. Clavering Island is rich in remains: some regions, on the other hand, showed no traces. The conclusion is that the Eskimo can never have been very numerous on the east coast, and Mr. Wordie believes that the evidence points to only one period of immigration during which the Eskimo arrived by the north of Greenland. This is a reversion to the earlier views of H. P. Steensby, who held that the Eskimo followed the musk-ox by that route. Recent examination of the north coast of Greenland by K. Rasmussen renders that route unlikely, not merely in the lack of Eskimo remains but in the absence of game or possible hunting grounds and the bad travelling conditions. Mr. Wordie visited the new Eskimo settlements formed by the Danish Government on Scoresby Sound, which are composed of Eskimo of pure stock from Angmagsalik, the one surviving Eskimo settlement from the original colonisation of that coast. If game resources last, the prospects of these new colonies are good, but it must be remembered that the disappearance of the majority of the east-coast Eskimo during the nineteenth century was probably due to the exhaustion of resources. The same might occur again.

Fishery Investigations at Cullercoats.—The results of the investigations carried out at the Dove Marine Laboratory, Cullercoats, during the year ending June 30, 1926, are given in Report 15 (N.S.), which has recently been issued by the Laboratory. Mr. Storrow and Mrs. Cowan deal with their observations of the length, age, growth, and sexual condition of some 4600 herrings from commercial landings from the Shetlands, Firth of Forth, East Anglia, north-west and south of Ireland. Irish Sea, and Clyde. Mr. Gill, biochemist at the laboratory, gives a preliminary description of some investigations regarding the characterisation of the flesh protein of the herring, the subject being attacked from the point of view of the amino-acids present. Mr. Gill also reports on his estimations of the quantity of dissolved oxygen in the waters of the River Tyne. The percentage in the tidal region follows very closely the amount of fresh water coming down the river, both being at a maximum in the winter and at a minimum in the summer. Heavy rains, however, even for a few days, can raise the oxygen content of the estuary from its low summer values to the high winter values. Mrs. Cowan describes the growth under aquarium conditions of the lumpsucker (*Cyclopterus lumpus*) reared from the egg. Prof. Meek deals with some interesting replies to a letter circulated among fishermen and fishery officers requesting their opinions on the currents along the east coast of Great Britain.

VARIATION IN EARWIGS.—The bimodality of the curve for forceps-length in male earwigs (Forficula) has been well known since the original observations of Bateson and Brindley in 1892. Diakonov in 1925 published further evidence, from material collected in Russia, that the forceps are dimorphic and that the difference is probably not a genetic one but represents two independent positions of equilibrium for forceps development. He also showed various relationships between forceps-length and body-size, but the data were not fully analysed. Prof. J. S. Huxley (*Jour. of Genetics*, vol. 17, No 3) has now published the original measurements and added a further analysis of this apparently unique type of dimorphism. He finds that plotting the logarithm of forceps-length against the logarithm of body-length gives a straight line, indicating that this organ has the same growth-mechanism as other organs showing heterogonic growth With increasing body-size there is a tendency for the forceps to shift from short to long, the forceps of the largest animals always coming in the long group. In a colony under unfavourable conditions there was a decrease of mean body-size, but the means of forceps-length were scarcely affected. Nevertheless, the percentage of individuals in the population with short forceps was considerably increased. Similarly, more favourable conditions shift the forceps-length of some individuals during their development from the short to the long type. But there is still no evidence as to why there should be two positions of stability in forceps-length with a gap between them. This can probably only be determined by experiment.

MICRO-ORGANISMS IN TICKS.—Part I. of the 11th and 12th Reports of the Director (Sir Arnold Theiler) of Veterinary Education and Research of the Union of South Africa (Pretoria, Sept. 1926, 817 pp.) contains twenty-six papers ranging over the varied work of this active Department—serological investigations and other studies on blood and on inoculation, protozoology, helminthology, entomology, and studies on grasses and other plants. Attention may be directed to the account, by Dr. E. V. Cowdry, of a group of micro-organisms transmitted hereditarily in ticks and apparently unassociated with disease. These organisms are pleomorphic, bacterium-like, and intracellular, and they stain much less intensely with ordinary methods than most bacteria. They were found in fifteen different species of ticks, including representatives of the Argasidæ as well as the Ixodidæ. No evidence could be found of injury to the tissues of the ticks other than physical distention of the cells to accommodate large numbers of the organisms. They were found in every tick examined, not only from South Africa but also from Jamaica, Trinidad, Honolulu, and several parts of the United States; and as they were present in the eggs of ten species and in the unfed larvæ of seven species, it was concluded that transmission was hereditary. The organisms in several respects resembled Rickettsia, but were of larger size. They also resembled the symbionts of certain lice and blood-feeding flies, but they never gave rise to definite organ-like structures comparable with the mycetomes, and they were restricted to the Malpighian tubes and the eggs, whereas the symbionts referred to are confined to the digestive tract.

THE UTILISATION OF POLLEN BY THE HONEYBEE.—In a paper entitled "The Collection and Utilisation of Pollen by the Honeybee," published as Memoir 98 (June 1926) of the Cornell University Agricultural Experiment Station, Mr. Ralph L. Parker contributes observations of considerable interest. Pollen is known to be the chief source of protein in the food of bees, and a lack of it reacts deleteriously upon the developing brood. The adult bees use the nitrogenous material of pollen in the elaboration of the brood food that is fed to the larvæ for the first two days after eclosion from the egg. This predigested food is fed to the queen all through her larval life. The worker and drone larvæ, on the other hand, are fed afterwards with a mixture of honey and undigested pollen. Substitutes for pollen such as rye, oats, corn, pea-meal, etc., were not found to be beneficial. The feeding with such substitutes is a failure, since, although it may stimulate egg-laying by the queen and brood-care by the workers, larval development is not completed. Some of the simple sugars and proteins of pollen are available to the bee, but most of the other contents are not available. Proteolytic enzymes have been shown to be present in the bee's alimentary canal, but the actual proteins of pollen utilised by that insect have not, so far, been identified. Bee-keepers in regions which at times experience a shortage of pollen during the beginning of the season, are advised to preserve combs of pollen for use during such an eventuality, since no efficient substitutes can be recommended.

ORE DRESSING IN CANADA.—The Annual Report of Investigations in Ore Dressing and Metallurgy for 1925 by the Mines Branch of the Canadian Department of Mines has just been published and shows evidence of very active work. A number of complex ores, *e.g.* silver-lead-zinc, gold-copper, copper-lead-zinc, etc., have been investigated, and satisfactory methods for the treatment of the ores have in most cases been devised. A new process is outlined for the treatment of ilmenite, producing a titanium oxide concentrate capable of being used for the production of pigment and other purposes. Detailed reports upon the concentration by flotation of Canadian molybdenite and graphite ores are also included. It is evident that this section of the Department of Mines is doing excellent service in the development of the Canadian mining industry.

THE PALAGONITE FORMATION OF ICELAND.—The first of a series of papers describing a comprehensive study of the Icelandic eruptives (based on a collection made in 1924 by Dr. G. W. Tyrrell and Dr. M. A. Peacock) appears in the *Trans. Roy. Soc Edin.*, vol. 55, Pt. 1, No. 3, 1926. It consists of a preface to the series, followed by an account of the basic tuffs by Dr. Peacock. These are either sideromelan-tuffs or palagonite-tuffs. The former consist of basalt glass which has been drastically chilled and fragmented owing to the sub-glacial extrusion of basalt magma. The palagonite-tuffs are the older sideromelan-tuffs which have been hydrated, usually by submersion beneath the sea or by hot springs. It is shown that palagonite is essentially the hydrogel of sideromelan, the hydration being accompanied by a partial loss of lime and soda and an almost complete oxidation of iron. The palagonite due to submersion is an isotropic yellow gel, but in that due to the action of hot springs there is an obscurely birefringent fibrous structure. Both types are unstable and tend to crystallise with loss of part of the water into chlorites and zeolites. It is suggested that Fermor's proposal to use the term *palagonite* for chlorophæite and other late-magmatic hydrous residual materials in basaltic rocks should be discontinued, since the latter, though of somewhat similar composition to that of the Iceland palagonite, have originated by an entirely different process.

The Composition of Meteorites.—In the *Proc. Amer. Phil. Soc.*, vol. 65, No. 2, p. 119, G. P. Merrill summarises recent work on the chemical and mineral composition of meteorites. The chief point of interest is the result of a series of carefully conducted analyses of representative masses. Twenty-eight terrestrial elements have so far been detected, among those not found being antimony, arsenic, barium, strontium, fluorine, lithium, tin, lead, zinc, and gold. This is a particularly significant list, for it includes many of the common ore- and gangue-making elements that are associated with the continental rocks of the earth. The characteristic ore-making elements of norites and peridotites, such as copper, cobalt, nickel, and the platinum group, are all present, as would be expected. The minerals of meteorites are in many cases of a type that can be accounted for, provided that oxygen was relatively deficient in the medium from which they crystallised. It is pointed out that nothing akin to rocks of the granite family has been found in meteorites; and further, that meteorites have never been found in terrestrial beds of any geological horizon but the most recent. Merrill regards the possible meteoric origin of tektites as still unproved.

Coal Carbonisation.—On Feb. 8, 1927, Dr. C. H. Lander, Director of the Fuel Research Board, read a paper before the Institution of Petroleum Technologists on "The Production of Oil from Coal." The history and work of the Fuel Research Department, which set out to study this problem in particular, was surveyed. The most interesting part was a disclosure of recent experience with vertical retorts of cast iron. Coal has been carbonised at 625° continuously in this retort setting, from March to December 1926, when it was let down for inspection. These retorts, which are again in use, are stated to have been easy to operate, and the coke product has given satisfaction to consumers. Yields of tar reaching 18 gal./ton were obtained, and it is believed that the retorts approach technical success More experience of protracted working is necessary before commercial success can be assessed.

Irregular Emission of X-Rays.—Any experimental work with X-rays in which unusual discontinuities are recorded is now of particular interest, in view of its possible bearing on the *J*-phenomena which are being investigated by Prof. Barkla and his school. It has already been shown that in certain circumstances the relation between the intensity of a number of characteristic rays and the voltage on the bulb changes abruptly at about 4·5 times the minimum potential required for the excitation of each. D. Nasledow and P. Scharawsky, working in the X-ray Institute at Kiew, now report similar changes when a Muller tube of the hot filament type is run at constant voltage and with a variable current (*Zeit. für Phys.*, **41**, p. 155, 1927). The $K\alpha$ and $K\beta$ lines from a copper target were separated by reflection from calcite, and their intensities were measured by an ionisation method. When less than 4 milliamperes were passing through the bulb, the intensity of either line was closely proportional to the current; for greater currents the rate of increase was linear, but less rapid than before. A break still took place at 4 milliamp., when the exciting peak voltage was raised from 30 kilovolts to 45 kilovolts. No explanation is offered of these results—which the authors propose to extend—but the apparatus appears to be described in sufficient detail to permit of comparison with the experience of other workers in this field.

Forms of Sulphur Trioxide.—The *Gazzetta Chimica Italiana* for Jan. 1927 contains a series of memoirs by G. Oddo and A. Casalino on the different forms of sulphur trioxide, which were studied some years ago by Oddo. The vapour density of the liquid form at 25° is only slightly above the value for SO_3, although slight association may be present. The amorphous and fibrous solid varieties gave molecular weights about 83·77 as a mean. The solutions of the trioxide in phosphoryl chloride were found to give solid solutions in all proportions, and the results of the depression of freezing-point were therefore irregular and unsuitable for the determination of the molecular weight. In anhydrous sulphuric acid the molecular weight of the liquid form was 80, of the fibrous form 88. The papers contain a detailed description of the preparation of the different forms of sulphur trioxide and of the transformation of one form into another.

Magnetic Observations in Australia.—Magnetic observatories in the southern hemisphere are so few that it is an event of some importance when a new one is instituted. For many years, only one magnetic observatory was in operation in Australia, at Melbourne, and even this was of limited service to magnetic science owing to the non-publication of its observations. Gradually this observatory became disturbed by electric tramways, and in 1919 a new observatory, 34 miles away, was built. The magnetograph house is above ground, and consists of a chamber within a chamber, the walls being well lagged to reduce temperature changes. No attempt is made to control the temperature of the inner room by artificial heating. There is no resident observer, the records being changed by a local resident, who also registers a time-break at the beginning and end of each record. The records are posted weekly to Melbourne for development and computation; an observatory official visits the station monthly to make absolute observations for base-line values, and to execute any necessary adjustments. The magnetographs are of the Eschenhagen type; the absolute instruments include a Kew magnetometer and a Schultz earth inductor. During 1924, which appears to be the first year for which hourly observations are published, the vertical force instrument gave considerable trouble, there being large changes in scale value and base line; the horizontal force magnetograph had a nearly constant scale value. The results are given in an (undated) publication, "Melbourne Observatory: Hourly values of the magnetic elements at Toolangi in 1924." It is very satisfactory that the Director, Dr. J. M. Baldwin, has been able both to institute this new observatory and also to obtain publication of hourly values of the elements, a course which places the observations so fully at the disposal of investigators of terrestrial magnetism. It is to be hoped that in time the Government of Victoria may provide the funds necessary for a resident observer, without which it is impossible to maintain a magnetic observatory with full efficiency. The only other magnetic observatory in Australia is the one recently instituted by the Department of Terrestrial Magnetism of the Carnegie Institution of Washington; it is situated near Perth, Western Australia.

The Botany School of the University of Sydney.

THE opening of the new Botany School in the University of Sydney is an event not only important for the British Empire, but also for the world at large. The building is in modernised perpendicular Gothic and harmonises with the main structure of the University of Sydney, which presents some interesting resemblances both in its architecture and its origin to the well-known main building of the University of Toronto. The construction is in stone, and the building is so arranged that it will be an ornament to the University for many years. Although architecturally attractive, it does not represent the petrification of the science in the Pierian springs of architecture rightly dreaded by Thomas Huxley, for it is thoroughly well lighted, spacious, and in every way practical. The entrance is adorned by representations of some of the great masters in the science. The idea of commemorating the great, however, is not confined to the exterior of the building, for the laboratories and other work-rooms are named after distinguished botanists. The botanical museum bears the names of Bentham and Hooker, and its windows show the portraits of such outstanding botanists as Hofmeister, Grew, Sachs, Nageli, Hooker, Bentham, and others. The herbarium, which is spacious and well equipped, is named after John Ray, and in its windows appear effigies of Morrison, Ray, Tournefort, De Jussieu, Linnæus, Robert Brown, etc. The advanced laboratory is named after Charles Darwin. The research laboratory bears the name of Robert Brown, while the first-year laboratory is named after Sir Joseph Banks, two names so signally connected with the beginnings of Australian botany.

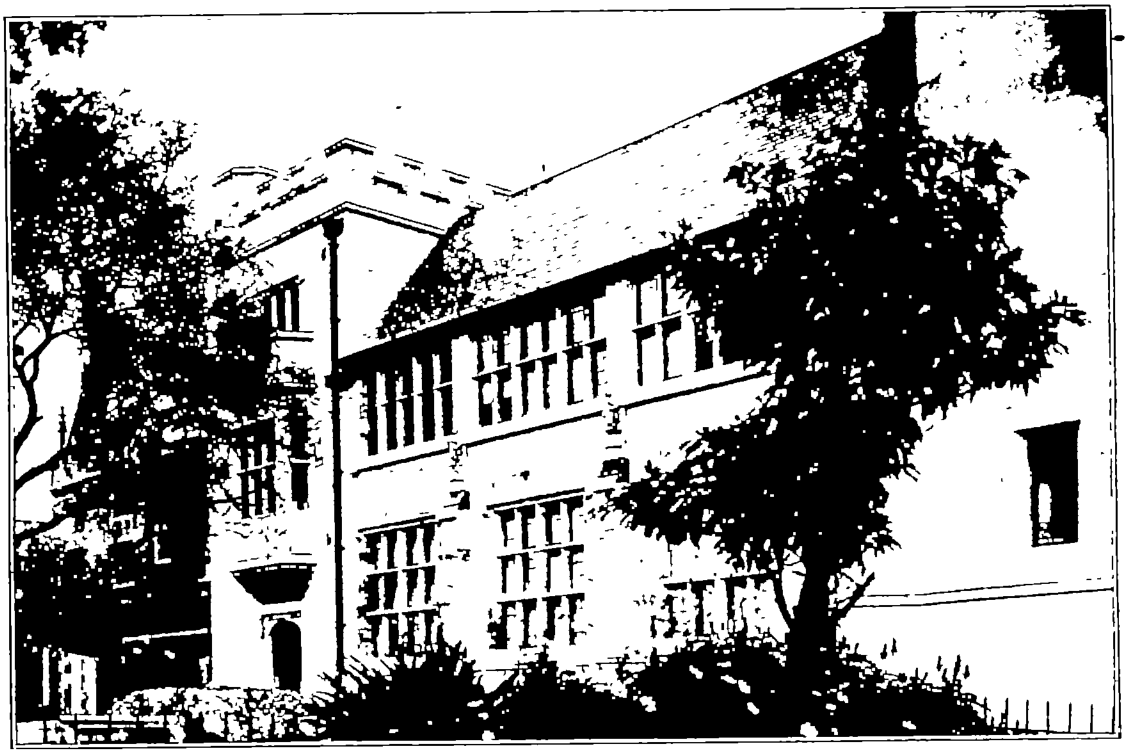

Fig. 1.—Botany School of the University of Sydney, N.S W.

The library and reading-rooms provide abundance of space, but the shelves are as yet meagrely lined with books. It is hoped that this shortcoming may, before long, be remedied in view of the great interest which the public in Sydney has begun to take in botanical science.

A physiological laboratory is also among the rooms in the Botany School, and it supplies excellent facilities for the prosecution of that important side of the science. Numerous research rooms for the staff and advanced students are included in the plan of the building, and last, but not least, the lecture theatre is capable of seating two hundred students.

The building was formally opened on Nov. 6, 1926, in the presence of the Governor of New South Wales, the Vice-Chancellor of the University, and Prof. Anstruther Lawson, the head of the school. Prof. E. C. Jeffrey, of Harvard University, was present as guest of honour to deliver an address and also the formal felicitations of this University.

The opening of the new Botany School in Sydney University is a scientific event of the first magnitude, because it supplies an equipment in the southern hemisphere in every way adequate for the carrying on of botanical investigation. The facilities provided by the Botany School, in fact, compare most favourably with those which are offered by the larger universities in the northern hemisphere. In his remarks Prof. Jeffrey referred to the great advantages which Australasia presents to the students of plants, combining as it does a great variety of environment with healthful conditions of existence and a stable and well-organised government. Australasia, in fact, unites to a large extent the advantages of the tropics with the comfort and salubrity of temperate regions. The flora of Australia is quite as interesting as its fauna, but not nearly so well known. It was suggested, further, that it would be a great advantage if every student of botany in the northern hemisphere could some time or other visit Australasia. Prof Lawson, in the name of the University, offered the full hospitality of the botanical laboratory to visiting botanists.

The Botany School of the University of Sydney is a monument to the zeal, capacity, and artistic sense of Prof. Anstruther Lawson. The school has already a large and growing body of students and a highly creditable list of published researches.

E C. J.

Animal Breeding Research Department, University of Edinburgh.

We have received from the Director, Dr. F. A. E. Crew, the sixth annual report of the Animal Breeding Research Department of the University of Edinburgh. This department has recently received two large benefactions, namely, £10,000 from Lord Woolavington toward a fund for converting the directorship into a University chair, and £30,000 for general purposes from the Rockefeller Fund, so that the Department has the happy prospect of enlarging the scope of its work.

The report before us contains the list of a large number of problems of inheritance which are being attacked, but the progress made with the solution of any of them seems to be but moderate. 'All of them will require a long stretch of years before any considerable advance is made towards their solution, and in the case of domestic animals, the numbers with which it is possible to deal are too small to justify a successful analysis into Mendelian 'factors.'

More striking results are obtained from the investigation of endocrine reactions. We may direct attention to some extremely interesting results of extirpation of gonads in the mouse obtained by Mr. Kasur. The weight of the male remains unchanged, that of the female increases, but the kidney of the normal male is much heavier than that of the normal female, whereas the thymus and spleen of the former are considerably lighter than those of the latter After castration the kidney of the male decreases whilst the thymus and spleen increase in weight, so that in all these respects the animal approaches the female type.

Another thought-provoking result was obtained by Mr. A. W. Greenwood acting in collaboration with the Director. He grafted into the body of a female chick four days old, after removing her ovaries, the testes of her brother. The bird assumed the plumage of the cock. This is in accordance with Zawadovsky's interesting results, in which he converted a cock into a hen and vice versa by the transposition of the gonads. But in the case under consideration the bird, after a subsequent moult, reverted to the plumage of the hen. A post-mortem examination revealed the fact that a small fragment of the functional left ovary had been left in the body by the operation, but that this remnant had degenerated. Not only, however, had the testis grafts survived and produced an abundance of testicular tissue, but ovariotomy had stimulated the vestigial right ovary to activity and it had also produced testicular tissue, so that the bird was in fact over-masculinised. Messrs. Greenwood and Crew advance the hypothesis that the ovary exercises a heavier drain on metabolism than the testis, and that the distinction between male and female secondary sexual characters is due to the degree of strain exercised on the organisation by the respective gonad in each case. If the testis is artificially increased in bulk beyond the normal, it exercises a strain equal to that of the ovary, and hence the secondary sexual characters of the female are produced.

E. W. M.

Experiments on Molecular Complexity.

Prof. H. Brereton Baker, for his presidential address at the annual general meeting of the Chemical Society on Mar. 24, chose as his theme "Experiments on Molecular Complexity." He had claimed that, like Sir Isaac Newton, "hypotheses non fingo," but, speaking later at the anniversary dinner, admitted that he was an inveterate maker of hypotheses, which, however, he forbore to publish.

The investigations described in the address arose out of the observation, some five years ago, that if liquids of very varying types were subjected to prolonged drying, the boiling points were raised to a very considerable extent. This rise, ascribed to an increase in the complexity of the molecules, takes place with typically unassociated liquids; hence it may be that all liquids are capable of association. Since water can also promote dissociation, it is conceivable that its absence might influence the molecular complexity in opposite directions; so far, however, dry liquids boiling at subnormal temperatures have not been obtained, although dry benzene has been separated into fractions boiling at 80° and 118° respectively. Further researches were carried out to see if catalysts other than water are effective, the experimental methods involving measurements of vapour density and surface tension.

Preliminary experiments in barometer tubes with very pure sugar charcoal gave definitely positive, although not quantitatively reproducible, results. For example, the vapour pressure of ethyl ether at 16° was raised by 25 mm., of methyl alcohol at 35° by 12 mm., and of benzene at 23° or 37° by 2 mm. Prolonged experiments with Smith and Menzies' methods still gave variable results—a circumstance which has led Prof. Baker to two somewhat important deductions. First, a catalyst evidently acts very slowly, and sometimes in a direction contrary to that shown in the final equilibrium; secondly, a pure liquid appears to have no constancy of composition, but possesses a vapour pressure which depends on the history of the specimen. It therefore became necessary to employ a method by which the vapour pressure of the liquid could be balanced against that of the liquid with the catalyst.

Such a method made use of a U-tube containing mercury, the horizontal upper ends each carrying a pair of bulbs, and being connected by a capillary tube. The liquid could thus be distilled on to a catalyst, the capillary junction closed, and the difference arising between the vapour pressure of the pure liquid and that in contact with the catalyst could be directly measured. Acetic acid, benzene, methyl alcohol, ether, and bromine were examined, the catalysts being charcoal, platinum black, or thoria In every case the catalyst caused an increase in the vapour pressure of the liquid; such a difference was, indeed, clearly apparent in a sample tube exhibited. An even more striking exhibit was a two-limbed tube in which, three weeks previously, accurately measured equal volumes of bromine had been placed, one of the limbs also containing charcoal. After evacuation, the tube had been sealed; so much bromine had afterwards distilled from the limb containing the catalyst that the charcoal was left almost dry. A refinement of the barometer tube method showed that the difference was increased by heating and diminished by cooling; heating and afterwards cooling to 20° always caused an increase in vapour pressure, and cooling the reverse, the original value for a particular catalyst being restored only after some weeks.

For the surface tension measurements Ramsay and Shields' method was employed, the diameters of the specially resistant capillary tubes being determined directly to one-thousandth part of a millimetre. Comparison tubes were, of course, always used. It was noteworthy that the pure liquid, for example, acetic acid, does not reach its normal value until three weeks after filling the tube, the process of boiling to remove air clearly causing dissociation. Thus, after 2 days the molecular weight was 1·568 × 60, and after 3 weeks or 9 months, 2·097 × 60. Heating for a short period in most cases increased the molecular complexity, whilst heating for a long period decreased it. The catalyst, which gave a molecular weight value for acetic acid (measured after 3 weeks) of 2·525 × 60, did not immediately produce its maximum effect on the complexity of the molecules.

Prof. Baker considers that all liquids may be regarded as analogous to a dissociable gas such as nitrogen tetroxide, the processes of association and dissociation, however, being much slower for liquids than for gases. The effect of the presence of solid catalysts, as would be expected, is much slower for the liquid than for the gaseous condition, and it is difficult to understand how their special influence is exerted. The president acknowledged the help given to him by his assistant, Miss Margaret Carlton, who has done a considerable portion of the experimental work.

University and Educational Intelligence.

EDINBURGH.—Mr. V. Gordon Childe has been appointed by the University Court as the first occupant of the Abercromby chair of archæology. This chair was founded in 1925 in accordance with a provision for its endowment in the will of the late Lord Abercromby, the well-known archæologist and authority on the pottery of the bronze age in Britain. Mr. Childe was educated at the University of Sydney, where, after taking his M.A. degree, he was awarded a classical scholarship tenable at Oxford. He became a member of Queen's College, Oxford, in 1914, took his B.Litt. in 1916, and a first class in the honours school of *Literæ Humaniores* in 1917. After a short period spent in Australia, Mr. Childe returned to England, and since then has been engaged in archæological research and has acted as librarian of the Royal Anthropological Institute. He has published a number of papers in archæological periodicals and two books of great erudition and originality in the History of Civilisation Series—"The Dawn of European Civilisation" and "The Aryans."

LEEDS.—The Miners' Welfare Committee has offered a contribution of £10,000 towards the cost of erection of a new building for the Mining Department of the University. This shares with the Department of Coal Gas and Fuel Industries a building which was erected in 1906, but now, owing to the growth of both departments, it has become inadequate. The Department has received loyal support from the industry. Since 1899 the West Yorkshire Coal Owners' Association has made an annual grant, and has recently contributed £25,000 to the University Development Fund, while contributions from individual members of the mining industry amount to more than £2500. The support thus given by the industry may not improbably result in the Mining Department being the first part of the building scheme to be undertaken.

LONDON.—Mr. W. E. Le Gros Clark has been appointed as from Sept. 1 to the University chair of anatomy tenable at St. Bartholomew's Hospital Medical College. In 1924 Mr. Clark was awarded the Hunterian Medal for anatomical research, and was elected a member of the Board of Examiners for the Fellowship of the Royal College of Surgeons. He has published numerous contributions on the skulls of primates in the *Proceedings of the Zoological Society*, *Journal of Anatomy*, and similar publications.

Dr. Hamilton Hartridge has been appointed as from Sept. 1 to the University chair of physiology tenable at St. Bartholomew's Hospital Medical College. Dr. Hartridge has been a fellow of King's College, Cambridge, since 1912, and was awarded the Horton Smith Prize in 1918. Since 1919 he has been lecturer on organs of special sense and senior demonstrator in physiology at the Physiology Laboratories, Cambridge. He has published numerous papers in *Proceedings of the Royal Society*, 1922–25, *Philosophical Magazine*, 1923, and the *Proceedings of the Cambridge Philosophical Society*.

The following Doctorates have been conferred: D.Sc. in statistics on Mr. A. E. R. Church (University College), for a thesis entitled "On the Means and Squared Standard Deviations of small Samples from any Population"; D.Sc. in physics on Dr. R. C. Johnson, for a thesis entitled "The Structure and Origin of the Swan Band Spectrum of Carbon," and other papers.

OXFORD.—The Delegacy for Extra-Mural Studies has arranged a special course of zoology, primarily for teachers of science in secondary schools, on Aug. 2-12. The course, which is part of the annual summer meeting organised by the Delegacy, will deal mainly with recent developments in zoology. Further particulars and application forms can be obtained from the Rev. F. E. Hutchinson, Acland House, Broad Street, Oxford.

THE annual value of the Beit memorial fellowships for medical research has been increased and will take effect as from October 1 next. An election of junior fellows will take place in July next. Applications upon a prescribed form must be sent on or before June 1 to Sir James K. Fowler, Honorary Secretary, Beit Memorial Fellowships for Medical Research, 35 Clarges Street, W.1.

THE Air Council has decided to increase the number of prize cadetships in the Royal Air Force offered for competition annually from three to twelve. These cadetships enable boys to complete the two years' course at the R.A.F. Cadet College, Cranwell, at a cost of only £40 in all to their parents. Candidates are selected at an examination held by the Civil Service Commission in June and November; they must be between 17½ and 19½ years of age, and must be in possession of School Certificate A or B. Applications for the June examination must reach the Civil Service Commission on or before May 4. Further information can be obtained on application to the Secretary, Air Ministry, London. W.C.2.

THE list of "Students from other Countries in the Universities and University Colleges of Great Britain and Ireland in October 1926," issued by the Universities Bureau of the British Empire (50 Russell Square, London, W.C.1), contains more than its title suggests. It is a register of the names of students from other countries attending each institution of university rank, and may appear, therefore, to have either the virtues or vices of a public card-index according to the purpose or predilection of the person seeking the type of information afforded by a list of actual names. It is to be noted, however, that on one page the number of students from each country is set out. The following extracts from that page may not be without significance: Africa, 1054; America, 824; Asia, 1754; Europe, 643; The Pacific, 321.

Calendar of Discovery and Invention.

April 3, 1449.—In the Patent Roll, 27 Henry VI., Part 2, No. 468, is the grant of letters patent, dated April 3, 1449, to John of Utynam, born in Flanders, for the exclusive right of making coloured glass for twenty years. This is the earliest known example of an industrial monopoly patent in England or elsewhere. John came to England at the King's command to make glass for Eton College and St. Mary and St. Nicholas College, Cambridge, and because the said art had never been used in England and John intended to instruct divers lieges of the King in many other arts never used in the realm, the King granted that no liege of the King learned in such arts was to use them for a term of twenty years against the will and consent of John under a penalty of £200.

April 4, 1879.—During the course of his lectures at Birkbeck College, Chaloner remarked, "The man who eliminates phosphorus by means of the Bessemer converter will make his fortune." This chance remark fixed itself in the mind of Sidney Gilchrist Thomas, the police-court clerk, who after some years' experiments solved the problem, and in 1877 and 1878 took out patents for the manufacture of 'basic' steel. He was assisted by several metallurgists, but it was Windsor Richards who on April 4, 1879, made the first successful experiments on a large scale, these being carried out at the works of Bolckow, Vaughan, and Co., Middlesbrough. Thomas reaped a fortune, but died at the early age of thirty-five years and was buried in the Passy Cemetery, Paris.

April 5, 1864.—An important improvement in photography was announced by Swan in his paper on the new carbon process read to the Photographic Society on April 5, 1864. Swan employed a tissue "as pliant as paper, and as transparent and smooth as glass, formed of collodion on the one side, and of gelatine impregnated with ammonium bichromate, carbon (indian ink) and saccharine matter (sugar) on the other." Swan's process was at once adopted, notably in France, and to it we owe the finest reproductions of famous pictures.

April 6, 1911.—Leaving New York in the *Roosevelt* in July 1908, Peary again set out for the Arctic, and on April 6, 1911, reached the North Pole, "the crowning result of twenty-three years' devotion to Arctic exploration."

April 7, 1795.—Before the Revolution there was no uniformity in French weights and measures. On May 8, 1790, the Constituent Assembly therefore charged the Paris Academy of Sciences with the organisation of a better system. Lagrange, Laplace, Cassini, Mechain, Lavoisier, Delambre, Prony, and others took part in the work, but it was the measurement of an arc of the meridian from Dunkirk to Barcelona by Delambre and Mechain which led to the adoption of the metre—$\frac{1}{10,000,000}$th part of the distance from pole to equator—as the standard of length, this important unit being made legal on April 7, 1795. The whole metric system of weights and measures was completed in 1799, and was made the only legal one on Nov. 2, 1801.

April 8, 1838.—Regular trans-Atlantic steam navigation was inaugurated by the s.s. *Great Western*, which left Bristol for New York on April 8, 1838. She was a fine wooden paddle-wheel vessel, especially designed by Brunel for this traffic, and was the most remarkable ship of her day. Other steam vessels such as the *Savannah*, H.M.S. *Rhadamanthus*, *Curacoa*, and *Royal William* had crossed the Atlantic before, but were quite unsuitable for continuous steaming, while the first Cunarder, the *Britannia*, did not begin running until 1840. E. C. S.

Societies and Academies.

London.

Royal Society, Mar. 24.—**Sybil Cooper, D. E. Denny-Brown, and Sir Charles S. Sherrington**: Interaction between ipsilateral spinal reflexes acting on the flexor muscles of the hind-limb. The contraction evoked by reflexes exciting the same muscle when they are concurrent falls largely below the sum of the individual effects which they exert when apart. The effect of one of a pair of concurrent reflexes may default totally, *i.e.* be totally occluded. Such 'occluding' interaction is quite different from the inhibitory interaction of 'antagonistic' reflexes. Its explanation seems to be that, at some structure impinged upon in common by the 'allied' reflexes, (1) tetanic activation from one source precludes concurrent activation by a second, and (2) is not disturbed by the convergent activity of a second. The occlusion is a measure of the convergent overlap of 'allied' reflexes upon 'motor units' held in common. The occluded contraction emerges from occlusion without pause and step for step as the occluding activation subsides. Each individual afferent excites a reflex contraction which is of a pattern specific to that particular afferent.

R. J. Ludford: The Golgi apparatus in the cells of tissue cultures. The Golgi apparatus in the cells of tissue cultures undergoes a change in form with the spreading out of the cells on the surface of the cover-glass. It may be stretched until it fragments and its individual particles become dispersed in the cytoplasm; in other cells the osmophil substance of the Golgi apparatus becomes spread in the form of rodlets and granules upon a less deeply impregnated material (the idiosome, or sphere substance), and both substances become scattered together in the cytoplasm. Certain of the fatty globules in the cells of tissue cultures are considered to arise in relationship with the Golgi apparatus.

C. E. Walker and Margaret Allen: The nature of Golgi bodies and other cytoplasmic structures appearing in fixed material. If lecithin and kephalin are added to colloidal mixtures and films or drops fixed without using acetic acid, structures exactly resembling Golgi elements, etc., are produced. Mitochondria, etc., are also represented. These structures also do not appear if acetic acid is used in the fixative. These artificial structures behave in the same way as Golgi apparatus, etc., when treated with osmic acid and when washed with turpentine. On adding oleaginous emulsions to the colloidal mixtures the structures produced by fixation and osmication appear to behave in a similar manner in relation to the globules of the emulsion as do Golgi elements, etc., to the nucleus of the cell.

W. S. Patton and E. Hindle: The development of Chinese leishmania in *Phlebotomus major* var. *Chinensis* and *P. sergenti*, var. (See Nature, Mar. 26, p. 460.)

G. S. Sansom. The giant cells in the placenta of the rabbit. Two kinds of giant cells are found in the uterus. The larger are derived from the fœtal trophoblast. They rapidly attain an enormous size, persist until about the 22nd day, and then break up into smaller bodies. Large numbers of these cells are also formed from a portion of the trophoblast which projects free into the uterine cavity after the attachment of the blastocyst to the placental folds on the 8th day. The cells proliferated from this 'trophoblastic fringe' pass into the uterine cavity and penetrate the regenerated uterine epithelium. The mesometrial giant cells are of maternal origin. Appearing about the 11th day and persisting until after the 27th day, they never attain great size. The trophoblast of the chorion læve gives origin to great numbers of multinucleate spheres, which become free, and are inactive degenerate structures.

Linnean Society, Feb. 17.—Miss Eleanor **Vachell**: An unusual specimen of Anagallis. The plant was noticed in a newly constructed public park at Coldknap, Barry, Glamorgan, in July 1926. It had eleven stems—seven bearing scarlet flowers and four bearing blue flowers. Two types, *A. arvensis* Linn. and *A. fœmina* Mill., are apparently represented on the same plant.—Julian S. **Huxley**: On the relation between egg-weight and body-weight in birds. The lysis of Heinroth's data on the body-weight and eight of 432 species of birds reveals certain s not brought out in his paper. For birds as a , the relative egg-weight decreases from 12·2 3 per cent. of body-weight as we pass from the of lowest to that of highest body-weight. The tion between egg-weight (y) and body-weight (x) n best be expressed by an equation of the form $y = bx^k$, in which b is constant, but k gradually decreases with increasing body-weight. The limiting value of k appears to be 1·0 for low body-weights. The differences in relative egg-weight between different groups remain approximately constant throughout; but in the smaller members of a group of high mean body-size, relative egg-weight is increasing much more rapidly with increasing body-size than in birds of the same absolute size constituting the heavier members of a group of small mean body-size.—J. T. **Cunningham**: Natural ambicoloration and the production of pigment in flat-fishes. The coloration of the lower side in naturally ambicolorate specimens is not due to the action of light, but seems to be rather a mutation arising from some abnormal condition in the gametes and fertilised eggs.

EDINBURGH.

Royal Society, Mar. 14.—J. H. **Ashworth**: Distribution of anopheline mosquitoes in Scotland. Three species occur, as in England, namely, *A. maculipennis*, *A. bifurcatus*, and *A. plumbeus*. The first is known from only four localities in Scotland, *A. bifurcatus* from 36 localities—this being apparently the most abundant and widespread species—and *A. plumbeus* from eight localities, all in proximity to the east coast or to its estuaries, but except for the Clyde area the west is practically unexamined. The areas in which ague was common in the eighteenth century are unfortunately those in regard to which little or nothing is known of their mosquitoes; there is therefore no basis for a consideration of the present distribution of Anopheles in relation to the former distribution of ague. In the single recent case of indigenous malaria, the history of which points to infection having been acquired at Kirriemuir (Forfarshire) early in August 1919, the mosquito probably acquired the organism (*Plasmodium vivax*) from an infected soldier there.—A. D. **Hobson**: A study of the fertilisation membrane in the echinoderms. Confirmation is given of the view that the zona pellucida is unnecessary for the formation of the fertilisation membrane. Artificial activation of the eggs of *Asterias rubens* by isotonic solutions of various salts is accompanied by normal membrane formation and shows that a decrease in surface tension is unnecessary for this process. These eggs may be partially activated by sperm during the earliest stages of maturation and show formation of Seifriz's 'protoplasmic papillæ.' Fertilisations of eggs of *Echinus miliaris* were made in media of varying pH and salinity. Under these conditions, elevation of the membrane is caused by the presence of proteins beneath it; the membrane is completely permeable to salts but impermeable to colloids from the time of its first appearance.—W. L. **Calderwood**: Salmon of the River Grand Cascapedea, Canada. Scale examination of a sample of 182 fish from this river shows that the early river life is retarded, the great majority of the fish descending to the sea when three years old. The high average of 23 lb. amongst the adult fish caught is accounted for by the absence of grilse and small spring fish. No grilse has ever been taken in the river. Three consecutive years' feeding in the sea is recorded on the scales of the great majority of the catch.

PARIS.

Academy of Sciences, Feb. 21.—Charles **Moureu**, Charles **Dufraisse**, and René **Chaux**: Autoxidation and anti-oxygen action (xxi.). Experiments at higher temperatures. Application to the problem of the mode of action of the antidetonants. Details of the experimental study of the rate of oxidation by gaseous oxygen at 100° C. of paraffin wax, petroleum, naphthalene, tetrahydronaphthalene, decahydronaphthalene, some animal and vegetable oils. The effect of the addition of various catalysts in slowing down or accelerating the oxidation has also been studied. Starting with the conception that detonation in internal combustion engines (knocking) is due to the formation of peroxides in the liquid phase, a new theory of the action of antidetonants is developed.—Pierre **Weiss**: The atomic moment in complexes of the iron group.—Henri **Villat**: An extension of the method of Oseen.—W. **Slebodzinski**: The quadrics of Riemann space of three dimensions.—Paul **Alexandroff**: The decomposition of space by closed ensembles.—Paul **Mentré**: Certain displacements of a quadric in ruled projective space.—Georges **Bouligand**: Potential and some connected theories.—André **Roussel**: Equally continued functions.—Paul **Flamant**: The development of a linear transformation in a series of powers of the derivative and the extension of a distributive transformation.—Florin **Vasilesco**: The limit values of harmonic functions.—Gr. **Fichtenholz**: The integration of suites of summable functions.—Th. **De Donder**: The relativistic quantification of continued systems.—Henri **Gutton** and Jean **Clément**: The dielectric properties of ionised gases.—G. **Foex** and Mlle. A. **Brunet**: The magnetic properties of manganese pyrophosphate at various temperatures; measurement of the moment of the Mn″ ion. Manganese pyrophosphate follows the law of Weiss exactly over the temperature range, −80° C. to +485° C. The atomic moment of the Mn″ ion is found to be 30 magnetons.—Nicolas **Perrakis**: The constant paramagnetism of pentavalent vanadium; V_2O_5, both in the solid state and in solution, has constant paramagnetism $64·4 \times 10^{-6}$.—Albert **Pérard**: Metrological researches on some neon and helium lines.—C. V. **Raman** and K. S. **Krishnan**: The constant of magnetic double refraction of benzene. On the basis of some simple hypotheses on the structure of the benzene molecule and on the optical anisotropy of the same molecule, the value of the Cotton-Mouton constant can be calculated.—A. **Piccard** and E. **Stahel**: The ether wind. Reply to a criticism of E. Brylinski.—R. **Descamps**: The anomalous rotatory dispersion in the ultra-violet of three aqueous solutions of tartaric acid containing boric acid. With the aid of a photographic spectropolarimeter, measurements of the rotatory power of tartaric acid solutions containing boric acid for wave-lengths varying from λ5780 to λ2537 were made. Contrary to the conclusions of Lowry and Martin, it is found that the $1/[\alpha]$, λ^2 diagrams are not straight lines, and the curves of rotatory dispersion appear to belong to the anomalous complex type in Lowry's classification.—J. **Errera**:

The specific inductive capacity of heterogeneous mixtures.—Charles **Prévost**: Some derivatives of 1 . 3 . 5-hexatriene —**Lespieau**: True doubly acetylenic linear hydrocarbons, $C_{12}H_{18}$, and $C_{20}H_{34}$. Details are given of the preparation and properties of $CH \cdot C—(CH_2)_8—C \cdot CH$ and $CH \cdot C—(CH_2)_{16}—C \cdot CH$.—Maurice **Delaville**: Comparative migratory aptitude of the phenyl and diphenyl groups.—P. **Nottin**: Study of the deposit of starch on the tables of starch factories. It is shown that the conditions realised in the industrial preparation of starch are such that a large proportion of the smaller granules is lost in the waste liquors. An improvement is to be expected if the tables are not inclined.—Mlle. V. **Malychef**: The podzolic soils of the north-west of Tunis.—G. **Ollivier**: The tetrasporangia of *Falkenbergia Doubletii*.—Pierre **Dangeard**: The nucleus and nuclear evolution in the Bangia.—H. **Vignes** and **Coisset**: Calcium and halogen contents of the organism in the course of gestation.—H. **Labbé** and A. **Kotzareff**: The action of radium emanation on glycæmia in white mice —Maurice **Azéma**: The accumulation of fatty reserves by the kidney of *Ascidia mentula*.—J. **Chaine**: The progressive loss of the posterior insertions of certain cephalic muscles.—E. **Derrien**: Porphyrins and parasite worms. The use of Wood's light for the detection of parasites in meat —E. **Kohn-Abrest**. The estimation on the spot of traces of nitrogen peroxide in air.—Léon **Blum** and D. **Brown**: The pathology of uræmia.

GENEVA

Physical and Natural History Society, Feb. 3.—W. H. **Schopfer**: General results on the molecular concentration of the liquids of parasites. The molecular concentration of the parasites depends on that of the medium. There is constant adaptation to a medium the choice of which is caused by other physico-chemical factors still unknown.—L. **Duparc**. The tectonic of Abyssinia. The Abyssinian plateau has undergone an epirogenic movement in steps from the Trias to the Tertiary, with a steady withdrawal of the sea towards the east. A subsidence of recent date has opened a depression (Aouache valley) communicating with the great lakes and with the sea.—Ed. **Claparède**: The greatness of Pestalozzi and its numerical evaluation. If seven contemporary works on pedagogy are arbitrarily chosen the number of pages devoted to Pestalozzi, Rousseau, Herbart, Froebel, Coménius, Locke, Kant, Fénelon, Luther, Rollin, Montaigne, Erasmus, Basedow, Rabelais, the following percentages are found: 24·6, 13·4, 11·8, 9·2, 8·8, 5·8, 4·6, 3·9, 3·8, 3·5, 2·9, 2·9, 2·7, 2 —Sw. **Posternak**: The phosphorus-containing nucleus of milk casein. The nucleus of milk casein containing phosphorus, a proteid elaborated by the maternal organism for the phosphorus nutrition of the young animal, is formed of four serin phosphoric acids.—Em. **Cherbuliez**: The destruction of organic matter with the aid of perchloric acid. The destruction of organic material by oxidation is easily effected, without the intervention of non-volatile substances, with strong sulphuric acid to which has been added some perchloric acid containing a little fuming nitric acid.—G. **Tiercy**: The ionisation of gases and the temperatures of the stars If, applying the formula of M. Saha and of Nernst, in which according to the author it is necessary to correct the constant (Saha's formula), the temperatures of the stars are calculated, the figures found agree remarkably well with those of H N. Russell.

MELBOURNE.

Royal Society of Victoria, Dec. 16.—Gerald F. **Hill**: Termites (Isoptera) from South Sea and Torres Strait Islands. These termites were collected by A. M. Lea in 1924. Of five species representing three genera, obtained in Fiji, two are proposed as new and three are referred to species originally described from Samoa. A number of immature Calotermes from New Caledonia are most probably referable to species previously described from this locality. The above appear to be the first records of termites from Fiji, Rennel, and Murray Islands —F. **Chapman**: A Silurian jellyfish. This new species of a well-preserved jellyfish, *Discophyllum mirabile*, from the Silurian (Melbournian) beds at Brunswick, Melbourne, is closely related to *D. peltatum* J. Hall sp. from the Hudson River series below Troy, N.Y. The Melbo [illegible] fossil has a probable diameter of 6¼ in. It show [illegible] radial and concentric frills of the umbrella, [illegible] gastro-genital pouches and extended tentacles [illegible] forms were fringed Scyphozoa. In associated s [illegible] in which the jellyfish was found there was a [illegible] preserved example of *Bythotrephis gracilis* J. Hall [illegible] which shows the outer cellular layer of the plant.—F. **Chapman**: On a Limestone containing Lepidocyclina and other Foraminifera, from the Cape Range, Exmouth Gulf, Western Australia. The white limestones and chalky beds of this range, discovered by Dr. F. G. Clapp, belong to the older Lepidocyclina series, characterised by *L. dilatata*, a form hitherto unknown in Australian Tertiary deposits. 67 species of foraminifera are recorded, including one new species, *Bolivina spiroplectiformis*, and two species of Ostraceda, *Aglaia clavata* G S.B. and *Cythere lactea* G.S.B., both of which range through the Tertiary in Australia and are found living around the coast. It is concluded that the limestone is of Aquitanian age —Z A. **Merfield**: Total solar eclipse of May 9, 1929. On May 9, 1929, a total solar eclipse will take place and will be visible from northern Sumatra, Malaya, and south Cochin China. This is the only eclipse in the next twelve years to exceed 150 sec. duration. The duration on the west coast of Sumatra will be 5 min. 6 sec., and will afford a splendid opportunity for solar research. A series of meteorological observations has been organised by the Solar Eclipse Circle of the Solar Physics Commission of the International Astronomical Union, and will be made available in due course.—Z. A. **Merfield**: Solar radiation in the Lyman region. From observations made at the total solar eclipse of Jan. 14, 1926, with a moving plate anastigmat grating spectrograph, it is found that Na reaches a height of 3300 km., Ca 1500 km., Ca^+ 10,000 km, Ba^+ 1400 km. Similar results were obtained in Australia in 1922. When the ionisation potentials are taken into account, a comparison of the heights leads to the conclusion that stripped or ionised sodium is not supported by radiation pressure, and as a corollary, that solar radiation is deficient in the Lyman and far ultra-violet regions. The intensity of bright line emission in the far ultra-violet due to highly ionised atoms (taking Ca^{++} as a typical example) depends on a mobile equilibrium and, as a result, radiation from this source is also weak. Solar radiation in this region of the spectrum does not appear to play any important part in the ionisation of the earth's upper atmosphere.—F. Erasmus **Wilson**: New Australian Coleoptera, with notes on some previously described species, Part iii. This paper deals mostly with minute beetles belonging to the family Pselaphidæ, of which thirteen species are described, belonging to the following genera: Schistodactylus (1), Narcodes (2), Schaufussia (1), Pselaphus (6), Tyromorphus (2), and Tmesiphorus (1). A species of Daulotypus belonging to the family Endomychidæ and a species of Techmessa of the family Oedemeridæ are also described as new.

Diary of Societies.

SATURDAY, APRIL 2.

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (Yorkshire District) (at Town Hall, Bradford), at 2.

INSTITUTION OF BRITISH FOUNDRYMEN (Lancashire Branch) (Annual General Meeting) (at College of Technology, Manchester), at 3.—At 4.—B Hird. Absorbed Gases in Iron and the Creation of Gas Holes in the Casting

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Ernest Rutherford The Alpha Rays and their Application to Atomic Structure (3).

MONDAY, APRIL 4.

VICTORIA INSTITUTE (at Central Buildings, Westminster), at 4.30.—Rev. Dr S M. Zwemer. The Place of Woman in Islam

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.—General Meeting.

Royal College of Surgeons of England, at 5.—C. H Shattock: Demonstration of Large Intestine.

Society of Engineers (at Geological Society), at 5.30.—G. C. Workman: Some Aspects of Reinforced Concrete.

Institution of Automobile Engineers (Western Centre) (at Merchant Venturers' Technical College, Bristol), at 6 45.—W. G. Huggins. Automobile Repairs.

Aristotelian Society (at University of London Club), at 8.

Society of Chemical Industry (London Section, jointly with Fuel Section) (at Chemical Society), at 8.—Dr. R. Lessing: The International Conference on Bituminous Coals at Pittsburgh.

TUESDAY, April 5.

Royal Institution of Great Britain, at 5.15 —Prof J W. Cobb: Some Properties of Coke (2).

Zoological Society of London, at 5 30.—B G Boulenger: Exhibition of Photograph of a Crab with Abnormal Claw.—Dr. J. Beattie The Anatomy of the Marmoset, *Hapale jacchus* Linn.—Dr. H. H Woollard: On the Brain of the Marmoset, *Hapale jacchus* Linn.—Major R. W. G. Hingston: Protective Devices in Spiders' Snares.

Institution of Civil Engineers, at 6 —I J. Jones and G. Curry. The Enlargement of the City and South London Railway Tunnels.

London Natural History Society (at Winchester House, E.C.), at 6 30.—R. Green. Bird Portraiture.

Institution of Electrical Engineers (North Midland Centre) (at Hotel Metropole, Leeds), at 7.—Annual General Meeting.

Institution of Electrical Engineers (North-Western Centre) (at Engineers' Club, Manchester) (Annual General Meeting), at 7.—F. H. Clough: The Stability of Large Power Systems.

Royal Photographic Society of Great Britain, at 7.—M Barford: Pictures from the Pyrenees.

Society of Chemical Industry (Birmingham and Midland Section) (at University, Birmingham), at 7.15.—A. A King: Ultraviolet Light.

Institution of Automobile Engineers (at Royal Society of Arts), at 7 45.—A P. Young and L Griffiths The High-Tension Magneto, with Especial Reference to its Design, Manufacture, and Service.

Röntgen Society (at British Institute of Radiology), at 8.15 —J. V Sparks: Uses of Lipiodol as an Aid to Diagnosis in Diseases of the Chest.—F Melville: X-Ray Cinematography.

Royal Anthropological Institute, at 8.30 —Dr. C Singer: Tradition and Observation as illustrated by the Herbal 100 B.C. to 1600 A.D.

WEDNESDAY, April 6.

Geological Society of London, at 5 30.—Prof. H. L. Hawkins and Miss S M. Hampton: The Occurrence, Morphology, and Affinities of the Silurian Echinoidea Echinocystis and Palæodiscus.—V G. Glenday and Dr. J Parkinson: The Kateruk Series and Associated Rocks of the Northern Suk Hills (Kenya Colony).

Institution of Civil Engineers (Informal Meeting), at 6.—F. E. Wentworth-Sheilds. Methods of Preserving Structures.

Institution of Electrical Engineers (Wireless Section), at 6 —P. R. Coursey and H Andrewes: Battery Eliminators or Appliances for the Operation of Radio Receiving Apparatus by Energy Derived from Electric Supply Mains

Institution of Sanitary Engineers (at Caxton Hall, Westminster), at 6.—R. C. N. Newport and H. O. Danger: Kingsbury Main Drainage Scheme, 1924–1926

Electrical Association for Women (at E.L.M.A. Lighting Service Bureau, Strand), at 7.—T. Settle: Women's Place in the American Electrical Industry.

North-East Coast Institution of Engineers and Shipbuilders (Graduate Section) (at Bolbec Hall, Newcastle-upon-Tyne), at 7.15.—W. W. Bath: A Modern Power Station.

Society of Public Analysts and other Analytical Chemists (at Chemical Society), at 8 —C. Ainsworth Mitchell and T. J. Ward. The Sequence of Strokes in Writing.—Dr. D. W. Kent Jones and C. W. Herd: (*a*) Some Observations on the Washing of Gluten from Flour, (*b*) A Numerical Expression for the Colour of Flour.—Dr. H. B. Dunnicliff and Kishen Lal: The Determination of Free Mercury in Commercial Products.

Entomological Society of London, at 8.

Royal Society of Medicine (Odontology and Study of Disease in Children Sections), at 8.—A. T Pitts (Odontology), Dr. R Hutchison (Disease in Children), and others: Discussion on Oral Manifestations of General Disease in Children

Royal Society of Medicine (Tropical Diseases and Parasitology Section) (Laboratory Meeting at London School of Hygiene and Tropical Medicine), at 8.

Institution of Naval Architects (at Royal Society of Arts) —Annual General Meeting.

THURSDAY, April 7.

Linnean Society of London, at 5.—G. C. Robson: Exhibition of Preparations and Lantern-slides illustrating Bacterial Luminescence in Cephalopoda.—Prof. J. Percival: The Species and Races of Wheat and their Relationships.

Royal Society of Medicine, at 5.—W. G Spencer, Dr. H. French, Dr. Fortescue Fox, and others: Discussion on Blood-letting.

Royal Institution of Great Britain, at 5.15.—H J. E. Peake: The Beginnings and Early Spread of Agriculture (2).

Institution of Electrical Engineers, at 6.—E. B Wedmore, W. B. Whitney, and C. E. R. Bruce: A Contribution to the Study of the Number of Tests required to establish the Rupturing Capacity of an Oil Circuit-Breaker.

Optical Society (at Imperial College of Science and Technology), at 7.30 —Prof. C. V. Raman: Huygens' Principle and the Phenomena of Total Reflection —H. W Lee: The Hartmann Formula for the Dispersion of Optical Glass.

Chemical Society, at 8.—H. King: Trypanocidal Action and Chemical Constitution. Part VI. Amphoteric *s*-carbamidoarylarsinic Acids.—E. J. B. Willey: On Active Nitrogen. Part III. Active Nitrogen and the Metals.

Harveian Society of London (at Paddington Town Hall), at 8.30.—T. P. Dunhill, Dr. C. M. Wilson, and others. Discussion on the Treatment of Graves's Disease

Institution of Naval Architects (at Royal Society of Arts).—Annual General Meeting.

Oil and Colour Chemists' Association.

FRIDAY, April 8

Royal Astronomical Society, at 5.—Prof. E W. Brown. Note on Dr Fotheringham's Paper entitled "Trepidation"—P A. Curry The Effect of reversing a small Transit Instrument

Royal Society of Medicine (Laryngology Section), at 5.

Royal College of Surgeons of England, at 5.—Sir Arthur Keith: Demonstration of the Anatomy and Physiology of the Cæcum and Appendix Vermiformis

Malacological Society (at Linnean Society), at 6.

Women's Engineering Society, at 6 30.—Miss E. M. Kennedy: A Business Woman's Trip to America.

Junior Institution of Engineers, at 7.30 —E. Ambrose: Electrical Osmosis.

Institute of Metals (Sheffield Local Section) (at Sheffield University), at 7 30 —E. A Smith: Refined Silver for Electro-plating Anodes.

Royal Society of Medicine (Electro-Therapeutics Section), at 8.30.—Prof. S Russ and Miss G. M. Scott: (*a*) The Growth of Tumours in Tissues Exposed to X-rays and Radium; (*b*) The Action of Radon Seeds upon Tumours and Some Normal Tissues of the Rat.—Dr. J C. Mottram: On the Co-relation between the Experimental and Clinical Radiation of Tumours

Royal Institution of Great Britain, at 9.—Sir Ernest Rutherford: Early Days in Radio-activity.

Institution of Naval Architects (at Royal Society of Arts) —Annual General Meeting.

Oil and Colour Chemists' Association (Manchester Section).—Annual General Meeting.

SATURDAY, April 9.

Royal Institution of Great Britain, at 3.—Sir Ernest Rutherford: The Alpha Rays and their Application to Atomic Structure (4)

PUBLIC LECTURES.

SUNDAY, April 3

Guildhouse (Eccleston Square), at 3.30 —Prof. J. P Bruce: Confucianism.

THURSDAY, April 7.

Fulham Central Public Library, at 8.—J. Weathers: Some Common Mistakes in Gardening.

SUNDAY, April 10.

Guildhouse (Eccleston Square), at 3.30.—Rev. Father Andrew: Christianity.

COMMEMORATION.

Lister Centenary, April 4, 5, and 6.

April 4, at 3.—King's College Hospital.—Sir Watson Cheyne, Bart, Sir Lenthal Cheatle, and others: Lister's Personality.—At 8.30.—Royal Society of Medicine.—Sir StClair Thomson: The Centenary of Lister, Personal Recollections by One of his House-surgeons

April 5 (at British Medical Association, 19 Tavistock Square, W.C), at 11.30 A.M.—Reception of Delegates by the Prime Minister.—At 4.—Conversazione at Royal College of Surgeons of England.

April 6 (Westminster Abbey), at 11 15.—Bishop of Birmingham: Address.—(At Royal Society of Medicine, 1 Wimpole Street, W), at 8 —Discourses by Sir Charles Sherrington, Prof W. Bulloch, and Sir Berkeley Moynihan, Bart., on Lord Lister as Physiologist, Bacteriologist, and Surgeon.—At 9.—Conversazione at Royal Society.

CONFERENCES.

April 7 to 9.

Tuberculosis Society and Society of Superintendents of Tuberculosis Institutions (at Oxford).

April 7, at 2.30 —Prof. L. Cummins: The Bovine Tubercle Bacillus in Immunisation.

April 8, at 10 A.M —Dr. Leonard Hill and others: Discussion on the Defensive Mechanism of the Body against Tuberculosis from the Physical and Chemical Aspect —At 2.15.—Dr. J. Freeman: The Defence of the Body from the Bacteriological and Immunological Side.—Dr. A. G. Gibson. Secondary Infections in Relation to the Progress of Pulmonary Tuberculosis.—Dr A. D. Gardner: The Laboratory Diagnosis of Tubercle.

April 9, at 10 A.M —Dr. J M Martin, Dr. D P Sutherland, and Dr. P. Edwards: The Gaps and Flaws in the Public Health Administration of Tuberculosis.

April 20 to 24.

Journées Médicales Marseillaises et Coloniales (at Marseilles).—Prof. Cantacuzène: The Rôle of the Streptococcus in the Etiology of Scarlet Fever.—Dr. Mayer: Recent Advances in the Treatment of Cancer.—Prof. Ottolenghi: Malaria.—Dr. N. Bernard. Beri-beri.—Prof. Imbert: Bone-grafting

April 25 to 28.

German Society for Internal Medicine (at Wiesbaden) —Discussions on Psychotherapy, introduced by Gaupp and Fleischmann; Results of Recent Functional Investigations of the Stomach and Duodenum, introduced by G Katsch.—A joint meeting with the German Rontgen Society will be held on April 28, with a discussion on the Significance of Rontgen-ray Examination of the Lungs and Mediastinum for Internal Medicine (excluding Tuberculosis), introduced by Dietlen, Assmann, Haenisch and Lorey, and Fleischner.

SATURDAY, APRIL 9, 1927.

Technical Education and Industry.

If any apology were needed for our return to the third volume published by the Committee on Industry and Trade,[1] we would refer our readers to the articles and reports dealing with education and industry which have appeared in our columns during the last two years or so. If those articles and reports be carefully scrutinised, it will be seen that we have attempted, very deliberately, to show not only the necessity, but also the origins, directions, and even deflexions of the rapidly growing tendencies towards a scientific view of education in relation to the structure of modern society. We venture to suggest, too, that our interpretation of the term 'scientific education' has been wide and liberal enough to satisfy the most suspicious guardian of the delectably elusive qualities which are covered by the word 'culture.' Perhaps at another time we shall demonstrate the possibility of realising some of the classical ideals which are still inherent in the life of a community developing under an apparently grey and formless industrialism. In the meantime, the attitude of the present volume towards technical education has a special attraction from the point of view of its significance to the educational movements we have been observing.

Whatever may be our notions of the contributions which are made towards the solution of the problems before the Committee, we believe that its attitude towards the relationship of technical education to industry will do much to strengthen that relationship, and so aid, not only in the industrial reconstruction which lies ahead, but also in the general intellectual progress towards a less anomalous civilisation than exists at present.

It would be easy, perhaps, to criticise the chapter on technical education on certain grounds, the chief of which might be that it is based upon memoranda supplied by government education departments, and that it presents the usual shortcomings of memoranda from such sources, namely, a certain timidity and a platitudinous repetition of possible improvements. But it must not be forgotten that what is platitudinous to the expert may be illuminating and inspiring to the layman; and this volume is primarily for business men rather than for educationists. The charge of timidity, too, loses much of its power when we read the Committee's warning that the volume "is not concerned with recommendations. Its aim is to assemble and analyse facts and tendencies, and by so doing to narrow the range of economic controversy and prepare the way for the intelligent study of the problems by which British industry is confronted."

---

[1] Committee on Industry and Trade. Factors in Industrial and Commercial Efficiency: being Part I. of a Survey of Industries. With an Introduction by the Committee. Pp. v+544. (London: H.M. Stationery Office, 1927.) 5s. net.

Three necessities are, however, made clear: expansion of the scope and number of technical classes; the better adjustment of their relationship with industry; and the constant need to adjust the relations of general and technical education.

Further, if the Committee does not profess to give detailed recommendations, its survey of the present relationship of technical education to particular industries, and its suggestions as to possible improvements, will be greatly helpful to any national industrial organisation, group of employers, or individual employers. Clearly the Committee is doubtful whether full co-operation can be reached by local advisory committees alone. It realises that as yet there has been little serious study on the side of industry of the possibilities of a considered policy of technical school training for young employees; and it is certain that substantial improvements could be suggested if each industry would survey, from its own point of view, the existing facilities, see what gaps need filling and what developments are desirable, take an active interest in the schools and give effective assistance to their conduct. That assistance could take many forms. Lectureships could be founded or subsidised where the public provision is inadequate; grants to part-time teachers to help them to gain wider experience or to improve qualifications; scholarships to promising students; consideration of the methods of filling the more responsible posts; consideration of the number of men needed annually, and the kind of qualifications they should possess; allowance of 'time-off' during working hours to students who have shown diligence and ability to profit by instruction in technical schools.

Three other serious weaknesses of the present system are indicated. The connexions between universities and technical schools are accidental rather than systematic, even though some technical institutions are of university rank and function as technical universities. Premises, too, are unsatisfactory, and work is sometimes conducted "under conditions which are tolerated rather than approved." Finally, the training of teachers presents a difficult problem. Obviously men of experience and skill in trades and processes they teach are essential. But more than such experience and skill is necessary if the highest results are to be attained. Vacation courses have proved extremely valuable; but these, in themselves, are not sufficient. By what other means can this vital problem be settled?

The Committee's view of its problems is shown excellently in some passages which are worthy of reproduction:

> "The vitality of modern industry, like that of an organism, is measured by its power of response to external stimulus and of self-adaptation to modern environment. Mobility (in this sense of the term) does not imply incessant and purposeless movement or change. . . . But it does imply the power of spontaneous reaction to changes in economic conditions and of internal modifications and rearrangement to meet such changes. . . . It applies to modes of preparation for industry and the right adjustment between the functions of school education and workshop training which demand continual modification and re-adaptation both to fit the changing needs of modern large-scale industry and to counteract some of the dangers of excessive sub-division of employments."

Following this line of thought, the Committee does not fail to observe that in our age of flux and transformation, no plan of educational development can be justified which does not maintain unimpaired initiative, flexibility of temperament, powers of adaptation and capacity for co-operation among all the partners in production and distribution. Such a view ought to show very clearly to those who may be fearful, that mere vocational instruction is by no means what the Committee understands by the term 'technical education.'

It would, after all, be too much to expect from a single committee—and particularly from a committee with such wide terms of reference—a solution of the delicate, far-reaching, and many-sided problems presented by an attempt to examine the relationship of technical education to industry. It must not be forgotten that other bodies are also making their contributions to these problems; and if we indicate only some of the activities which we have been observing, it will be sufficient to justify the remark we made above concerning "rapidly growing tendencies."

The Board of Education's Consultative Committee has presented its report on the education of the adolescent; a Committee on Education and Industry (under Mr. D. O. Malcolm) has presented the first part of its report, and is preparing the second part; a Ministry of Labour Inquiry into the general question of apprenticeship is not yet completed; the League of Nations recently held a conference on conciliation in industry, and will shortly continue that conference at Geneva;

finally, the committee brought into being by the many learned and professional institutions and teaching associations under the chairmanship of the late Lord Emmott, is now in the stages of compiling its report on the relationship of technical to other forms of education and to industry. When such activities are reviewed the importance of the present volume may be rightly judged, especially when it is recalled that the President of the Board of Education informed a deputation of the Emmott Committee, last May, that not until he had before him the reports of at least four of these bodies could he begin to formulate the changes which may be immediately necessary.

The contribution of the present volume, too, falls further into its place when we note that it divides its educational problem into three main parts: industrial output is not a mere question of volume, but depends essentially on quality; under modern industrial conditions the relative range and potency of apprenticeship have tended to diminish; school education before entering, and concurrently with, employment has increased in importance.

There is not yet any consensus of opinion, however, as to the mutual relations and limits of workshop training and school education, looked upon as complementary factors. In making its surveys of technical education and apprenticeship, the Committee hoped to be "of assistance in arriving at clearer views on this vitally important question." That the volume achieves that object is beyond all doubt.

Politics as a Science.

The Science and Method of Politics. By Prof. G. E. G. Catlin. Pp. xii + 360. (London: Kegan Paul and Co., Ltd.; New York: Alfred A. Knopf, 1927.) 12*s.* 6*d.* net.

THIS is an able and interesting volume, in which there is at once great learning and considerable power of speculation. Prof. Catlin has an important thesis to maintain, and his urbanity of manner will not conceal from the reader that he is prepared to maintain his ground against all comers. The field, indeed, is already, as if in advance of conflict, strewn with the illustrious dead; at least I seem to discern there the scalps of Plato and Aristotle, Kant and Hegel, exposed as a warning to prospective combatants.

In a sense, Prof. Catlin's book is difficult to review; for it is to be followed by a book already in preparation in which the thesis he here lays down is to be applied to our problems. Obviously, therefore, we shall not fully know what the method he advocates can do until he himself has applied it; and conclusions upon his analysis must be provisional until he has given us the full opportunity to see it at work. But as I understand his views, his purpose is to construct a science of politics which shall seek to do for man in society what the early economists did for the phenomena they survey. It will be abstract and deductive; it will have its axioms and postulates; and the test of its validity will lie in the verifiability of its predictions. Such a science, he argues, must free itself from the shackles which the historian and the philosopher have sought to impose upon it. For values it will have no concern. It will be concerned only with the observed behaviour of men. Assuming that there is a political man with the appetite for power, it will seek to construct the laws of his behaviour in adjusting means to purpose. With right or wrong it will have no more concern than the chemist with the moral qualities of hydrogen. It will be quantitative in character in that, upon the basis of its assumptions, it will seek from observation the largest possible number of examples from which to draw its conclusions. Having made abstraction of ethics, it will be able to approach the facts without a *parti pris*; and, instead of offering futile sacrifices upon the altar of teleology, it will be able to say (p. 199) that the "social situation only admits of certain appropriate measures." For studying what men do, it will be able to tell us what they will do; between the two Prof. Catlin injects a formidable *therefore*; and as this science of politics is refreshed by the constant accumulation of facts about the behaviour of men in their desire for power, as, also, such sister sciences as psychology contribute their due quota of knowledge, we may hope for the discovery of truths which will have value and influence of the same magnitude as those to which the economists have given birth.

There is an air of promising certitude about these propositions, which have at least the merit of interesting audacity; though I observe with a little surprise that Machiavelli is appealed as their benevolent compurgator. For if ever a man had a definite end in view (which, as a passionate Italian patriot, he would have regarded as ethical), if ever, also, a man selected his facts to suit the thesis his experience dictated as best suited to his end, that man was Machiavelli. Perhaps the best thing one can do is to indicate, though with appreciation, some of the doubts to which Prof. Catlin's argument gives rise. The victories of economic science as built in terms of 'economic man' seem to me less outstanding than he claims, and its main successes have been won in spite of, rather than because of, its original and rigorous abstraction. The chief influence of the late Prof. Marshall, for example, was mainly due to the ingenuity with which he transformed the classic economics into something approaching the complexity of the facts; in no other way, moreover, could the economists answer the challenge of Marx, whose own 'economic man' led, by the technique of his construction, to quite different conclusions.

Prof. Catlin, moreover, has a simple faith in facts as such, which, in the social sciences, at least, I do not find it easy to share. They are not born free and equal. The expert interpretation of a social environment is coloured by the personal equation of the observer in a way that is momentously different from an expert interpretation of a physical or chemical environment. What Mr. Justice Holmes has called the 'inarticulate major premiss' of the judiciary is, as a rule, the main clue to their decisions; and yet the best of judges usually believe that they are finding the law in an unbiassed and scientific way. Nor is this all. The maxim 'as men behave, so they will behave,' is, statistically, probably true in a static world; the trouble with this world is that the environment changes at a pace so rapid that the forms of behaviour in one place or period are no clue to those forms in another. I agree that most social situations admit only of certain appropriate measures. But the difficulty here (and I cannot find that Prof. Catlin deals with it) is that the measures have to be chosen in terms of an end deemed right or wrong. We are, in fact, at once outside the realm of scientific politics; for here we are dealing with argument that has reference to ethical value which Prof. Catlin deems irrelevant. I would venture here to add that if the 'political man' were what he describes him to be, in any sense that can be called significant, he represents so small a proportion of mankind that prediction built upon his behaviour would be no clue to the general habits of men. I wish, indeed, that Prof. Catlin had given us some examples of the political 'laws' that his science would establish. Provisionally, at least, he still leaves me with the impression that Burke's 'little mirror of circumstances' would be vital in the battle.

Perhaps I may put my difficulty in terms of an analogy. The Common Law for long proceeded upon the assumption (akin in character to that of Prof. Catlin) that where there was no remedy there could be no wrong; and in order that it might be adequate and effective it was necessary to invent the remedies of Equity, which proceeded upon the assumption (akin to that of political philosophy) that wrongs as such were entitled to redress. My own conviction is that Prof. Catlin's science of politics would need a similar supplement. What seems to me really valid (and brilliantly demonstrated) in his book is its plea for the systematic collection of facts and the deliberate undertaking of experiment. We need, in fact, an inductive study of politics, based on quantitative tabulation, instead of deductions moulded from our private desires. To have shown with wit and point and learning how much might be expected from such a development is the very considerable service Prof. Catlin has rendered us.

Harold J. Laski.

Synthetic Organic Chemistry.

(1) *The Synthesis of Benzene Derivatives.* By Stanley C. Bate. Pp. 229. (London: Ernest Benn, Ltd., 1926.) 21*s*. net.

(2) *The Use of Solvents in Synthetic Organic Chemistry.* By Prof. Donald W. MacArdle. Pp. vii+217. (London: Chapman and Hall, Ltd., 1926.) 15*s*. net.

(3) *Organic Syntheses: an Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals.* Editor-in-Chief: Carl Shipp Marvel. Vol 5. Pp. vii+110. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1925.) 7*s*. 6*d*. net.

THE ever-growing output of research that marks the progress of chemical science is reflected in the increasing size of the chemical journals; and the task of the researcher whose text-books these form becomes more onerous each year. The work is lightened by the publication of the Chemical Society's Annual Reports, and by the appearance from time to time of monographs dealing with the more important theoretical aspects of the problems under investigation, but the wealth of information 'tied up' in the experimental work of the original papers is not so easily rendered accessible. This difficulty has been partially solved by the compilation of such comprehensive treatises as Houben-Weyl's "Die Methoden der organischen Chemie," or Meyer's "Analyse und Konstitutionsermittlung organischer Verbindungen," and the first two of the three books under review are frank attempts on the part of the authors to provide for English-speaking chemists similar correlated information on definite problems connected with laboratory practice.

(1) Mr. Bate seeks to give in a short and concise form the various methods available for the synthesis of organic compounds that may be of utility both to senior students and research chemists; and the present pioneer volume is concerned with the synthesis of derivatives of benzene. The subject is discussed in twelve chapters, each dealing, usually, with one type of reaction. Thus in the chapter on nitro compounds, the nitration of different types of compounds by means of nitric acid is described; then follows a description of other methods of nitration; of the conversion of amines into nitro compounds; of anomalous cases occurring in nitration; and finally, the effect on certain groups of the presence of the nitro group in the molecule is discussed. The text contains full references to the original papers and patents up to April 1925, as in very few cases is sufficient detail supplied to make the reader independent of the original memoir. The reviewer suggests that in a future edition the names of the investigators be given as well as the references, in order to facilitate cross reference to abstract journals; and also, that the present scanty index be considerably extended.

The general arrangement of the book is excellent, the printing clear, and the text remarkably free from errors, but in a few cases confusion arises from the use of italics at the beginning of a paragraph for the introduction of a new main section, whilst a sub-section is placed under headlines in heavy type. Not a few formulæ are faulty owing to the misuse of the dot and bracket; and the printing of such expressions as "to react the substance," and "the substance to be amidated," and "oxy" for "hydroxy," are not pleasing to the English ear. These minor blemishes do not detract from the value of a book of such excellence that it should form a unique and most useful addition to the reference library of the organic chemistry departments of all university and technical institutions.

(2) Prof. MacArdle's book is the first part of a treatise on the operative technique of synthetic organic chemistry, similar in a general way to the first sections of the well-known German works of Lassar-Cohn and of Weyl. The first chapter is devoted to "General Considerations," and treats of solution, methods of bringing about solution, choice of solvent, interliquefaction, crystallisation, solvent of crystallisation, and mixed crystals. In the following seven chapters the uses of the various types of solvents are discussed, the question of the purifying of the substance being treated critically and the fullest practical details being supplied. These chapters are rich in references to special cases in which the solvent in question has proved of unique value, and also of instances when anomalous reactions have occurred which limit the use of the solvent. The remaining two chapters are devoted to a consideration of "Special Means to Induce Crystallisation" and to "Salting Out"; a full bibliography and two exhaustive indexes are appended.

The arrangement of the book and the presentation of the subject leave nothing to be desired; for, in addition to its eminently practical value, the book is a readable one and holds the interest of the reader from the first page to the last.

The statement on page 138 that the dangers attending the use of dimethyl sulphate have been very much exaggerated cannot be generally endorsed, for in the experience of the reviewer more than one case of serious and prolonged indisposition has resulted from the use of this substance without special precautions being taken to remove all vapours in an effective draught.

(3) The last of the three books with which this review is concerned differs widely in scope and purpose from the others. It is the fifth volume of "An Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals"; and indeed so eminently satisfactory are the methods described therein that the issue of the yearly volume marks a red-letter day in the organic laboratory. Since the publication of the first volume, when the editors invited the co-operation of other organic chemists, the response has become wider each year, and in this volume twenty-four of the thirty-three preparations have been submitted by eighteen contributors.

M. A. W.

The American Mongolian Expedition.

On the Trail of Ancient Man: a Narrative of the Field Work of the Central Asiatic Expeditions. By Dr. Roy Chapman Andrews. With an Introduction and a Chapter by Henry Fairfield Osborn. Pp. xxiv + 375 + 61 plates. (New York and London: G. P. Putnam's Sons, 1926.) 25s. net.

NORTH-EASTERN Asia has entered the field as one of the competitors with south-western Asia as the home of man. The discovery of some fossil vertebrates that are common to Europe and western America but are absent from eastern America led Prof. H. F. Osborn in 1900 to predict that these animals had developed in northern Asia and thence migrated eastward into Europe and westward into America. The ocean they crossed was therefore the Pacific and not the Atlantic. Faith in this theory led Dr. R. C. Andrews to organise an expedition to search for the remains of these animals in the steppes which they must have crossed during their migration from inner Asia to the Rocky Mountains. The generosity of American patrons of science provided £50,000 for the purpose, and Dr. Andrews led to Mongolia a series of well-equipped expeditions which there made several sensational discoveries. The most dramatic was the finding of the eggs of Cretaceous dinosaurs. They were found in such abundance in one locality that one Mongolian woman brought in fragments of egg-shells in tinfuls. The eggs belong to three genera, one of which, Protoceratops, is a primitive form of the Ceratopsidæ. Dr. Andrews describes this locality as a dinosaur incubator, and he attributes its selection as the breeding-ground to the nature of the sand, which would have formed comfortable nests.

Of still greater importance was the discovery, also in the Middle Cretaceous beds, of some mammal skulls. The first found had been sent to New York as a reptile, and recognised by Dr. W. D. Matthew as a primitive mammal. Stimulated by his report of the importance of the discovery, the search was renewed and other specimens found. A preliminary account of the skulls is given in the volume, but a more detailed account has been recently published elsewhere. The expedition also discovered a series of important Eocene mammals. The first of the vertebrate fossils found by the expedition were some bones of the Baluchitherium, an Oligocene mammal, which was discovered by Cooper in northern India. The expedition found later a skull and a skeleton of this mammal, and Dr. R. C. Andrews was led by the discovery to the expectation that, as the human family probably began to diverge from the ordinary primates in the Oligocene, the remains of some primitive ancestors of man should be found in Mongolia.

Large numbers of stone implements were found; they represent two periods—Neolithic and Upper Palæolithic. The age of the latter is suggested as Azilian. Some members of the expedition were at first under the impression that the rough stone cores represented a pre-Chellean culture; but ultimately they were convinced by the large series collected and arranged by the archæologist, Mr. Nelson, that the cores were the residue of Upper Palæolithic flaking. Nothing human was obtained by the expedition earlier than the Mousterian, of which implements have already been found in China, in the valley of the Hoang-ho. While the palæontologists were excavating the fossils, the two geologists with the expedition—Prof. Berkey and Mr. F. K. Morris—surveyed the area, worked out its history, and thus made a valuable contribution to Asiatic geology. Amongst other points of interest they find that there is no evidence of glaciation in the district, except in some small corries on the highest hills.

The volume tells the narrative of the expedition. It is graphically and racily written, and gives a delightful picture of a group of men in cordial co-operation and all enthusiastic in their work. Probably in the effort to be popular the author constantly states the age of the beds in years, reporting, for example, that the earlier implements date from 40 thousand, and the later from 15 thousand years ago; such estimates are about as useful as if a historian tried to date an Act of Parliament by reference to the birth of John Smith. The book is well illustrated by photographs showing the expedition at work and the nature of the country, and by ideal pictures of the fossils skipping about in their native haunts. J. W. Gregory.

Our Bookshelf.

The Year-Book of the Scientific and Learned Societies of Great Britain and Ireland: a Record of the Work done in Science, Literature, and Art during the Session 1925–1926, by numerous Societies and Government Institutions. Compiled from Official Sources. Forty-third Annual Issue. Pp. vii + 399. (London: Charles Griffin and Co., Ltd., 1926.) 18s. net.

To those who have used this work of reference, the new issue requires no commendation. For those who have not yet handled it, emphasis may be laid on the words from the title-page: "Compiled from Official Sources." The information provided as to the titles, addresses, officers, and activities of the scientific and learned societies and Government institutions in Great Britain and Ireland has been obtained from officials of the societies concerned, so the volume serves as a directory. In addition, the lists of authors and titles of papers presented before each society during 1925 gives some indication of the amount and direction of progress made in science and the arts. Take, for example, the Royal Society: the total number of papers, 226, shows great activity in the scientific world, while the fact that nearly three-quarters of them were published in Series A of the *Transactions* or *Proceedings* testifies to the fertile field of the mathematical and physical sciences.

The various societies are grouped according to the subjects of their interests, beginning with those dealing with science generally. As regards classification, there will obviously be differences of opinion; we think, however, that the Rontgen Society would be better in the Physics Section than under Chemistry and Photography, while the Spelæological Society (University of Bristol) is certainly archæological rather than biological. The index, however, soon smooths out little difficulties of this kind. The new address of the British Cast Iron Research Association, at 24 St. Paul's Square, Birmingham, was probably announced too late for insertion. We are still of the opinion that all the research associations in Great Britain now in existence should be included and indexed under 'Research.' Some of the more recently formed scientific bodies have not yet appeared in the volume, but meanwhile we must be grateful for the valuable collection of data with which the publishers of this annual continue to supply us.

Elemente der exakten Erblichkeitslehre: mit Grundzügen der biologischen Variationsstatistik. Von Prof. Dr. W. Johannsen. Dritte deutsche, neubearbeitete Auflage in dreissig Vorlesungen. Pp. xi + 736. (Jena: Gustav Fischer, 1926.) 32 gold marks.

THIS well-known book, which was first published in 1909, has now reached its third edition. It is still divided into thirty 'lectures,' but various additions and alterations have been made. More attention is paid to Sheppard's correction for class variants and to Bravais' formula for reckoning the coefficient of correlation. In the latter formula the value of every variant, and not merely that of the classes, enters into the result, and the method can also be used for alternative as well as quantitative variations. The chapters on selection have been extended and those on Mendelism re-written in the light of the more recent work. The word 'gen' is used throughout for the hereditary unit, and Bateson's term 'allelomorph' has been shortened to 'allele,' with a result which would not be very happy if the word were used in English form. In its present form the work will continue to be of great use to geneticists, since it gives in convenient form the various statistical methods used in genetical investigations. But more than this, it is a discussion from the author's characteristic point of view of large fields in experimental genetics.

R. R. G.

Prehistoric Man and the Cambridge Gravels. By the Rev. Frederick Smith. Pp. viii + 121 + 30 plates. (Cambridge: W. Heffer and Sons, Ltd.; London: Simpkin, Marshall and Co., Ltd., 1926.) 7*s.* 6*d.* net.

THE Rev. Frederick Smith, the author of a book on the Stone Ages in North Britain and Ireland, has been engaged in archæological research for more than sixty years. He began to collect from the Cambridge gravels when he was a boy, and he returned to his old hunting-ground in 1924. He has collected many thousands of specimens, and the constant recurrence of certain forms has convinced him that his specimens are implements of various kinds—arrowheads, spear heads, hatchets, knives, and flakers, piercers, and saws—and that certain of them were fitted with shafts. In addition he has found sculptures—a baboon, eagle's beak, an oyster shell, and so forth. The date attributed to them is pre-Chellean, Chellean, and Acheulean. Mr. Smith argues that though the early archæologists were ridiculed and rejected, their views were afterwards accepted, and by analogy claims indulgence for his own views. The argument is as dangerous as its converse. Mr. Smith figures a number of the specimens which he maintains are implements, showing them with and without hafts, but his illustrations still fail to convince.

Handbuch der biologischen Arbeitsmethoden. Herausgegeben von Prof. Dr. Emil Abderhalden. Lieferung 199. Abt. 9: ***Methoden zur Erforschung der Leistungen des tierischen Organismus***, Teil 4, Heft 2. ***Methoden der Erforschung bestimmter Funktionen bei einzelnen Tierarten. Methoden zur Erforschung des Vogelzuges***, von J. Thienemann; ***Methoden zur Behandlung der Atemphysiologie der Insekten***, von Albert Koch; ***Die Verfahren zur Erforschung der Tierfluges***, von Oskar Prochnow. Pp. 123-294. (Berlin und Wien: Urban und Schwarzenberg, 1926.) 7·50 gold marks.

THE first article on the speed and height of the flight of birds is a very brief account of the subject. In the second one, on the respiration of insects (about 80 pages), the function of the spiracles and the movements which ventilate the tracheæ are discussed, and the principal methods for investigating the movements are described and illustrated. Due attention is given to the physical and chemical aspects of the problem, *e.g.* the technique of gas microanalysis. The third article discusses the flight of insects and of birds and the methods which have been employed in the elucidation of the movements and of their mechanics.

Surface Equilibria of Biological and Organic Colloids. By Dr. P. Lecomte du Noüy. (American Chemical Society Monograph Series.) Pp. 212. (New York: The Chemical Catalog Co., Inc., 1926.) 4.50 dollars.

IN the measurement of surface tension the 'ring' method has the great advantage of rapidity, so that variations are readily discovered; and in the hands of the author of this volume it has proved a most useful weapon of research. The book deals largely with the work of the author, but although its scope is therefore not so wide as the title might imply, it is full of interest to the biologist and the physicist. An ingenious method of deducing the three dimensions of the sodium oleate molecule (leading to a value for Avogadro's constant in remarkable agreement with that obtained in very different ways), the size of the albumin molecule and the differentiation of normal and immune serum are among the subjects dealt with in this work, which should prove singularly attractive even to those who are not specialists.

The Origin of the Earth's Surface Structure.

In the *Journal and Proceedings of the Asiatic Society of Bengal* (vol. 8, No. 9; 1912) there is a paper by Dr. L. L. Fermor entitled "Preliminary Note on the Origin of Meteorites."

In approaching his subject Dr. Fermor deals with the effects of pressure in determining the mineral constitution of rocks. He refers especially to the case of eclogite, wherein the development of garnet, and occasionally of diamond, is remarkable. The first represents the allocation of the normal elements present in a gabbroid magma in such a manner as to give rise to the development of minerals possessing the maximum density; the second, the same effect in the relatively rare case of carbon being present. He instances the well-known occurrence of both diamond and garnet in certain eclogites of South Africa. Dr. Fermor concludes that there must be what he calls an infra-plutonic zone deep in the earth's surface materials, and probably extending far downwards, composed of rocks of eclogitic type and, probably, at such a temperature as maintains them in a plastic-solid state. He explains the occasional appearance of this infra-plutonic rock at the surface as due to special conditions whereby cooling forestalls the effects of reduction of pressure during the ascension of the rock; which in this way attains a region of negligible pressure while preserving a mineral structure proper to very great depths. The well-known kelyphite rims, sometimes surrounding the garnets of eclogites, indicate a partial break-down into mineral structures of lesser density.

The recent results arrived at by Dr. Harold Jeffreys (NATURE, Sept. 25, 1926), based upon the velocity of transmission of compressional seismic waves, point to the existence of a zone of the density of basaltic glass underlying the granitic continents; the basaltic zone being succeeded downwards by one which Dr. Jeffreys suggests may be dunite. The granitic layer may possess an average thickness of from 20 km. to 30 km. The basaltic zone may have a thickness of about 20 km. The underlying layer may extend to a depth of 1500 km.

Daly has contended for the existence of a general basaltic layer extending beneath the continents and oceans. Other eminent petrologists have held this view. We desire here, in the first place, to cite some recently added evidence in its favour. Washington's discovery of the chemical resemblance of the plateau basalts ejected at various times and at different points of the earth's surface, might in itself be regarded as conclusive. The resemblance, however, seemed to fail respecting the radioactivity of the rocks; the Oregonian basalt showing a much higher radioactivity than the Deccan and Hebridean (*Phil. Mag.*, Nov. 1924). However, we pointed out at the time that the authenticity of our 'Oregonian' material was not perfectly assured. Thanks to the courtesy of Prof. Daly, Prof. Landes, and Prof. W. P. Smith, we have been able to examine specimens of Oregonian basalt of undoubted authenticity, and even a fragment from the specimen chemically investigated by Washington. The average radium and thorium contents of Oregonian rocks from twelve localities come out as closely alike with those already determined for the Deccan and Hebridean areas. Those who are inclined to limit radioactivity to local conditions will find it difficult to explain away the chemical and radioactive similarity of these enormous and widely sundered outpourings.

Coming now to the third terrestrial layer—the high-density medium underlying the basaltic—it appears that there is no necessity, so far as seismic evidence is concerned, to suppose this layer to differ from the basaltic save in the matter of its mineral structure. The gabbros and the eclogites are magmatically the same. We have found that an eclogite possessing the density 3·415 yielded upon fusion a glass which when cold possessed a density of 2·746, which agrees with the results obtained by Day, Sosman, and Hostetter (*Am. Jour. Sci.*, 37, 1914) for the density of basaltic glass. The density of eclogite—the piezocrystalline form of the magma—would agree with the seismic evidence. It ranges from 3·2 to 3·5. That of dunite is 3·3. We see, then, that seismic evidence is not opposed to the simplifying assumption that the sub-continental materials as revealed in the plateau basalts may extend downwards to a depth approximating to 1500 km. In short, the assumption of the eclogitic character of the third terrestrial layer involves little more than the acceptance of Dr. Fermor's inference that the pressure conditions which convert carbon into diamond in eclogites is also responsible for the high-density mineral structure of these rocks.

However, there is something more to be said. We have found recently that the eclogites possess on the average barely one-half the radium and thorium contents of the plateau basalts. An explanation, we believe, can be offered for this apparently contradictory result; an explanation which, if it is correct, seems to throw light on the origin of terrestrial surface structure and surface history.

Yet the explanation we would suggest is very elementary and simple. We assume that the outer material of the primeval earth was originally compounded of all those siliceous aggregates afterwards differentiated into the layers we have been discussing; and that it was not throughout uniform in chemical composition. There was heterogeneity on, probably, a very varied scale; in some places coarse, in others fine: and this heterogeneity of distribution and association affected the stable chemical elements as well as those that are radioactive. These assumptions seem to be the most general we can make as well as the most probable.

Let us consider first the effects of heterogeneity in the distribution of radioactive elements. This would carry with it thermal heterogeneity. Some parts would melt before others, and when their surroundings were melted would retain a higher temperature and lower density. These parts would gravitate upwards. Again, some parts of lesser radioactivity would retain for longer periods the solid state. In the depths this condition would be especially effective, for here the pressure confers upon the medium the maximum density, as we have seen. Thus the temperature and pressure conditions conspire to preserve to, or confer upon, the medium a high density; and accordingly it gravitates downwards when the fusion of its surroundings permits. Hence it would come about that such gabbroid magma as was poor in radioactive elements—poor in uranium, in thorium, and in potassium—would retain the solid state longest and sink into the depths. It is a fact that eclogite is poorer than the plateau basalts in all three radioactive elements. Respecting potassium, the mean content of K_2O in the five plateau basalts analysed by Washington is 0·89 per cent. The mean

K_2O content of seventeen eclogites cited by Rosenbusch is 0·70 per cent., and of eleven cited by Mlle. Brière (*Bull. Soc. Française de Min.*, 43, 1920) it is 0·37 per cent. They are, in fact, at once the poorest in the heat-producing elements and the densest rocks known.

There would, also, exist a lack of homogeneity respecting the distribution of the non-radioactive elements. Some parts would be richer in silica, alumina, etc.; others in metallic oxides, etc.; such parts would for ever seek to ascend or to descend. Or, in times of thermal loss, certain well-known factors concerned in magmatic differentiation would operate in the same directions.

The final results should be precisely what we find; a highly siliceous and aluminous surface layer rich in radioactive elements and—what seismic evidence reveals—in the depths, rocks of maximum density and, as we now find, of minimum radioactivity. Should these inevitable final conditions be disturbed by the circulation attending a great revolution, they would gradually be re-established during the long later period of thermal loss. We perceive, in short, that heterogeneity in the circumstances is not stable, but must result in radioactive and gravitational stratification. Reversing our line of argument, we might justify our assumption of initial heterogeneity in recognition of the revealed surface structure of the earth.

If these views are correct, it would appear that radioactivity mainly has been responsible for the stratification of the earth's outer materials. It has determined the origin of the radioactively rich and gravitationally light continental layer, of the isostatic layer of intermediate radioactivity and density, and of that more deep-seated layer which only at long intervals takes part in the great events of surface history: the major revolutions ("The Halley Lecture," 1924, pp. 31 *et seq.*, and A. Holmes, *Geol. Mag.*, July 1926). In short, it would appear to have fashioned those structural conditions which have been responsible for geological history and for the development of life upon the globe.

Further evidence of stratification in the earth's great basaltic layer is revealed in the petrology of the oceanic islands. The island basalt—which we must regard as representing the same lava as composes the ocean floor or prevails immediately beneath it—is richer in all the radioactive elements, and at the same time lower in density, than are the plateau basalts. These island lavas reveal, in fact, the final differentiation of the substratum where it attains the surface of the globe; a differentiation referable to physical causes similar to those we have referred to above.

As bearing on all our views of earth-history we would point out that the low radioactivity of eclogite directly affects estimates of geological time based upon the period required to bring about a major revolution. The length of previous estimates will require to be doubled.

Experiments on highly penetrating Radiation from the Earth.

MEASUREMENTS of penetrating radiation of the earth executed at Piatigorsk (in the Caucasus) by means of a portable electrometer covered with lead 1 cm. thick have shown that, though the same apparatus was used, the intensity fluctuated according to the stations of observation where the measurements were made. The fluctuations of intensity were especially marked in places rich in radium, where differences of so much as 100 per cent. were observed between stations separated by a few metres only.

Measurements made at the same observing stations during a period of three years have shown the intensity to be constant and independent of meteorological conditions, and of fluctuations of emanations contained in the atmosphere, within the limits of sensibility of the apparatus.

Measurements of the prevalence of radioactive elements in the upper layers of the soil have shown its constancy, which indicates that the fluctuations were caused by deeper strata only.

The application of four hoods fitting one into the other, each 2 cm. thick and covering the apparatus from above and laterally, and likewise of four flat lead screens covering it from beneath, has shown the influence of the hoods to be very slight, while that of the screens was quite important, indicating that the electrometer was acted upon chiefly from below.

The thickness of lead protecting the apparatus from above, laterally, and from below, having been varied from 0 to 8 cm., the computation of coefficients of absorption was rendered possible. It appeared that the coefficients of absorption by screens varied from 0·45 to 0·06 for 1 cm. Values approaching the lower limit were frequently encountered at different stations. In most cases the value of the coefficient of absorption diminished with an increase of thickness of the lead screens; that is to say, a complex of radiations was being dealt with, some of them possessing a much greater radiating capacity than the γ-rays of radium C. The radiations are directed from below, and their source lies apparently in radio-elements diffused in upper strata of the soil.

The full report of this work will be published in the *Bulletin of the Institute of Practical Geophysics*, Leningrad.

Spectrographic Observations of the Second Green Line of the Auroral Spectrum.

I THINK that all those who have worked on the spectrum of the aurora will congratulate Prof. Vegard on the notable success he has achieved in photographing so distinctly the line or band about λ5238 as recorded in his letter in NATURE of Mar. 5, p. 349. The technical difficulties which he had to overcome were formidable.

The present letter is not written in an unsympathetic spirit, but it seems worth while to point out that an interpretation alternative to that of Prof. Vegard is possible. He identifies the band with one which he has observed in the phosphorescent spectrum of frozen nitrogen. But there is a band in about the same position in the negative band spectrum of gaseous nitrogen. Ångström and Thalén (quoted by Kayser in "Spectroscopie") gave the wave-length as λ5227·5. The stronger bands of the same series come out with great intensity on Prof. Vegard's photograph as on other photographs of the auroral spectrum: so that it is probable, indeed nearly certain, that a long enough exposure would bring out this band.

If, as would appear from Prof. Vegard's letter, precise wave-length comparisons are not feasible, the criterion of intensity distribution remains. I hope Prof. Vegard may think it worth while to photograph this negative nitrogen band with the same instrument, for direct comparison with the auroral spectrum. It is not unlikely that this would help a decision.

Is Darwinism Dead?

In Nature of Feb. 19, Sir Arthur Keith brought against me two specific accusations: (1) That I denied in my book "A Companion" (p. 12) the possibility of birds descending from reptiles; (2) that I had given a false reference to Vialleton's high authority. There was a clear issue: (1) Had I said this? (2) Had I misrepresented my authority?

On Mar. 8 I wrote you a brief letter showing that Sir Arthur Keith was ignorant of the great work of Vialleton to which I had alluded, and giving four detailed references. This letter you did not print. In its place you issued, on Mar. 19, a 'comment,' in which you substituted other issues, and repeated as your own the first of Sir Arthur's blunders.

I am therefore compelled to send you this further letter in order that readers of Nature may be acquainted both with the real issue and its upshot.

(1) I made no affirmation upon the descent of birds. What I did say was that a very great authority (Vialleton) had given strong arguments against the reptilian origin of birds with the natural effect of such an authority so reasoning.

(2) So far from giving a false reference, I had worked upon Vialleton's latest and famous work, and in my letter I gave four page references (585, 588, 590, 592) to that work: of which apparently Sir Arthur had no knowledge, or he could not have blundered as he did.

Your comment leaves your readers under a directly wrong impression upon both points. You re-affirm the error of the first; you make no mention of my specific references in the letter, but only say vaguely that I have caught my critic "referring to the wrong book."

My accuracy, and Sir Arthur Keith's lack of that quality on this issue, can be verified as plain matters of fact by any one who will consult the texts in question.

H. Belloc.

Reform Club,
Pall Mall, S.W.1, Mar. 28.

Mr. Belloc is under a triple misapprehension. He believes he gave 'references' in his "Companion"; he did not. He left his readers to guess which Vialleton he had in mind; I guessed the right one, and quoted a pertinent passage from Prof. L. Vialleton's best-known work. If Mr. Belloc had been well advised he would have accepted that quotation without comment, for it is less discordant with modern knowledge than the passages of the later compilation to which Mr. Belloc has directed my attention.

In the second place, Mr. Belloc is under a misapprehension as regards Prof. L. Vialleton's range of original work; that writer has never claimed to be an 'authority' on the evolutionary history of birds, nor is he so regarded by zoologists or palæontologists of any country. I am sure Prof. Vialleton will smile when he learns of the claims which Mr. Belloc now makes for him.

Mr. Belloc's third misapprehension relates to the present state of our knowledge regarding the evolution of birds. The evidence drawn from embryology, geology, and anatomy leaves the expert student in no doubt as to their origin; they arose from a reptilian ancestry.

The Atomic Weight of Silver.

The following few lines give a necessary elucidation to my critical note and to the answer given by Messrs. H. B. Baker and H. L. Riley (Nature, Mar. 5, p. 348). My principal first theoretical argument is based on the *interdependence* of the atomic weights of the elements silver, nitrogen, and chlorine, resulting from the classical life-work of Richards and his school, in which I have the greatest confidence. If the atomic weight of silver = 107·876, then nitrogen = 14·006 ± 0·0011, and chlorine = 35·456 ± 0·002, most probably 35·458. If we accept Baker and Riley's value, silver = 107·864, then nitrogen would become 13·999, a value exceedingly improbable, especially having regard to the fact that Baxter found recently (*Proc. Amer. Acad.*, **12**, 12, p. 699, Dec. 1926) by an extremely careful physico-chemical research the value N = 14·006(7), which confirms the higher atomic weight of silver, namely, 107·876. This important argument was not referred to by Messrs. Baker and Riley.

My second, no less important, practical argument was based on the assumption that Messrs. Baker and Riley have lost exceedingly small quantities of silver vapour on fusing the metal in hydrogen, so that the atomic weight found by them is slightly lower than the true one. They did their best to convince themselves that no *visible* condensation of metallic silver could be observed in their tubes, and they say that they have begun a new series of experiments to investigate the volatility and condensability of silver. I beg to remark that some experiments on a large scale in this direction were published by J. S. Stas so long ago as 1865 ("Œuvres complètes," T. I, p. 457), who was my first "atomic weight teacher" in 1875 (but who would read such 'antiquated' papers to-day?). He describes the distillation of 50 gm. of his purest silver in the flame of the oxy-hydrogen blowpipe and says: "Je dois avouer toute fois que, dans les opérations que je viens de décrire, la moitié *au moins* de l'argent employé a été perdue. En effet, il a été entraîné à l'état de vapeur bleue pâle avec le courant de *gas tonnant*, quoiqu'il fût cependant modéré, et sans excès trop grand d'oxygène; il a été répandu dans l'air ambiant dont il a troublé la transparence, et auquel il a communiqué une saveur métallique très sensible."

From this important observation it follows that when silver once passes into the state of vapour it is not easily condensed in a solid state, but forms only a colloidal dispersion as a fog. Large quantities of silver heated in tubes give a condensation of the metal, but when a small quantity was heated and fused, the silver vapour—the weight of which was, in the said experiments, of the order of 0·0001 gm. and which would occupy in the solid state 0·00001 cm.^{3}—may have passed out of the apparatus.

Messrs. Baker and Riley say that they controlled the weight of the fused silver obtained by repeatedly melting and weighing it to constant weight. But the question arises: What was the weight of the silver obtained in a fine state of division immediately after decomposition of its oxide by heat and before fusion? Such silver has a very great surface, and during fusion a small loss by evaporation may have taken place. After fusion, its surface has become very small and, last but not least, it was "coated with a very thin film of dross consisting of silica." To these circumstances the fact is very probably due that no appreciable loss of weight of the silver was observed after repeated fusion.

Bohemian University, Prague, Mar. 10.

Convection of Heat in Fluid Flow through Tubes.

THE convection of heat to or from the walls of a circular tube conveying fluid in turbulent motion has been studied by a long line of investigators, among whom may be mentioned Joule, Reynolds, Stanton, Nüsselt, Soennecken, Jordan, Stender, Heinrich, and Stückle. From dimensional considerations Rayleigh (NATURE, Mar. 18, 1915, p. 66) deduced a formula which, written in non-dimensional form, is equivalent to

$$\frac{ad}{k}=\phi\left(\frac{Vd}{\nu},\ \frac{k}{s\mu}\right), \quad . \quad . \quad . \quad (1)$$

where a = coefficient of transmission of heat.
d = diameter of tube.
V = mean velocity of flow.
k = conductivity of fluid.
μ = viscosity of fluid.
ν = kinematic viscosity of fluid $=\mu/\rho$.
h = diffusivity of fluid $=k/s\rho$.
s = specific heat of fluid.
ρ = density of fluid.

For gases Stanton (Tech. Report Adv. Committee for Aeronautics, 1912–13) gave a formula reducible to

$$\frac{ad}{k}=\text{const.}\left(\frac{Vd}{\nu}\right)^{n}, \quad . \quad . \quad . \quad (2)$$

in which $n=0\cdot75$ approximately for smooth tubes.

Nüsselt (*Z. V. d. I.*, 1909) proposed a formula for gases reducible to his later form:

$$\frac{ad}{k}=\text{const.}\left(\frac{Vd}{h}\right)^{n}, \quad . \quad . \quad . \quad (3)$$

which is equivalent to (2) ($n=0\cdot78$).

Formulæ for water of the form:

$$a \text{ proportional to } V^{n}, \quad . \quad . \quad . \quad (4)$$

have been proposed by Stanton (*Phil. Trans. Roy. Soc.*, 1897), Soennecken (*Forsch.* Heft 108/109), Stender ("Wármeubergang an stromendes Wasser," Springer, 1924), and others. These formulæ do not make explicit mention of the conductivity. Stender finds that the index 'n' depends on an equivalent mean temperature $\tau°$ C. $=0\cdot9Tm+0\cdot1Tw$, where Tm = mean water temperature and Tw wall temperature. Experiments with oil have been carried out by Heinrich and Stückle, but not fully analysed (*Forsch. Arb.* Heft 271).

The object of the present note is to suggest a general formula applicable to all fluids, liquid or gaseous, under conditions of turbulent flow in circular tubes, namely:

$$\frac{ad}{k}=0\cdot0260\left(\frac{Vd}{\nu}\right)^{f\left(\frac{k}{\mu s}\right)}, \quad . \quad . \quad . \quad (5)$$

in which $f(k/\mu s)$ is given approximately by the following values:

$h/\nu=k/\mu s$	0·01	0·10	0·40	1·30
$f(h/\nu)=f(k/\mu s)$	0·97	0·895	0·835	0·785

which lie well on a smooth graph.

This formula agrees well with the experiments of Heinrich and Stückle for oil, those of Stanton, Soennecken and Stender for water ($\tau=10°$ C. to $\tau=70°$ C.). It also agrees as well with the results of Jordan, Nüsselt, Pannel, and others for air, as these agree amongst themselves.

A crucial test of the value of formula (5) would be given by experiments with mercury for which the value of $k/\mu s$ lies outside the range of the experiments referred to above.

A complete formula should take account of the ratio of length to diameter of tube, or else the ratio of initial to final excess temperatures, but (5) is put forward as a step towards the correlation of the results of diverse experiments in which the ratio of length to diameter of tube exceeds about 20.

The Polishing of Surfaces.

MAY I describe one or two surface-polishing experiments?

1. The first is more easily described than performed. Prepare a polished biprism having a supplementary angle of 4 or 5 seconds. Continue the polishing of one surface. The debris removed will be carried over the edge and deposited in the minute wedged space between the other surface and the tool. When this space is filled, a continuous perfectly polished surface will be produced and only an appearance of interference on the lee side will betray the original biprism character of the specimen. But under the microscope, and by the judicious use of a steel needle, it will be found that the debris is really only compacted; it can gradually be broken away and removed. The underlying surface upon which the debris has been deposited retains its original optical polish.

This seems to indicate that, once a group of molecules has been torn from the embrace of its associates, it is practically impossible under polishing conditions to force it back within the region of molecular cohesion.

2. A thermometer embedded in the polishing tool as nearly as possible in contact with the surface will record a rise of temperature of disappointingly small amount. If polishing is due to actual fusion of the 'hill-tops,' it might be expected in practice that, in view of the multitude of the 'hill-tops' acted upon simultaneously, a considerable rise in temperature might be anticipated. This particular theory seems to be based on the assumption that the small amount of energy involved is transmitted into the glass through an extremely minute area. That the area is never extremely small can be observed by carrying out the operation of polishing under the microscope, the action being viewed through the specimen. Within a second or two the area can be extended from about 2 per cent. to 5 per cent.; in about four minutes the area is about 95 per cent. These results are for a hard pitch polisher. It is remarkable how quickly the pool-like areas spring into view, and an observer will certainly be impressed with the perfection of these areas; there is no appearance of any intermediate stage suggestive of progressive abrasion.

When the whole area is optically polished, can it be contended that the energy is sufficient to maintain in a state of thermol fusion the whole extent of the surface, however thin the layer may be? It is necessary to assume that the load is at any one moment carried by a small number of very minute elements, but the test plate applied to an optically polished surface does not disclose any irregularities sufficiently great to penetrate the film of whatever it may be that exists between the surfaces.

The Nodes at the Reduction Division in Bivalents of Hyacinthus.

IN the grasshoppers and some other animals, nodes have been demonstrated in the bivalents, at the late prophase, by Sutton, McClung, Robertson, Wenrich, Janssens, etc. One of the Orthoptera, *Chortophaga* sp., has eleven bivalents and one univalent (X chromosome) at the late prophase of the maturation divisions in the spermatocytes. These are well shown in iron-acetocarmine preparations. The writer found that the six largest bivalents showed 23 cases with one node to 19 with two nodes. The smallest five bivalents had only one node each. At each node it was obvious, as had been previously demonstrated by others, that one chromatid from each homologue seemed to pass to the other side, while the other chromatid remained on the same side.

In *Hyacinthus orientalis*, where there are eight bivalents at the reduction metaphase, the four largest showed one or two nodes, while the four small ones had only one node. Out of 116 examples of the four largest bivalents, 62 had one node and 54 had two nodes. Examination of these nodes showed that one chromatid appeared to pass obliquely across to the other side, while the other chromatid remained on the same side. Also, as in Chortophaga, the planes of the V or ring-shaped portions on different sides of a node were more or less at right angles.

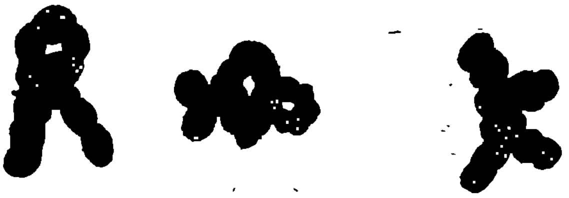

Fig. 1.—Bivalent chromosomes in Hyacinthus.

The best working hypothesis for these cases seems to be segmental interchange between the chromosomes (crossing-over between genes). Crossing-over is known to occur in some monocotyledons, such as Zea. In chromosome I of Drosophila, if we calculate the number of nodes which should be seen in the prophases of the maturation divisions of the ova, to correspond with the determined proportions of no, single, and double crossing-over determined by breeding experiments, we find that the results are not far from those given by Chortophaga and Hyacinthus.

Fig. 1 shows three bivalents of Hyacinthus, the central one having two nodes and the other two one node.

Magnetic Double Refraction.

The action of a strong magnetic field in causing a liquid to become birefringent for light rays transverse to the field was first observed by Cotton and Mouton in nitrobenzene, and was later detected and measured by the same authors in many other carbon compounds of the aromatic series and in some inorganic liquids (*Annales de Physique*, 28, 209-243; 1913). In a recent paper (C. V. Raman and K. S. Krishnan, *Proc. Roy. Soc.*, A, Jan. 1927) it has been shown that the large value of the Cotton-Mouton constant in aromatic compounds indicates that the benzene ring, which is known from observations on light-scattering to be optically anisotropic, has also a very pronounced magnetic anisotropy. Observations on light-scattering in carbon compounds of the aliphatic series indicate that the molecules of these substances are optically anisotropic to an extent which, though smaller than in the aromatic series, is yet very marked (K. S. Krishnan, *Phil. Mag.*, 50, 697; 1925). It accordingly seemed very probable that the compounds of the aliphatic series should also exhibit magnetic anisotropy and give a measurable double-refraction in strong magnetic fields.

As Cotton and Mouton did not in their papers report any observable magnetic double refraction in carbon compounds of the aliphatic series except in some isolated cases, we decided to make a systematic re-examination of the subject. A large electromagnet capable of giving 25,000 gauss in a column of liquid 32 cm. long was available to us. By securing the most favourable optical conditions and taking careful precautions to eliminate any disturbance from the Faraday effect or suspended colloidal particles, we have succeeded in definitely establishing the existence of magnetic birefringence in every one of the liquids examined, the list including many hydrocarbons, alcohols, ethers, and esters belonging to the aliphatic series. New pole-pieces are now in course of construction for our electromagnet, with which we hope to reach a field of 40,000 gauss in a liquid column of the same length and to make an extended series of quantitative measurements of magnetic birefringence. There is good reason to believe that such measurements will prove of value in elucidating problems of molecular structure.

An Important Virus Disease of *Lilium longiflorum* and its Varieties.

In the course of work on the diseases of lilies I have shown by means of controlled experiments that an important disease occurring on *Lilium longiflorum* Thunberg and its well-known varieties of commerce, 'Lilium giganteum' (*L. longiflorum* var. *takesima* Duchartre), 'Lilium formosum' (*L. longiflorum* var. *insulare* Hort. apud Mallett), and 'Lilium Harrisii' (*L. longiflorum* var. *eximium* Baker), belongs to the group of filterable virus diseases and is transmitted by the aphid *Aphis lilii* Takahashi (very close to *A. gossypii* Glov.). The identification of the insect was made by Dr. F. V. Theobald.

The symptoms are a marked downward curling and slightly chlorotic appearance of the leaves. Affected bulbs produce only a flattened rosette, hence the name 'yellow flat' given to the disease.

The disease occurs commonly among bulbs of oriental origin. Rigid government inspection has reduced its incidence in the Bermuda lily fields of 'Lilium Harrisii' to a practically negligible quantity.

Details will be published in due course.

Salaries of University Lecturers.

Prof. H. E. Armstrong's recent reference in Nature (Mar. 19, p. 432) to the salary attached to a lectureship in organic chemistry in the University of Sydney may create misapprehension unless it is pointed out that the general scale for lecturers in all subjects at Sydney is £350, rising by yearly increments of £40 to a maximum of £700 per annum. There is little doubt that the conditions for lecturers at Sydney are distinctly more favourable than those prevailing in many, if not most, of the universities of Great Britain.

Lister's Contribution to Preventive Medicine.

By Dr. C. J. Martin, F.R.S.

LISTER was one of the greatest discoverers in the realm of preventive medicine. His direct contribution equalled in usefulness that ever made by one man; for the antiseptic system of treating wounds relieved mankind from most of the danger and suffering attendant upon surgical operations and permitted the art of surgery to advance to unimagined achievements. His indirect contribution was great and far reaching, but is less easy of assessment.

The obliteration of wound infection which followed the successful practice of antisepsis was an enormous stimulus to research into the causation of infectious diseases generally. These researches received every encouragement from Lister, because he, like Pasteur, was convinced that infectious diseases would be found to depend upon the invasion of the body by the lower world of microbes. From 1851, when he was a house surgeon at University College Hospital, his attention had been focussed upon the causation of inflammation, suppuration, fever, and constitutional disturbance, which at that time almost invariably followed surgical operations. That suppuration was not inevitable was clear, because sometimes wounds healed without it, the edges uniting firmly together in a comparatively short time without any bodily illness. After many fruitless attempts to comprehend the process and causation of suppuration, Lister concluded that it would be wise to attack the problem from the beginning and to study the phenomena of inflammation occasioned in the simplest way. To this end he applied hot water and various chemical irritants to a minute portion of the web of a frog's foot and watched under the microscope the effect upon the blood-vessels and surrounding tissues.

Lister's paper on the early stage of inflammation, published in the *Philosophical Transactions* in 1858, is now classical. In it he showed that inflammation was a reaction of the tissues to a noxious stimulus from without. The problem was: When a wound became inflamed, what was the noxious stimulus? This question was ever present in his mind, but no answer was forthcoming, until in 1865 a scientific colleague directed his attention to Pasteur's studies on fermentation and putrefaction. The full significance of Pasteur's observations was immediately apparent to Lister, as his mind was prepared by his previous experimental work. Infection of wounds by germs, and the action upon the tissues of the products produced by them, would supply the cause he was looking for. Were all these untoward phenomena due to the putrefaction of the liquids exuded by the injured tissues? This inference was tested by ingenious experiments and its accuracy was proved, to the lasting benefit of mankind. It should be emphasised that Lister's discovery of the *nature* of wound diseases was one of the great steps in the progress of preventive medicine, and antedated by fifteen years the proof that any particular microbe was indeed the cause of disease.

At this time (1865) the enlightened medical world had grasped that Pasteur's discovery that particular fermentations were produced by specific microbes indicated the possible nature of the various *contagia viva* responsible for disease. It was appreciated that diseases bred true, as dogs and cats bred true, and that they did not arrive *de novo*, although their ultimate origin was as mysterious as the origin of species of higher animals or plants. The real nature of the *contagia* was pure guesswork.

The success of Lister's treatment of wounds was a powerful stimulus to the study of the cause of infectious diseases, but, occupied with the development of his antiseptic system of surgery, he could take little part in these researches. Nevertheless, in the intervals of a busy life, he did find time for bacteriological investigations of a fundamental character.

This new realm of scientific discovery yet lacked appropriate methods, and Lister had to forge his tools as required. He carried out these early researches in his back parlour. Their importance and the ingenuity of the methods he devised are dealt with in their proper perspective by Prof. Bulloch in another article in this week's issue of Nature.

For fifteen years Lister was the principal representative and exponent in Great Britain of the new knowledge, bit by bit unfolded, of the relation of micro-organisms to disease. As his preoccupations increased with his renown, his personal contributions to bacteriological research, perforce, diminished, but the good effect of his encouragement increased.

Whenever the application of bacteriological discoveries to the public health was in question, Lister always took a prominent part. He was president of the Bacteriological Section of the International Congress of Hygiene in 1881, when Koch demonstrated his newly discovered methods of cultivation upon solid media and isolation of different bacteria. In 1890, Koch introduced tuberculin for the treatment of tuberculous infections. Lister, who had a profound respect for Koch, arranged for a thorough trial of the method in his wards at King's College Hospital. Unfortunately, the results, though encouraging at first, proved disappointing.

At the second Tuberculosis Congress in 1901, Lister was in the chair when Koch communicated the results of his experiments upon human and bovine tubercle which had led him to the conclusion that human and bovine tuberculosis were two distinct diseases and that there was no danger for human beings from the consumption of milk or meat from tuberculous cattle. Lister very courteously, but nevertheless trenchantly, criticised Koch's conclusions, pointing out that although the evidence adduced by Koch to show that human tuberculosis could not be communicated to bovines seemed convincing, his reasons for supposing the reciprocal process to be unusual were far less satisfying. In view of Koch's pre-eminence as a bacteriologist and considering the importance of the question, the Congress moved for the appointment of a Royal Commission of inquiry. This suggestion was adopted by the Government. Lister was not a member of the Commission, but he took an active interest in its labours, and when it reported in 1911, it completely justified the criticisms made by him ten years before.

Another enterprise in the interest of preventive medicine which had Lister's sympathy and active support from its inception, was the foundation in England of an institute for the study of the causation and prevention of disease. The origin of the Lister Institute, as it is now called, was as follows. On July 1, 1889, a meeting was held at the Mansion House, London, for the purpose of taking steps to present M. Pasteur with a grateful acknowledgment from Great Britain of his gratuitous kindness in Paris to more than two hundred British patients who had been bitten by rabid animals. The acknowledgment took the form of a donation of £2000 to M. Pasteur for the use of the Institut Pasteur in Paris. At the same time the committee realised the want in the United Kingdom of an institute similar in character and purpose to the Institut Pasteur in Paris, or to the Hygienic Institute in Berlin, and others, established on the Continent for scientific research into the causation and prevention of the various infective diseases of men and animals.

With the idea of meeting this need the British Institute of Preventive Medicine was incorporated on July 25, 1891, and the objects of the Institute were set forth in a Memorandum of Association, namely :

(*a*) To study, investigate, discover, and improve the means of preventing and curing infective diseases of man and animals ; and to provide a place where research may be carried on for the purposes aforesaid.

(*b*) To provide instruction and education in preventive medicine to medical officers of health, medical practitioners, veterinary surgeons, and advanced students.

(*c*) To prepare and to supply to those requiring them such special protective and curative materials as have been already found, or shall in future be found, of value in the prevention and treatment of infective diseases.

(*d*) To treat persons suffering with infective diseases or threatened with them, in buildings of the Institute or elsewhere.

(*e*) With a view to effecting these objects, to provide laboratories, to appoint a scientific staff, to institute lectures and demonstrations, to issue publications of the transactions of the Institute, and to found a library.

Lister succeeded the Lord Mayor as chairman of the committee after its first meeting, and was the first chairman of the council of the British Institute of Preventive Medicine. Among his colleagues were Roscoe, Huxley, Ray Lankester, Burdon Sanderson, Horsley, Cheyne, and Sir Andrew Clark. Lister was a regular attendant at the meetings of the council for many years and took the most active part in the management of the Institute. The office of chairman of the council was for a while no sinecure, and the direction of the new Institute was an anxious task. During its early years it had great financial difficulties to contend with, and on more than one occasion its continued existence was almost despaired of. It was only by means of the enthusiasm and careful guidance of its council and the self-sacrifice of the small body of scientific men which composed its staff that it did not succumb to inanition.

It was also unfortunate in changing its birth name more frequently than is good for a young institution. In 1898 it became the Jenner Institute of Preventive Medicine in order to receive the donation of a sum of money collected to perpetuate the memory of Edward Jenner and his work. Afterwards it was found that a trading firm possessed the prior legal claim to this title, and a further change of designation being necessitated, it was decided to associate the Institute in future with the honoured name of its chairman. It thus, in 1903, became the Lister Institute of Preventive Medicine.

In the meantime the financial stresses which threatened the collapse of the Institute had been considerably relieved by substantial donations from the Berridge Trustees, the Grocers' Company, and a number of public-spirited men. The Duke of Westminster having granted, on terms which meant a large personal contribution, a fine site facing the Thames at Chelsea Gardens, the council proceeded to build one-half of the present headquarters of the Institute. These were opened in 1897.

The permanent income of the Institute was not, however, adequate to the requirements and capabilities of the enlarged establishment, until towards the end of 1898 it received, for the encouragement of research into the cause and treatment of disease, a most generous endowment of a quarter of a million sterling from Lord Iveagh. This endowment enabled the governing body to extend greatly the usefulness of the Institute and to increase the —up to that time—very inadequate staff

The development of serum therapeutics in 1894 attracted general interest in preventive medicine. A few years previously Behring had discovered that by accustoming an animal to small but progressively increasing doses of tetanus poison, the serum of such an animal possessed the property of neutralising considerable quantities of the poison. This discovery was amplified and put to practical use for the treatment of diphtheria by Roux and Ehrlich, and rapidly established itself as the only rational and effective treatment for this disease.

The preparation of antitoxic sera was at once taken up by the Institute. Some temporary premises near London where horses could be accommodated were acquired, and as soon as the value of the remedy was established the council purchased a freehold property near Elstree, Hertfordshire, where a complete equipment for the production of anti-toxic sera and for research into serum therapeutics was installed.

Since then the activities of the Institute have increased considerably, but two of the objects for which the Institute was founded, the education of medical officers of health and the treatment of patients, have been discontinued. Elementary education in bacteriology was soon afterwards adequately provided for by the medical schools, and the prophylactic treatment for hydrophobia, which was the particular treatment in view, was no longer required owing to the freedom of the British Isles from rabies.

The advantages which the Institute enjoyed from its association with Lister were, in the earlier days of its history, by no means confined to his guidance as chairman of its council. To the scientific staff he was always a colleague. Whatever the nature of the problem they were occupied with, they were sure of his sympathy, and his knowledge and critical insight were ever at the disposal of the humblest worker. During the latter years of his life, although no longer able to take an active part in directing its affairs, he did not cease to take a keen interest in the welfare of the institution he had been largely instrumental in founding, and he manifested his confidence in its continued usefulness by making it joint beneficiary with the Royal Society under his will.

Some Aspects of Lister's Scientific Work.

By Prof. William Bulloch, F.R.S.

My qualifications to write on certain aspects of Lister's scientific work rest on an acquaintance with his published writings. I have studied these critically by themselves and in relation to the writings on the same subjects by his contemporaries. For more than ten years I also had the great privilege of knowing Lord Lister in a manner which, considering the great disparity of our positions, I may say was almost intimate. As bacteriologist to the British Institute of Preventive Medicine I had to visit him as chairman almost weekly, to keep him in touch with the progress of the work in the antitoxin department. Even after I left the service of the Institute he frequently asked me to call upon him in connexion with scientific work in which he was interested. In this way I was a great deal in his company and, among the younger men of that time, probably saw more of him than any one else.

When I first knew Lord Lister he was sixty-eight, and I last saw him in 1909 when he was eighty-two years of age. Both then and since he impressed me as a great personality. He was deeply interested in all advances of medical knowledge and, although leading a very busy life, he strove to keep abreast of bacteriological literature, which was then pouring forth in an unbroken stream. I read through with him most of the complicated papers of Ehrlich and Bordet on hæmolysis. During the reading he would make many suggestions or criticisms which might clear up doubtful points. Finished with the work in hand, he would recur to his own work of early days and indicate the difficulties he had had and how he had overcome them. In a conversation we had on Oct. 23, 1905, he said to me—I wrote it down at the time: "If my works are read when I am gone, my papers on the pigmentary changes in the frog and on the early stages of inflammation will be the ones most highly thought of." These were not the mumblings of senility, for he was then intellectually clear and alert. I took it to mean that he wished to be considered as a scientist rather than a surgical craftsman.

In estimating Lister's scientific work it is essential to remember that he had no properly equipped laboratory as we understand the term to-day. There were none such, or but few at the time. His laboratory was his study in his private home, and perhaps the best of his scientific work was that done in 11 Rutland Street, Edinburgh, during his first stay in the northern capital. His principal work on antiseptics was done during the Glasgow period, while his bacteriological work was begun and largely completed in his second Edinburgh period when he resided at 9 Charlotte Square.

The hours for Lister's scientific work were early in the morning and far into the night following a harassing day of active surgical work in private practice, or in the wards, operating theatre, and class-rooms of the Edinburgh Infirmary. He performed all his appointed duties in a most conscientious way, and he undertook his experimental work so that he might speak with first-hand knowledge on the themes which he had to teach. Many of the problems he felt impelled to investigate were obscure and complicated, but of the greatest practical importance. Some were not capable of solution then, and others have not yet been definitively cleared up. I refer in particular to his work on the coagulation of the blood and on the early stages of inflammation.

The coagulation of the blood has at all times excited wonderment, and the theories to explain it have been innumerable and are still being brought to light. In Great Britain notable advances were made in the eighteenth century by William Hewson, who unfortunately died of sepsis from a wound before he was thirty-five. In his short life he made, however, many discoveries. He proved that the red corpuscles were biconcave discs; he described their arrangement in masses like piles of money, an observation extended in 1827 by Lord Lister's father in association with Dr. Thomas Hodgkin. Hewson also clearly noted the existence of the white blood corpuscles and performed a large number of experiments on blood coagulation, although he never quite cleared up the mystery of its nature. His successors in the nineteenth century were not more happy. Coagulation of the blood was early studied by Lister. The problem was constantly before him in connexion with intravascular clotting and the occurrence of putrefaction and secondary hæmorrhage in wounds. The prevailing theory was that of B. W. Richardson, and referred the clotting to the escape of ammonia, which was believed to hold the coagulative elements, normally, in solution.

In a long series of masterly experiments Lister showed that this ammonia theory was untenable. He clearly saw the need of separating the nature of coagulation from the cause, and while baffled with the former he revealed by his experiments that the latter—the cause of coagulation—is really due to the influence exerted on the blood by the contact, even momentarily, of ordinary matter of some kind. He considered that this contact brings about a reaction between the solid and fluid constituents of the blood so that the corpuscles imparted to the *liquor sanguinea* the disposition to clot. As regards the cause of blood coagulation, it cannot be said that we have materially advanced during the seventy years since the publication of Lister's paper.

Another basic pathological process which Lister examined was inflammation. The extraordinary changes which we call inflammation have at all times attracted attention, and the theories intended to explain it constitute a large part of the history of medical doctrines. What is the real nature of the process which we call inflammatory and which results from the application of an *irritamentum* to the body? When Lister began his studies on inflammation, great advances on the older doctrines had already taken place. In England particularly, the science of experimental pathology was in process of rapid growth. The older pathological anatomy so ably created by Morgagni was developed well by the French, among whom the names of Bayle, Portal, Laennec, Bretonneau, Chomel, and Cruveilhier will be brought to mind. Students went from Great Britain to study pathological science in France.

At the beginning of the nineteenth century Edinburgh was a great nursery of medical talent, and many of her graduates migrated across the border to attain fame in the arenas of the south. We all remember with pride the names of Charles Bell, Richard Bright, Thomas Addison, Thomas Hodgkin, C. J. B. Williams, Marshall Hall, William Sharpey, and the peculiarly able if eccentric Wharton Jones. Their work was advanced by the experimental work of Augustus Volnay Waller and of the little-known but successful worker William Addison. Lister had both Sharpey and Wharton Jones for his teachers. The margination of the leucocytes in the inflamed vessels was taught by C. J. B. Williams, and W. Addison about 1842 and Waller (1846) rediscovered the process of emigration of the leucocytes, which had been previously described by Dutrochet in 1827. Wharton Jones summed up in most critical fashion all the work down to 1846, and himself gained the Astley Cooper prize in 1850 for his splendid essay on the phenomena of inflammation.

When, therefore, Lister began to work at the pathology of inflammation he was traversing ground already trodden. He realised, however, that much that had been done concerned the later stages of the process, whereas the real essence of inflammation was most likely to be found by the study of the earliest stages. He worked chiefly with the frog's web and the bat's wing, and took elaborate precautions that at first the parts should be in a perfectly normal condition. By the application of irritants he then passed to the study of what was pathological. Among the phenomena which he particularly investigated may be mentioned the aggregation of the red blood corpuscles, their increased adhesiveness, and the structure of the arterioles and capillaries. He found that the capillaries alter in calibre, but referred the variation to something inherent in their elasticity. While admitting the phenomenon of contractility in the capillaries, modern workers have not accepted his explanation. Lister regarded irritants as acting in a twofold manner. The primary effect was a dilatation of the vessels brought about by the influence of the nervous system and not limited to the *locus* of the irritant. The secondary effect, on the other hand, was the direct result of the irritant acting on the tissues in consequence of which the blood becomes altered physically. The red discs become more adhesive, they accumulate in masses and may bring about the condition of stasis.

Strange to say, Lister made no reference to diapedesis of leucocytes, and probably missed it altogether. Waller's discovery of 1846 had left so little impress at the time that when diapedesis was described in detail in 1867 by Cohnheim, it was regarded as something altogether new. Previous to Lister's work, the advanced changes in inflammation had been observed and very fully described by Wharton Jones, but it is to Lister's credit that he examined it from a new viewpoint and discussed its significance more than his predecessors had done. He was, however, surpassed by Cohnheim in his classical work in 1867.

When Lister embarked on his extended researches on wound complications and the cause of suppuration, his experimental inquiries on blood and inflammation were a great help to him. He was groping unaided for the causes of suppuration, but light was beginning to peer through the darkness. This was early in his Glasgow term. In 1865 his attention was directed by a colleague to the work which had been done on fermentation and putrefaction by Pasteur, and this came to him as a revelation. Almost immediately he grasped the significance of the Frenchman's work for surgery. Ten years later (1875) he specifically tells us that the work of Pasteur "long since made me a convert to the germ theory, and it was on the basis of that theory that I founded the antiseptic treatment of wounds in surgery."

Although Lister constantly stated his indebtedness to Pasteur, it is, I think, a vulgar error to regard him as a mere copyist of his great French contemporary. So early as 1861, and before he knew Pasteur's results, he was getting near the truth about suppuration, and later on he advanced beyond the point where Pasteur had led him. No doubt Pasteur revealed to him in a more concrete form what he had dimly foreseen himself, and from then onwards he was ardent in the pursuit of bacteriology. The time would be the early 'seventies, when the study of microbes had not emerged as a definite science. There were at the time two conflicting views. One of these, supported by Ferdinand Cohn, the botanist of Breslau, held that bacteria, like other plants, had a constancy of form which rendered them capable of division into genera and species. According to the other view, there was no morphological constancy, but rather a pleomorphism, whereby one and the same bacterium could assume different forms. If this were true, attempts to cultivate or to separate them on morphological grounds were doomed to failure.

In his earliest work on the subject in 1873, Lister's observations led him to support the pleomorphic theory, and it will now be admitted that he suffered shipwreck upon it when he stated that Ehrenberg's and Cohn's morphological classification was "entirely untrustworthy." Lister's mistake was one which at the time was made by a great many others and tends to indicate the extraordinary pitfalls which beset the path of the earlier bacteriologists. In his life of Lister, Godlee has published an interesting correspondence which passed between Lister and Pasteur on the subject of change of form among bacteria. Pasteur clearly saw where Lister had erred and advised him to repeat his observations with additional technical precautions. This Lister did, and profiting by his new experience he became one of the foremost bacteriological technicians of his time. So imbued was he with the spirit of high ideals that instead of covering up his tracks he handsomely withdrew his error. "Next to the promulgation of truth," he said, "the best thing I can conceive that a man can do is the recantation of a published error." This sentiment was almost identical with that given to us nearly two thousand years ago by Celsus, who, however, added that such a confession is suited only to a great genius whose splendour is such as to survive the sacrifice, especially in the performance of a task which is to be handed down for the benefit of posterity as a beacon of truth to warn them against similar errors.

From the theory of Cohn and Pasteur it was to be presumed that bacteria might in some way be separated from each other and cultivated in a pure state. The great mycologist, Brefeld, had emphasised the importance of raising such pure strains or cultures from one single germ or cell of a fungus. Following in his wake, Lister was the first to isolate a pure culture of a bacterium. By perfect bacteriological technique involving a complete understanding of the problem, he succeeded in isolating a pure culture of a microbe, *Bacterium lactis*, which is the cause of lactic-acid fermentation in milk. He grew this microbe in sterile milk and raised a pure strain, constant morphologically and physiologically, from a single cell by a series of dilutions carried out with an ingeniously constructed syringe of his own invention. No one can deprive Lister of the merit of having first isolated bacteria in pure culture outside the body. The year was 1877. Lister also introduced the methods of hot-air sterilisation which are in vogue today. His long paper on lactic fermentation is a classic, and a model of what a scientific research should be.

Like Pasteur, Lister had the supreme faculty of seeing as if by instinct the exact experiment needed to clear up a point of doubt. All his scientific work bears witness to this, but I may refer to one other instance of it. In two or three experiments which he did on the fate of catgut implanted in the tissues, he got out all the essential facts in 1869, and later attempts of others in more than three hundred papers down to 1927 have, literally speaking, neither added to nor subtracted from anything which he taught us sixty years ago. He was a master of the experimental method—a rare and precious gift which, the Abbate Spallanzani truly said, "has always been confined and always will be confined to the few."

Obituary.

Prof. Carl Runge.

With the death, on Jan. 3, 1927, of Prof. Carl Runge, of the University of Göttingen, in his seventy-first year, there has passed away an eminent mathematician and a friend to several generations of English-speaking students in Germany.

Runge, whose mother was English, was born in Bremen in 1856 and was educated at Munich and Berlin. In 1886 he was called to the Technical High School at Hanover, where he remained until 1904, when he moved to a professorship at Göttingen in response to an invitation from Klein. Coming in early life under the dominating influence of Weierstrass and Kronecker, it was not unnatural that his first work should be in the field of function theory and algebra, but the urge towards the practical, which directed much of his later work, was soon apparent. Many of his lectures at Columbia University, where he went as an exchange professor in 1909–10, deal with this aspect. At Hanover, as a mathematician in an engineering environment, he had perforce to devise ways and means of adapting methods of mathematical analysis to the practical. Many of his numerical and graphical methods, numerical integration, solution of differential equations and Fourier analysis are now commonplace in engineering training. In this respect his influence on German teaching methods was rather similar to that of Perry in Great Britain. Wherever possible he played an active part in actual practical work, as for example when he assisted in a large geodetic survey, and his appreciation of real problems reflected itself in his teaching and in his theoretical research. His many contributions to the fields of technical mechanics and aerodynamics are evidence of this.

Runge was, however, something more than an engineer, a mathematician, and a teacher. Among experimental physicists he is known for his fundamental work in collaboration with H. Kayser on spectral series, and his work in this field ranks him among those who have laid the experimental basis of quantum mechanics. He examined the spark and flame spectrum of radium. He investigated the magnetic resolution of spectrum lines, and showed that the apparently complex separation may be expressed as simple fractions of that of the normal Zeeman triplet. With Paschen he devised a concave grating mounting that has been adopted in many laboratories. He was pre-eminently one of those all too few men of science who could turn his mind profitably to any field of scientific inquiry with the certainty of producing creative work. Educationally, in Germany his influence was to give a practical orientation to the theorist, and a theoretical outlook to the practical man. To English-speaking students in Göttingen he was undoubtedly the most English of the professoriat, both in appearance and in mental outlook, and he spoke the language fluently. His son was killed early in the War. H. L.

Sir Charles Walston.

We regret to record the death of Sir Charles Walston, the well-known Cambridge archæologist. Charles Walston (formerly Waldstein, the change in spelling having been effected in 1918 at the end of the War) was born in New York of parents of Jewish stock on Mar. 30, 1856. He was educated at Columbia and Heidelberg Universities, and went to Cambridge at the age of twenty-four at the invitation of Henry Bradshaw and Henry Sidgwick as a lecturer in classical archæology.

A brilliant and stimulating teacher, with abundant vitality and unbounded enthusiasm, Walston's qualities as an archæologist and his keen perception of the details of artistic style early won him wide recognition as an authority, and at the same time did much to stimulate the study of ancient sculpture in Cambridge. In 1894 he was elected a fellow of King's College. He held various university posts; among them the readership in classical archæology, the directorship of the Fitz-William Museum, the Slade professorship from 1895 until 1901 and from 1904 until 1911. From 1889 until 1893 he was director of the American School of Archæology at Athens, where he conducted important excavations at Platæa, Eretria, and on the Heraion at Argos (1892–1895). After the expiration of his term as director he retained his professorship at the School until 1896.

Walston's more important publications on archæological and artistic subjects were: "Essays on the Art of Phidias," 1885, "The Work of Ruskin," 1894, "The Study of Art in Universities," 1895; "The Argive Heraion," 1902; "Art in the Nineteenth Century," 1903; "Herculaneum, Past, Present, and Future," 1908; "Greek Sculpture and Modern Art," 1914; and, quite recently, "Alcamenes and the Establishment of the Classical Type in Greek Art," a work of considerable importance and of broad and comprehensive learning, in which he maintained that throughout the early periods up till the fifth century B.C. one facial type, which he called the Minoan, prevailed in Greek art, differing essentially from the classical type. Walston's interests were by no means confined to his special study, and he wrote on a wide variety of subjects of public interest and, during the War, made a number of contributions to the literature of the time, in which he expounded and interpreted national and social tendencies. In this field his most valuable contribution was "Aristodemocracy," published in 1916, while in "Harmonism and Conscious Evolution," 1922, he set out his theory that the æsthetic principle lies at the root of science, morality, and all man's other activities.

Dr. C. Da Fano.

Dr. C. Da Fano, reader in histology, King's College, University of London, died with unexpected suddenness at his residence at Campden Hill on Mar. 14, in his forty-eighth year. By his death medical science in Great Britain loses one of the ablest exponents of histology.

Dr. Da Fano was the third son of Commendatore Alessandro Da Fano. He received his early training in histology in Golgi's Institute of Histology and General Pathology at the University of Pavia, where he graduated M.D. in 1905 and later (1912) became *Libero Docente* in morbid anatomy. He obtained a travelling fellowship at Milan and worked in Ziehen's neurological clinic, University of Berlin, in 1908, and in the following year with Dr. Bashford at the Imperial Cancer Research Fund, London. After a period of work at Groningen he returned to the University of Milan as vice-director of the Pathological Institute. From 1915 until 1918 he served as captain in the Italian medical corps on the Italian front. In 1918 he went to King's College, University of London, as lecturer in histology, and in 1922 was given the title of reader in histology in the University.

Dr. Da Fano specialised in the histology of the central nervous system. His advanced lectures on that subject attracted large audiences, and the histological specimens by which these lectures were illustrated formed a complete and noteworthy collection. His researches, published in a series of about sixty papers in various journals, were mainly concerned with the Golgi apparatus in cells and the special lesions of the nervous system in such affections as encephalitis lethargica. He had a very extensive knowledge of foreign languages, and he generously devoted a considerable portion of his time to acting as one of the editors of *Physiological Abstracts*. In 1915 he married Miss Dorothea Landau, and leaves a son and daughter.

News and Views.

In an article appearing in the supplement to the present issue of Nature, Sir Joseph Larmor gives a novel interpretation of the local space and time of relativity theory as the absolute space and time of Newtonian dynamics and astronomy. This is clearly not the place to attempt a detailed critical analysis of this important paper, but it may be permissible to summarise a few of the salient arguments. The correlation of past and present astronomical research, as well as the absolute character of atoms, evidenced by spectroscopic research, wheresoever and whensoever they are found, demand absolute time. The welding of local frames of inertia into one coherent fourfold is the business of relativity; the mutual dynamics of masses existing in each local frame proceeds independently by Newtonian principles. The mathematical development is effected by means of the Principle of Least Action, modified to suit the requirements of electrodynamics and relativity and limited as to form by the necessity of conforming to the postulate of invariance. The requisite formulation of a compound Action-density is first minimised as regards its distribution with reference to variation of structure of the fourfold pseudospace, giving structural differential equations of that fourfold, and then by partial integration the Action is reduced to line integrals along the tracks of the atoms in the fourfold.

By a further minimising of the Action in its new form, Sir Joseph obtains the expression, suitable to the fourfold, of the dynamical interaction of the atoms. An essential feature is that the track of the atom is not treated as an isolated geodesic, determined by the gravitational warping of the pseudospace, of which it is both partial cause and effect, but is connected with other tracks through mutual terms in their potential energy, which are shared between the interacting atoms. In an earlier paper by Sir Joseph (*Phil. Mag.*, S. 6, vol. 45, p. 243, 1923) this sharing of potential energy led to a reduction of Einstein's gravitational constant to one-half of its usual value, because there the time t of the invariant space-time interval of relativity theory was as usual identified with astronomical time. In the article now under discussion, this untoward result is avoided by identifying the local time T, *i.e.* the invariant time t now corrected for convection by means of the Lorentz transformation, with the absolute time of Newtonian dynamics and astronomy. This procedure leads to Einstein's values of the displacement of spectral lines and of the gravitational deflexion of rays of light, but apparently not to his result for the progressions of planetary perihelia, a conclusion regarded by Sir Joseph as not unsatisfactory in view of the uncertainty of the progression of the perihelion of Mercury, as shown in recent astronomical discussions. Moreover, it leads to the proper relation between electric mass and energy relative to the fourfold, a relation which is not substantiated at all except on the present Newtonian scheme.

April 5 was the centenary of the birth of Lister, physiologist, pathologist, and the 'father of modern surgery,' and elsewhere in this issue Dr. C. J. Martin and Prof. W. Bulloch describe some aspects of his life and work. Celebrations of the centenary commenced in London on April 4, when H.M. The King received delegates from learned societies, universities, and medical societies in Great Britain, from the Dominions and many foreign countries, who are attending the ceremonies arranged by a joint committee of the Royal Society, the Royal Colleges of Physicians and Surgeons, the Royal Society of Medicine, the British Medical Association, and other bodies. Sir Ernest Rutherford, president of the Royal Society, presented an address to the King, to which His Majesty replied, expressing the hope that the gathering of scientific workers for the centenary celebrations would "strengthen the co-operation of all nations in the accumulation of scientific knowledge for the common benefit of the human race." Personal memories of Lister were given by Sir St. Clair Thomson in an address before the Royal Society of Medicine in the evening, and by Sir Watson Cheyne and Sir George Lenthal Cheatle at a meeting in the afternoon of the Listerian Society. On April 5, the official delegates of centenary celebrations were received by the Prime Minister at the house of the British Medical Association, and on the following day a memorial service was held at Westminster Abbey. We hope to give an account of the proceedings in an early issue. Centenary celebrations at Glasgow began on April 1; those arranged at Edinburgh will be held concurrently with the annual meeting there in July of the British Medical Association.

The text has been issued of the Destructive Insects and Pests Bill, which was introduced into the House of Commons by Mr. Guinness on Mar. 25. This Bill provides that an order under the Destructive Insects Act, 1877, as amended by the Act of 1907, may enable an authorised inspector of the Ministry of Agriculture to take necessary action with reference to any crop infected with an insect specified in the order as being a destructive insect within the meaning of the principal Act, which has been introduced into Great Britain. The Act provides that such an inspector may remove or destroy, or cause to be removed or destroyed, any crop infected, or any crop by means of which the insect is likely to be spread. The Bill also provides for the payment of compensation in respect of any crop removed or destroyed. Until now, very few introduced pests have gained a footing in Great Britain, but the provisions under the new Bill are timely precautions. A few years ago the Colorado potato beetle became established in the Bordeaux district of France and its eradication now seems scarcely possible. The entry of such a pest into Great Britain would constitute a menace to a crop that suffers to an almost negligible extent from insect pests. Notwithstanding precautions against their admittance, foreign pests may secure a foothold, and the new Bill provides for the necessary action in the event of such an occurrence. The heavy infestation of cherries from some parts of the continent with the cherry fruit fly is another case in point, but happily that insect likewise has not yet become established in Great Britain.

The first statutory general meeting of the British Mosquito Control Institute was held at the Hotel Cecil, London, on Mar. 30, when the council was elected in accordance with the articles of association approved by the Board of Trade, and by which the Institute is registered under the Companies Acts, 1908–1917, as a company limited by guarantee and not having a share capital. Since the anti-mosquito campaign was begun at Hayling Island about seven years ago, it has become increasingly evident that the work so successfully accomplished there is of more than local interest, and that medical officers of health and sanitary inspectors in many parts of Great Britain, as well as abroad, desire to know how to keep mosquitoes under control. The Ministry of Health can only concern itself with these insects as disease carriers, even though in some districts they make life out of doors almost intolerable in certain months of the year. The Natural History Museum is always willing to identify specimens and give general guidance on methods of dealing with them, but neither it nor the Ministry of Health is concerned with actual field operations by which the mosquito nuisance may be reduced or eliminated. This practical knowledge is, however, available at the British Mosquito Control Institute at Hayling, where there is now a substantial building with laboratory, museum, photographic room, and other facilities for the study of all stages of mosquito life and its regulation. The Institute has been vested in trustees by the founder and director, Mr. J. F. Marshall, whose devoted services in solving problems of mosquito control are widely known and appreciated. Membership is open to all who are interested in the subject, and it is hoped that, in due course, sufficient support will be forthcoming from members and public bodies to make the Institute self-supporting and extend its activities. The council includes among its members Sir Ronald Ross, Sir William Simpson, Sir Arthur Shipley, Dr. Andrew Balfour, Major E. E. Austen, Sir James Crichton-Browne, Dr. G. A. K. Marshall, Dr. C. M. Wenyon, and other entomologists familiar with the mosquito pest, and the chairman is Sir Richard Gregory. The address of the Institute is Hayling Island, Hampshire.

Capt. C. W. R. Knight's kinematograph exhibition "Filming the Golden Eagle" should be seen by every one interested in wild life. It began a short season at the Polytechnic Theatre, Regent Street, W.1, on April 2. By means of this excellent film one is enabled to make intimate acquaintance with one of the finest and least common species in the native avifauna of Great Britain. The pictures were taken last year at three different Scottish eyries, and many interesting incidents from the lives both of the young and of the mother bird are shown. In one case, Capt. Knight was even able to follow the young with his camera for some time after they had left the nest and were able to fly. Perhaps the most striking items are the slow-motion pictures of the adult bird in flight: these include photographs of a trained captive eagle catching the lure in mid-air. In addition to various incidental pictures, there are also some short episodes from the lives of other birds, and those of the chaffinch and of the longtailed-tit are particularly good.

A dispatch from Cairo dated Mar. 31, which appeared in the *Times* of the following day, announces the discovery at Saqqara by Mr. Cecil Firth, working for the Department of Antiquities, of a tomb of the Third Dynasty of about 2900 B.C. The tomb, which has a rounded top, is situated on part of the wall about a mile long which surrounds the Step Pyramid. It is thought that it may be the tomb of Imhotep, the architect of the Step Pyramid. An interesting feature of the tomb is the work of low relief on the doors of the underground rooms. Each represents Pharaoh Zoser in the finest artistic style of the period, and although the figures stand out only a millimetre, each muscle is distinctly shown. Twelve magnificent alabaster jars nearly three feet high were found.

Dr. Gann's preliminary account of his explorations during the past winter in British Honduras, which appeared in the *Morning Post* of Mar. 28 and two succeeding days, again provides material of much interest to the student of Central American archæology, although it contains nothing so sensational as his discovery last year of the early dated stele at Chetumal Bay. An unsuccessful search for a bilingual record, which might play the part of a Central American Rosetta Stone, in the first Spanish church at Villa Real, the settlement founded by Davila in 1528, was followed by a visit to a camp on the lagoon On Ha on the northern boundary, where excavations on burial mounds produced evidence of Toltec influence on the Maya in the form of a clay squatting tiger with a human head protruding from its mouth. Northwest from Sao Xan on the Rio Hondo, Dr. Gann discovered great ruins of a temple structure 120 feet high, of which the roofs must originally have been at least 160 feet from the ground. It contained a single chamber 58 ft. long, 18 ft. high, and only 3 ft. wide. Chambers in other buildings were as narrow, or even less in width. The Maya ignorance of the principle of the true arch and their employment of the method of overlapping stones in roofing restricted the width of their buildings to at most 16 ft., but nothing proportionately so narrow as these chambers is known in Central America. Dr. Gann conjectures that they were constructed for ceremonial purposes.

An exceptional opportunity for the comparative study of folk-dances will be offered by the festival to take place at Bayonne on April 27 and 28. It is being organised by the Musée Basque de Bayonne. A team of fourteen dancers of the English Folk Dance Society will take part in the festival and will give two performances, one at the annual ball in aid of the funds of the Musée, and the second on the afternoon of the following day, when the English dancers will dance in alternation with teams from the Basque provinces of La Soule, Labourde, Basse Navarre, and Guipuzcoa. As some of the dances from these provinces, each of which has its own tradition, are of a very primitive type, yet in certain features present resemblances to some English folk-dances, their presentation at the same performance should be highly instructive. It will be remembered that Miss Violet Alford, both in the paper read before the British Association at Oxford last year and later, in the autumn, at the joint meeting of the Royal Anthropological Institute and the English Folk-Dance Society (Nature, Dec. 4, 1926, p. 824) stressed the significance of the *Danse de l'Ours* of Basse Navarre in relation to the meanings of some of the primitive traits in English dances, and she is now engaged in carrying her researches further in the Pyrenees area. The English Folk Dance Society's party, which will include in addition to the dancers any members of the Society and their friends who wish to avail themselves of this opportunity, will leave for Bayonne on April 24.

Mr. J. Allen Howe delivered the Friday evening discourse at the Royal Institution on April 1, taking as his subject "The Stones of London." Situated on a sub-stratum of clay and incoherent gravel, London, from its very beginnings, has had to go beyond its borders for stone. In the fragments of the Roman Wall we have evidence that its builders sought the slopes of Hertfordshire for boulders of hard sarsen stone, the Downs and the Weald of Kent for chalk, ragstone, chert, and firestone; while the local flint gravel was freely used then as now. The Normans introduced the stone from Caen, of which examples may be seen in the Tower, Westminster Abbey, and other buildings. Beer stone from Devon and the somewhat similar Clunch stone, both from the Chalk formation, were much in demand for carving from about the eleventh century; while for columns, beautifully exemplified in the Temple Church, the marble of Purbeck was the favourite material. From the Great Fire of 1666 a new stone era began for London; although many other stones have been and still are employed, Portland stone from that time began to play a dominant part. The majority of London's buildings are now built or faced with limestone, which is readily attacked by the acid-laden town atmosphere, yielding calcium sulphate in the process; this is in itself a cause of further destruction, as the solution soaks into the stone and there crystallises. In the presence of the acid-bearing air the principal cause of unsightly decay is a state of dampness, which may be conditioned by the aspect, the construction, or the design. Continual efforts are being made to discover a preservative that will not impair the appearance of the stone. The least objectionable of these processes, for example, the various silico-fluorides, are liable to prove ineffective after a comparatively short period, and the latest, Dr. Laurie's silicon-ester, is still on trial. The difficulty with all external applications is imperfect penetration with the consequent danger of skin formation.

The annual lecture to the Graduate Section of the Institution of Mechanical Engineers was given by Sir John E. Thornycroft on Mar. 28, his subject being "Torpedo Boats and their Machinery." It is more than sixty years ago that Sir John I. Thornycroft began steam-boat building at Chiswick, and it was his work and that of Sir Alfred Yarrow which made the Thames famous as the home of the high-speed vessel. There is no more fascinating story in engineering than the history of torpedo craft, from the early boats of 30 tons to the destroyers of to-day of more than 2000 tons. The latter have boilers and turbines of more than 40,000 H.P. giving a speed of nearly 40 knots. Turbines have been fitted for twenty years, but in the four-cylinder triple expansion engines of earlier destroyers mechanical engineering of the nineteenth century reached its highest pitch of excellence. The speed at which they ran, the lightness of their construction, and the conditions under which they worked, were all remarkable. Sir John in his lecture gave comparative figures which showed that the machinery of a liner in 1855 weighed more than 600 pounds per horse-power, while in a modern destroyer the corresponding figure is 30 pounds. In the coastal motor boats built during the War and fitted with internal combustion engines, the weight was only 12¼ pounds per horse-power.

At a meeting of the Newcomen Society on Mar. 30, a paper on "Lead Mining and Smelting in West Yorkshire" was read by Dr. A. Raistrick. In the course of his paper Dr. Raistrick traced the history of lead mining in the Yorkshire dales from Roman times down to the present day, giving notes on the method of quarrying the ore, smelting it, and its sale and transport. Lead pigs are in existence bearing the names of Roman emperors, and there is evidence to show that the industry was carried on continuously, practically down to the present time, though to-day little is being done. The cheaper ores from Spain and elsewhere have been the main cause of the decline, but as foreign mines have to go deeper and instal more machinery, the ore will increase in price and thus the Yorkshire mines may again become profitable. The paper contained much of interest to those who study the history of mining.

Purchases during March for the Department of Zoology of the British Museum (Natural History) included a collection of rare land-snails of the genus Nenia from Peru, Bolivia, etc., and a remarkably fine golden eagle from Norway. The Trustees also purchased, for the Department of Geology, seven specimens of an ancient roofed-head amphibian, Protriton, from a new locality in Thuringia. This little salamander-shaped animal is well preserved in a dark oilshale of Lower Permian age; it is one of the Branchiosauria, which owe their name to the indications of gill-arches in the skeletons of immature individuals. A large collection of skulls and heads of African game animals was presented by Major C. H. B.

Grant. These are particularly valuable since they are accompanied by full details of locality, season, and the like; many of them represent species or races that are now in danger of extermination. Among other donations submitted to the Trustees was a small series of fossil-bearing rocks obtained by the Norwegian expedition of 1921 from the palæozoic formations of Novaya Zemlya. A nodule containing a V-shaped burrow, probably formed by a kind of lob-worm, was presented by Dr. S. H. Haughton, who obtained it from the Upper Dwyka shales of the Warmbad District, South West Africa; it suggests that these rocks were formed on a tidal flat. Mr. J. R. T. Regan presented some curious branching structures, probably worm-tubes, found by him in the Totternhoe Stone near Dunstable. Other donations included nummulites from north-west India described by Major L. M. Davies, and type-specimens of shells from a freshwater sandstone of unknown age in the Fiji Islands collected by Dr. Matley.

The completion of a second submarine cable connecting Canada with Australasia is an event of considerable importance. E. S. Heurtly, in an article in the *Electrician* for April 1, gives many interesting details of the work. It involved the laying of two cables, one between Bamfield, on Vancouver Island, and Fanning Island (3466 sea miles) and between Fanning Island and Suva, Fiji Islands, a distance of 2054 sea miles. The original cable, which was laid in 1902, had a working speed of about 75 letters per minute. By using amplifiers, however, its speed has been increased to about 135 letters per minute. The maximum speed on the new northern cable is at least eight times as great as that of the original cable, and the received voltage at Fanning Island is at least five times as high. The great improvement in the traffic-carrying capacity of the two cables is due to the 'loading' of the cables by alloys of nickel-iron, which have a very high permeability for very low magnetising forces. The 'chrome permalloy' used for loading the southern cable has better electrical characteristics than that used on the New York-Azores cable. The original cable has one advantage over the new cables, as duplex working can be used with it. Owing to the difference in times between Europe and Australasia there is little overlapping of the messages going in opposite directions, and consequently this is not a serious drawback to the new cables. Accurate measurements of the time of propagation of the signals between Bamfield and Fanning Island have been made by means of a siphon recorder used with an amplifier and a tuning-fork. The mean of all the results shows that the signal takes 0·67 of a second to travel 3466 miles. When signalling, therefore, at 1000 letters per minute, more than 40 impulses may be in the cable at the same time.

One of the most remarkable of recently constructed tunnels is the Rove tunnel on the new canal between Arles on the Rhone and the port of Marseilles, by the use of which river traffic can avoid the delta or the crossing of the sea between the terminus of the old canal at Port au Bouc and Marseilles. A fully illustrated article on the canal water appears in *La Science Moderne* for February. The Rove tunnel under the Nerthe hills is nearly four and a half miles long. It has a width of 72 feet, of which 13 feet are utilised by the pathways beside the canal. The depth of water is seven feet and there is room for two streams of canal traffic, with a height above the water line of about 43 feet. Apart from through traffic, this canal promises to be of value in the new scheme, now under way, of making the great Étang de Berre, beyond the northern end of the Rove tunnel, a great port, accessible by large vessels from a wide and deep ship canal at Port au Bouc. Around this extensive harbour is ample room for manufacturing sites. Provided the water power of the Rhone and its tributaries is made available, the port of Marseilles may well become a great centre of manufacturing industry.

The magazine of the Geographical Association, on reaching its fourteenth volume, has been named *Geography* in place of the original title *The Geographical Teacher*. The change in name involves no change in policy or scope. It is still to be published three times a year and to be devoted to the interests of teachers, but its general appearance and production have been much improved. In addition to the usual short articles, notes for teachers, and reviews of geographical books, the spring number contains Sir Charles Close's presidential address on "Population and Emigration," in which he makes a statistical study of Empire settlement. In the belief that the Dominions can absorb annually about five per thousand of their total population, he estimates that Great Britain could send overseas about 100,000 emigrants a year apart from the number that go outside the Empire. He gives a total of about 168,000 as the reasonable annual emigration.

No. 4 of the *Quarterly Review of Biology* completes volume 1, and the editors, Profs. Raymond Pearl and R. W. Hegner, are to be congratulated on the success of their initial volume. The trustworthy and readable articles on subjects of current interest and importance in various fields of biology, and the helpful notices of new biological books, have established the reputation of this new *Review* and have made it what its editors intended it to be—useful to the professional biologist, to the worker in other sciences who wishes to maintain his general interest in biological progress, and to the intelligent lay reader. The principal article in this issue (No. 4) is a comparative account by Dr. Adolph H. Schultz of the fœtal growth of man and other primates, which is excellently illustrated by drawings, diagrams, graphs, and tables. The London agents for the journal are Messrs. Baillière, Tindall and Cox, 7 and 8 Henrietta Street, Covent Garden, London, W.C.2.

Dr. P. Chalmers Mitchell will deliver the annual Huxley Memorial Lecture at the Imperial College of Science and Technology, South Kensington, on May 4, taking as his subject "Logic and Law in Biology."

Sir James Berry, president of the Royal Society of Medicine and author of standard works on surgical subjects; Sir H. Walford Davies, professor of music, University College of Wales, Aberystwyth; and Sir Frederick Keeble, formerly Sherardian professor of botany, University of Oxford, and distinguished by his work in pure and applied botany, have been elected members of the Athenæum Club under Rule II., which provides for election by the Committee of "persons of distinguished eminence in science, literature, or the arts, or for public services."

THE annual dinner of the British Science Guild will be held at the Criterion Restaurant, London, on Thursday, May 12. Lord Askwith will preside, and the guests include Sir Alfred Mond, Sir Herbert Samuel, the Hon. W. Ormsby-Gore, Sir William Pope, and Sir Frederick Keeble. Particulars may be obtained from the Secretary, British Science Guild, 6 John Street, Adelphi, W.C.2.

AT the annual general meeting of the Ray Society held on Mar. 24, the following officers were re-elected: *President*, Prof. W. C. McIntosh; *Treasurer*, Sir Sidney F. Harmer; *Secretary*, Dr. W. T. Calman. Dr. G. P. Bidder was elected a vice-president, and Mr. J. Spedan Lewis and Mr. F. Martin Duncan were elected new members of council. It was announced that the Society's issue for 1927 would be the first volume of a "Monograph of British Sea Anemones," by Dr. T. A. Stephenson, which will be illustrated with coloured plates from the author's drawings of the living animals. It is expected that this work will prove unusually attractive as well as of great scientific interest.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant master for mathematics at the Government High School, Nassau, Bahamas—The Board of Education (C. A. (T.)), Whitehall, S.W.1, or The Scottish Education Department (T.), Whitehall, London, S.W.1 (April 11). An assistant pathologist at the Charing Cross Hospital Institute of Pathology—The Secretary of the Institute, 62 Chandos Street, W.C.2 (April 25). Junior assistants in the aerodynamics department of the National Physical Laboratory—The Director, National Physical Laboratory, Teddington (April 30). A lecturer in geography at Armstrong College—The Registrar, Armstrong College, Newcastle-upon-Tyne (May 7). A professor of agriculture at Armstrong College—The Registrar, Armstrong College, Newcastle-upon-Tyne (May 20). An assistant in the Dominion Museum, Wellington, New Zealand—The High Commissioner for New Zealand, 415 Strand, W.C.2 (May 31). An assistant in the Laboratory of Zoophysiology of the University of Copenhagen, mainly for research work in respiratory metabolism and gas analysis—Prof. A. Krogh, The University, Copenhagen. A teacher of design, with special reference to the textile industry, at the Leicester College of Arts and Crafts—The Registrar. A senior biology mistress at the Cheltenham Ladies' College—The Principal.

Our Astronomical Column.

THE BIELID METEOR SHOWERS.—Mr. Willard J. Fisher, of Harvard Observatory, contributes a paper to *Proc. Nat. Acad. Sciences*, Dec. 1926, in which he collects a large amount of material relating to various apparitions of these showers, and plots them in the endeavour to trace the laws of their recurrence. In 1741 and 1798 the shower occurred on Dec. 6 and 7; there were also December showers in 1830, 1838, and 1847, but all since then have been in November, owing to the motion of the node. On plotting the showers they appear to group themselves along four different lines, indicating presumably that there are several condensations of meteors along the orbit, their periods being slightly different. Many of the brighter showers are separated by intervals of 13·0 years (double the period of the comet). It is noteworthy that three of the four lines in the diagram converge towards a point a few years ahead of the present time, when the date of the shower will be Nov. 16. It will be well, therefore, to keep a careful watch for these meteors in coming years.

COMET GRIGG-SKJELLERUP.—It is curious how this comet has consistently been associated with the British Astronomical Association. It was found both in 1902 and 1922 by members of the Association, Mr. J. Grigg of Thames, New Zealand, and Mr. Skjellerup of Cape Town. The suggestion of identity was first made by Mr. R. T. Crawford and Mr. W. F. Meyer of California, but it was Mr. G. Merton, another member of the Association, who finally proved it, and made a prediction for the return of the present year.

Mr. F. J. Hargreaves, the director of the photographic section of the Association, was the first to photograph the comet at the present return, on two successive evenings, Mar. 27 and 28. It was Mr. Merton who detected the very faint images of the comet, Mr. Hargreaves having overlooked them. Further confirmation was obtained by a photograph taken by Prof. Schorr at Bergedorf on Mar. 31. Mr. Hargreaves uses an aero-lens of 20 inches focus, the mounting being home-made. It is a great encouragement for amateurs that this tiny equipment beat the instruments at the Yerkes and Harvard Observatories, which reported in the same week that they could obtain no trace of the comet. The explanation is that such large, faint, diffused objects are specially adapted to small-scale photographs using a large light-ratio. The deduced date of perihelion is May 10·245, 1927, U.T., which is only one-tenth of a day earlier than Mr. Merton's predicted date, May 10·34. This date had been communicated to Mr. F. E. Seagrave, who published ephemerides based upon it, but without mentioning Mr. Merton's name.

The corrected elements are as follows:

T 1927 May 10·245 U.T.

$$\left.\begin{array}{llll} \omega & 355^\circ & 1' & 48'' \\ \Omega & 215 & 32 & 1 \\ i & 17 & 29 & 18 \end{array}\right\} 1927\cdot0$$

ϕ 43 48 58

log q 9·95068

Period 4·98772 years.

Ephemeris for 0^h U.T.:

	R.A.	Decl.	[log r	log Δ.
Apr. 6.	5^h $58{\cdot}6^m$	1° 25′ S.	0·0123	9·7642
14.	6 11·8	1 17 N.	9·9896	9·7213
22.	6 27·3	4 43	9·9707	9·6676
26.	6 36·1	6 49 N.	9·9633	9·6363

The comet will approach within 19 million miles of the earth early in June. It will probably be a difficult object to observe accurately, being large and diffused.

Research Items.

THE DIVINITY OF THE GUEST.—In the *Ceylon Journal of Science*, vol. 1, Pt. 3, Mr. A. M. Hocart discusses the position of the guest and his relation to his host in ancient Greece, in India, and in Fiji. In ancient Greece no distinction was made between a stranger, a host, and a guest, as they were not distinguishable. Further, not only was the god present with the stranger, and Zeus the patron of strangers, but also he was often regarded either as a god or actually was a god, as is shown in the manner in which Odysseus was addressed in Phaeacia. The exchange of gifts and the return of hospitality, potential or actual, created a bond of hereditary guest friendship out of which grew the consular system in historical times. The idea that the god accompanied strangers was evidently a check on an unhospitable age. In India, in the Atharvaveda the divine character of the guest is worked out in detail, every act of hospitality being identified with some phase of the sacrifice to a god. In the Anguttara Nikaya, the offerings to the Manes include a reception of guests, who are selected either as being learned or virtuous Brahmans, or as being relations through females. In Fiji, various ceremonial observances towards strangers, including the making of gifts, point to their sacred or heavenly character. In Fiji, however, intercourse takes place only through kinsmen, the kinship being either actual or, in case of necessity, fictitious. It is reckoned through the female. There was also a system of official guest friends. It is suggested that the Homeric system may have developed from some such archaic form as the Fijian, India being the common link in which the offerings to kinsmen and guests are distinguished, while in Fiji the recipients are identical; but in both countries divine honours were accorded to guests. The resulting hypothesis is that the divinity of the guest grows out of the divinity of the kinsman, who stands in cross relationship to the host, and this is extended fictitiously to any stranger.

WEAPONS AND ARMOUR OF THE PHILIPPINE ISLANDS.—A description by Mr. Herbert W. Krieger of the collection of primitive weapons and armour of the Philippine Islands in the United States National Museum, which appears as No. 137 of the Museum's *Bulletin*, is of a wider ethnological scope than its title might suggest. The author, in his introductory remarks, deals not only with the history of the collection, which is derived from a variety of sources, and has been given at different times, but also with the development of the types of weapons of the Islands and of their tribal cultures. The various types preserved in metal, bone, wood, and horn, bear traces of the several waves of civilisation that have reached the Philippines. They extend from the primitive digging stick, which may be a club or, with slight adaptations, an axe, a spear, a sword, a knife, or a hoe, down to the cannon of brass and firearms of Spanish manufacture in the possession of insurrectionary native troops. Tribal groups and nationalities manifest in their weapon production and types of body armour and shields a nearness to, or remoteness from, foreign culture influences. No one group has retained exclusively any one type of material culture. Some elements survive from a primitive Melanesian strain; other tribes show borrowings from the aboriginal Negrito: the Batak use the blowgun, a typical Malay weapon, while the Negritos of Zambales and the Luzon east coast use the Malay shield. Fine iron and steel blades, which have come to be recognised as characteristic of the Mohammedanised Moros, show a decorative design on the blade and a blade form invariably of Hindu or Arab character. Although the Spaniards found a crude crucible of stone in use for crushing gold ore and quartz, there appears to have been no stone age in the Philippines. Bamboo furnished in early days all the material required for implements and weapons until those made of iron were introduced from Borneo.

CLASSIFICATION OF HEMIPTERA.—The greater part of Vol. 7 published by the Connecticut State Geological and Natural History Survey, 1923–1925, is occupied by an extensive memoir of more than 800 pages forming Bulletin 34 of the Survey and entitled "The Hemiptera or Sucking Insects of Connecticut." Its author, Dr. W. E. Britton, in collaboration with a number of specialists in different families of the order, has provided a trustworthy and authoritative guide to the classification of Hemiptera, which will be found useful to entomologists in many countries. The bulletin is virtually a text-book on its subject and is well illustrated and provided with a full index.

DISTRIBUTION OF FOOD FISHES IN THE NORTH SEA.—In *Fishery Investigations* (Min. Agric. Fish.) ser. 2, vol. 9, No. 4, 1926, Mr. J. O. Borley provides a series of most instructive charts portraying the quantitative distribution of the marketable sizes of the principal food fishes in the North Sea during the years 1923 and 1924. It should be noted that only fish taken by the trawl are treated; species such as the herring, which are very largely caught in other nets, are dealt with only in so far as they are trawled. The charts are drawn up from the landings of British steam-trawlers, referred to the place of capture. The areas to which landings are referred are small rectangles each 1° of longitude by 30′ of latitude; these vary somewhat in extent with latitude, from 1500 square miles in the southern bight of the North Sea to approximately 1200 square miles in the region of the Shetlands. Each chart depicts a set of contours which indicate the relative frequency of occurrence of one particular trade category of fish, in grades of abundance from less than 1 cwt. to more than 100 cwt. per 100 hours of fishing. A loose key-chart, printed on transparent paper and showing the approximate position and names of some of the chief fishing grounds, is provided, which may be superimposed on the others as desired. The whole work demonstrates very clearly the scientific value of the carefully compiled statistics of commercial landings at British ports. Some notes on the natural history of the fishes dealt with in the charts, prepared by Miss Thursby Pelham from a variety of sources, form a supplement to this publication.

FLEAS AND PLAGUE.—Vol. I., Pt. 4, of the *Ceylon Journal of Science* (Dec. 1926) is devoted to the results of researches by Dr L. Fabian Hirst on the parasitology of plague. He has returned to the important problem of the transmission of plague by the fleas *Xenopsylla cheopis* and *X. astia*. All attempts to transmit plague between rats, mice, and guinea-pigs by means of *X. astia*—596 fleas and a variety of methods were employed—at room temperature in Colombo during four plague seasons gave negative results. Plague was successfully transmitted to twelve rodents by means of 95 *X. cheopis* in the course of six separate experiments at room temperature Plague was successfully transmitted from mouse to rat at an artificially reduced temperature (70° F.) by means of *X. astia*; a female flea of this species with 'blocked' proventriculus transmitted plague to two out of four of the rats on which its bites were observed. Rise of temperature may exert an unequal effect on the transmitting power of two different species of rat-flea. The second part of the work deals with the bionomics of the two species of fleas—egg-laying, life-history, longevity (that of the female being greater), factors which influence biting, etc. A useful list of the rat fleas of the world is given, and appended is a brief account, with seven plates, by Stanley Hirst, of the principal species of Acari parasitic on rats.

POLLINATION EXPERIMENTS WITH PEAS.—More detailed observation of Mendelian ratios is revealing consistent departures from expectation, which have to be explained by differences in the conditions under which the pollen tubes grow down the style of a flower or in the viability and rate of growth of pollen tubes, as well as by reference to other features of flower structure. Dr. C. J. Bond (*Jour. of Genetics*, vol. 17, No. 3) has experimented on these points by pollination of the F_1 hybrids between pea varieties having respectively round yellow and wrinkled green seeds. By pollinating immature stigmas, he finds an increase in the recessives resulting, presumably because the pollen grains bearing the recessive factors, and probably containing more sugar, are more viable or grow faster when the stigma is finally ripe. He also finds a small increase in the proportion of recessives when minimal pollination, *i.e.* only a few pollen grains on the stigma, is used. The explanation of this probably lies in the ovules, as the effect is more marked when the seed-parent carries the recessive characters. Dr. Bond thinks he also gets evidence that the functional ovules in flowers on different parts of the plant bear somewhat different proportions of the dominant and recessive factors. Such results are to be expected with a more detailed knowledge of the physiology of the ovule and pollen development in the plant.

SPONTANEOUS COMBUSTION OF HAYSTACKS.—The losses to agriculture due to the spontaneous combustion of haystacks prove to be considerable. In *Matériaux pour l'étude des calamités* for July-September 1926, Mr. G. Laupper goes into the problem at length and shows from statistics drawn from Switzerland and Germany that such fires are commonest after a good hay season and are least frequent in poor hay years. The monthly incidence also shows a clear maximum in July and August, with high figures for October and November. The summer maximum he associates naturally with the initial high temperature of the hay after its thorough exposure to solar rays before and after being made into ricks, while a good hay season means that the hay is rich in hydrocarbons, the decomposition of which is at the root of the trouble. The yearly loss to agriculture through stack fires in Germany is calculated to be about one million pounds and in Switzerland to be little less. No sure means of prevention have been discovered. Layers of straw or salt in the ricks have been proved valueless, and ventilation is not a certain cure. The only measure that can be recommended is spreading the hay as soon as abnormal temperature is noticed.

THE SURVEY OF INDIA.—The General and Map Publication Reports of the Survey of India for 1925–26 have been published. The total area of new surveys of all kinds completed during the year was 42,489 square miles. About 45 per cent. of the total area assigned to the department has now been surveyed. Work for the new geodetic level net of India made steady progress. Tidal observations were continued as in past years. Map publication included five new sheets of the one-million map of India and adjacent countries, which is now nearing completion except for Arabia; twenty-seven new 'degree' sheets, sixty-nine half-inch and 127 one-inch sheets. The modern topographical map of India thus grows steadily, though only a little more than one-third of the total number of sheets have yet been published. The reports contain full index maps to the sheets available.

SIZE AND FIGURE OF THE EARTH.—Newton's theory of gravitation was held up for several years on account of lack of accurate knowledge of the size of the earth, and Newton himself first estimated the earth's figure from its speed of rotation. The determination of the size and figure of the earth has during the last two centuries exacted enormous labour from geodesists. It is generally assumed that the earth is approximately an ellipsoid of revolution, so that only the equatorial radius and the flattening have to be determined. Observations made in different regions of the globe are, however, rather discordant, the differences amounting to several parts in 100,000 as to the size and about 1 per cent. in the flattening. The labour which the observations have involved is so great that every effort should be made to make the fullest use of them. One difficulty in utilising the separate arcs which have been measured results from the fact that they have been discussed with respect to different figures. The figure of Clarke (1880) suits the European observations well, but a considerably different figure was deduced by Hayford from American observations, and this latter was adopted at the Madrid meeting of the Union of Geodesy and Geophysics as the reference figure for future calculations. To simplify comparisons, particularly with Clarke's spheroid, accurate tables have been computed for the Royal Geographical Society, and by means of these Mr. A. R. Hinks has discussed the principal geodetic surveys. He shows the impossibility of separating the two unknowns from arcs near the equator, and shows that different arcs fit different spheroids, and that those in India and South Africa do not fit any spheroid well. The difference in the results cannot arise from errors in the geodetic observations, but the astronomical observations may be effected to a considerable extent by local attraction, as in India. The probability is, however, that the approximation of the earth to a spheroid is only rough. Mr. Hinks points out that gravity observations can also be treated by a graphical process, and that they likewise indicate departure from a common spheroid when different regions of the earth are considered.

HELIUM CONTENT OF JAPANESE MINERALS.—On heating certain minerals containing helium, approximately 50 per cent. is evolved, and the method has been used by J. Sasaki to determine the helium contents of some Japanese minerals. The gases obtained by heating the powdered substances in an evacuated quartz-glass tube are passed over solid potash, red-hot copper oxide, and soda-lime to remove carbon dioxide and hydrogen. By sparking with oxygen in a eudiometer, nitrogen is converted into nitric oxide, which is absorbed by moist potash floating on the surface of the mercury, and the excess of oxygen is allowed to combine with melted phosphorus. The remaining impurities are removed when the residual gas is subjected to a discharge in a modified Geissler tube with liquid electrodes of a sodium-potassium alloy, and to the action of charcoal cooled in liquid air. Estimates of the geological ages of two of the minerals have been calculated by

Rutherford's method and appear together with the other data in the December issue of the *Bulletin of the Chemical Society of Japan*. The figure for monazite is 90 million years, and that for fergusonite 150 million years.

MAGNETIC ELEMENTS IN THE UNITED STATES.—The United States Coast and Geodetic Survey has recently issued two small pamphlets (Nos. 353, 360, price 10 cents each), one detailing the results of magnetic observations by the Survey during 1925, the other giving a chart, for the whole of the United States, of magnetic declination and its secular change per year, for the epoch 1925. The Survey issues such isogonic charts and secular-change data every five years, suitable stations being reoccupied during the intervening periods, in order to obtain the data necessary to carry the charts forward. With the chart is a full explanation of its construction and use to surveyors, also instructions to enable a surveyor to determine the declination with the aid of a compass and observations of the sun or stars. Tables are given for use in connexion with such celestial observations, and also tables of secular change in declination for a large number of stations, at intervals from 1750 to 1925. The first pamphlet (No. 353) gives observations of declination, dip, and intensity at respectively 330, 123, and 121 stations, widely scattered throughout the States, and including also some in the Philippines, Greenland, and the Aleutian Islands.

INDOOR ELECTRICAL ILLUMINATION.—It was stated by Mr. J. W. T. Walsh, of the National Physical Laboratory, in a paper on illuminating engineering which he read to the Institution of Electrical Engineers on Mar. 3, that 90 per cent. of the people in Great Britain carry on their work after daylight hours by an inadequate illumination and an unsuitable system of lighting. To quadruple the illumination and distribute it properly would result in better health and higher efficiency. The sources of illumination used in the early days cast unpleasant shadows. To get over this defect the indirect system of lighting, in which all the light from the source was reflected upwards to the ceiling and was then diffused over the room, was devised. The result was an almost complete absence of shadow, which, although suitable for a few special purposes, such as drawing-office work, was found to be most inconvenient for other work, such as sewing, where the shadows cast by the individual threads are a help. As a consequence of this defect, the modern semi-indirect system of lighting has been evolved. In this system part of the light is transmitted downwards through a bowl of diffusing material, while the remainder is emitted upwards to the ceiling as in the indirect system. The author considers that each of the three systems has its own field of usefulness. He thinks that in a lecture theatre, the totally indirect system has a tendency to appear lifeless and gloomy even though the amount of the illumination is ample. Some direct sources of light ought therefore to be provided in addition. The reflexion of a bright source of light from a polished surface or from a glossy paint or enamel often causes an objectionable glare. Methods should always be devised to obviate this.

ELECTRICITY SUPPLY.—In the *Journal of the Institution of Electrical Engineers* for March, Mr. J. R. Beard gives a report of the progress made in the transmission and distribution of electricity during the past year. He mentions that for many years the installation of transformer substations out-of-doors has been common abroad, and now, owing to the high cost of buildings, it is becoming common in Great Britain. Until recently all substations for converting from alternating to direct current were manually operated. Owing mainly to the increase in the rates of wages, automatic apparatus for starting up, shutting down, and controlling the apparatus in these stations is now largely used. Experience has shown that automatic control gives greater security than manual control. A recent development is 'supervisory control,' in which the operation of a number of automatic substations can be regulated from a central control point. This combines the accuracy of automatic control with the intelligence of manual control. All the substations on the 170-mile 3000-volt main line electric railway in Natal are operated automatically. Mr. Beard mentions one curious fact in connexion with low-voltage supply in Great Britain and the United States, namely, that while a pressure of about 230 volts is general in the former, a voltage of 115 is used in the latter. The reason seems to be that in the early days the life of the low-voltage lamps was much longer and their efficiency was much higher than that of high-voltage lamps. It is almost the universal custom in America for the supply authorities to supervise and maintain consumers' lamps. In Great Britain this is left to the consumer. Twenty years ago the low-voltage lamps were much cheaper to maintain, and so the over-all efficiency with their use was greater than that with high-voltage lamps. This, combined with the cheaper wiring systems used, explains why 115 volts is still the standard pressure in the United States. Mr. Beard sums up in favour of alternating current distributed in the three-phase four-wire system.

DOPES AND DETONATIONS.—A second communication from the Air Ministry Laboratory by Prof. H. L. Callendar and collaborators, dealing with the effect of antiknock compounds on engine 'knock,' appeared in February issues of *Engineering* (pp. 147, 182, 209). The previous report (Reports and Memoranda, No. 1013) led to the conclusions that detonation was due to the presence of nuclear drops in the charge in the cylinder during explosion, and that 'antiknock' concentrated in the drops, decomposed and protected them from oxidation by the formation of a metallic film or, in the case of the organic dopes, by dilution with a substance of high critical temperature. Such an explanation being inadequate to explain the different behaviour of various dopes, the present communication extends the work on the chemical side. It is found that detonation in paraffin fuels and ether is due to the accumulation of peroxide in the nuclear drops during rapid compression. The amount of peroxide formed would not in itself be sufficient to cause the detonation observed, but acts as a primer causing simultaneous ignition of the drops. The metallic dopes are considered to act by reducing the peroxides as fast as they are formed, preventing their accumulation, and thus delaying the ignition of the drops. The processes of slow combustion of various fuels are investigated by observing the temperature at which combustion becomes appreciable, the dopes being shown in this way to delay oxidation by preventing peroxidation of the fuel. A striking experiment is described, showing the difference in the kind of ignition obtained when the vapour of paraffin is ignited in a hot tube as compared with paraffin spray. In the former case the vapour burns with a quiet flame; in the latter the mixture burns with slight explosions and flashes of flame. The present communication adds to our knowledge of the behaviour of combustible mixtures.

Light and Growth.

THE action of light on plants has had a perennial interest for plant physiologists, and recently the subject has received some concentrated attention. Ferdinand Hercik (*Publications de la Faculté des Sciences de l'Université Masaryk*, No. 74, 1926) has tried to correlate the action of light and the surface tension of the expressed sap of his plants. He finds that the sap of normally grown seedlings of Lupinus, Sinapis, and Pisum has a greater surface tension than sap from stems of etiolated seedlings. On the other hand, sap from leaves of normally grown seedlings has a smaller surface tension than sap from leaves of etiolated seedlings. Now etiolated plants have usually greater stem growth and less leaf growth than normal plants, and the author correlates the greater surface tension with less growth and the smaller surface tension with greater growth. If, however, seedlings have the same length, then the surface tension of their respective saps is the same irrespective of the conditions under which they have been grown. The author has not traced the causal chain between the surface tension of the sap and the actual phenomena of growth.

In a series of papers in the *New Phytologist* (vol. 24, 5, and vol. 25, 3 and 4), Prof. J. H. Priestley deals with the problem from a slightly different viewpoint and advances some tentative explanations of his results. In the case of the broad bean (*Vicia Faba*) he was able to destroy some of the more marked etiolation phenomena by only very brief exposures to light—two minutes in every twenty-four hours. He points out that any change produced on etiolated plants by the action of light must be initiated, not by the effects of photosynthetic products, but by the photocatalytic effect of light upon the products of metabolism. For example, cells from the cortical region of an etiolated broad bean tip are incapable of being plasmolysed in a 17 per cent. cane-sugar solution, but, after exposure to artificial light for one hour on two successive days, are plasmolysed readily. The author considers that the photochemical action of light releases protein and fatty substances from the developing walls of the cells intervening between the central cylinder and meristem; and these walls, now consisting of purer cellulose, readily permit of the transfer of the nutrient sap from the central cylinder, with an ensuing more diffuse and more superficial development of merismatic tissue. In this way growth, which in the etiolated plant is confined to tips of stems, becomes redistributed.

The phototropic curvature of grass and cereal coleoptiles, the subject of much experimentation, is explained by Prof. Priestley on the basis of the foregoing hypothesis. Thus the side of the coleoptile exposed to the light becomes in consequence more permeable, with greater guttation through the apical hydathode from the vein nearer the light. The cells of the lighted side will therefore extend in length less than those of the darkened side, producing a curvature towards the light.

Following still another line of attack, Prof. Y. Yoshi has experimented on the influence of the relative length of day and night on plants (*Science Reports of the Tôhoku Imperial University*, 4th series, vol. 2, 2). His results, in the main, confirm and extend the work of Garner and Allard in grouping plants into two categories, long and short day plants, according to the length of daily illumination necessary for the production of flowers (*Jour. Agri. Res.*, 18, p. 553, and 23, p. 871). The evidence adduced leads to the conclusion that there is probably another group of plants which are nearly or entirely indifferent to photoperiods, but affected by other factors as to time of flowering. The author finds that the optimum photoperiod for reproduction does not result in maximum vegetative growth, and that closely related plants, sometimes even varieties of the same plant, may behave quite differently as regards photoperiods; for example, the late variety of rice plant is a short day plant, while the early variety is indifferent to regulation of light period. This seems to suggest that some other factors besides those concerned in photosynthesis are involved. If the photoperiod is the key to the distinction between spring and winter varieties of wheat, then researches along this particular line may have some application in the practical field of crop production.

Yorkshire Ammonites.[1]

THE amateur geologist who collects Yorkshire ammonites may approach the collection of papers before us with expectation, but he is likely to be disappointed if he hopes to identify his specimens from the descriptions there given. The work is not for the amateur, but for the specialist; and even he will have to dig deep in involved sentences to find the information which only so patient and expert a worker as Dr. Spath can give. These little papers have really an immense scope, gathering up and pronouncing upon outstanding uncertainties in the systematics of the main groups to which belong all ammonites commonly found in the Lower Lias; supplying new generic names where needed; and tilting at the evolutionary conceptions of previous ammonite workers.

To promote the first aim, Dr. Spath appeals to Yorkshire geologists to go into the field and collect Yorkshire ammonites bed by bed. In proposing new generic names, he considers that the quotation of a genotype is sufficient diagnosis. That would be more justifiable if the genotype were a species known by an existing holotype, and not mainly or merely by a figure. It is also probable that ammonite specialists the world over will miss the new genera thus casually proposed in notes on a local fauna in a journal which caters for amateur naturalists rather than professional palæontologists.

The fact is that Dr. Spath has tried to pack into these modest papers matter far beyond their scope, and he has condensed it almost to the limits of intelligibility. We feel that he could expand his remarks on evolution into an enthralling thesis, but here we can catch only the barest outline of his scheme. He has nothing but scorn for those who find comfort in supposed ammonite lineages, but he does not give them instead a clear-cut theory of evolution. The following points, however, seem to stand out: (1) The two great families, namely, Phylloceratidæ and Liparoceratidæ, persisted almost unchanged throughout the Mesozoic, and were the radical stocks whence group after group repeatedly sprang, rapidly evolved in many directions, and quickly died out. (2) Already in Triassic time all possible forms of ornament and whorl-shape had been tried, only to reappear again and again in later stocks (we must not say lineages). This seems to support a doctrine of Trends. (3) Even within a single species the young show very great variability, and on reaching maturity converge to a common form, thus refuting, in Dr. Spath's opinion, the doctrine of post-embryonic recapitulation. (4) New characters often appear first in the young, again proving that the doctrine of post-embryonic recapitulation is unsound. All these evolutionary pronouncements are of great interest, and would bear critical consideration, but here they can only be noticed, not discussed.

---

[1] Hull Museum Publications, No. 143 "Notes on Yorkshire Ammonites." By Dr. L. F. Spath Reprinted from the *Naturalist* for April-July, Sept.-Dec., 1925; Feb., May, June, Sept., Nov., 1926.

University and Educational Intelligence.

Bristol.—The following appointments have been made: In the Department of Chemistry, Dr. W. E. Garner, University College, London, to be professor of physical chemistry in succession to Prof. J. W. McBain, and Dr. Morris W. Travers, to be reader in applied physical chemistry and an honorary professor of the University. In the Department of Physics, Dr. J. E. Lennard-Jones, reader in mathematical physics, to be professor of theoretical physics; Dr. H. W. B. Skinner to a Henry Herbert Wills research fellowship in physics. Dr. L. C. Jackson was also appointed to a Henry Herbert Wills research fellowship some time ago.

It is hoped that the building of the Henry Herbert Wills Physics Laboratory will be completed in the summer, and that it will be ready for use by the beginning of next session.

Cambridge.—Field-Marshal Sir William Birdwood has been elected to an honorary fellowship at Peterhouse, a College with which he is closely connected by family ties.

R. O. Redman, St. John's College, has been elected to the Sheepshanks Exhibition in astronomy at Trinity College. The subject for the Adams Prize for the period 1927-28 is announced as "The Variations in the Earth's Magnetic Field in Relation to Electric Phenomena in the Upper Atmosphere and on the Earth." A theoretical contribution to the origin of the various phenomena and their qualitative and quantitative relations with each other is asked for.

London.—The following Doctorates have been conferred: D.Sc. in statistics on Mr. E. C. Rhodes (University College) for a thesis entitled (1) "On a Skew Correlation Surface," (2) "The Precision of Means and Standard Deviations when the Individual Errors are correlated," (3) "The Comparison of Two Sets of Observations"; D.Sc. (Engineering) on Mr. W. H. J. Vernon (Imperial College—Royal School of Mines) for a thesis entitled "The Atmospheric Corrosion of Metals (Second Experimental Report to the Atmospheric Corrosion Research Committee)."

Manchester.—Dr. Alex. M. Smith has been appointed lecturer in agricultural chemistry and adviser under the Ministry of Agriculture advisory scheme.

The Ella Sachs Plotz Foundation has issued its third annual report, from which it appears that thirty-eight applications for assistance in 1926 were received. Thirteen grants were made, seven of them to scientific workers outside the United States. For the present, research on problems in medicine and surgery is favoured, and preference is given to a group of investigations on a single subject; for example, four grants have been given each year for work bearing on the subject of chronic nephritis. Applications for grants for 1927–28 should be sent to Dr. Francis W. Peabody, Boston City Hospital, Boston, Massachusetts, before May 15.

Calendar of Discovery and Invention.

April 10, 1864.—The modern process of manufacturing open hearth steel was started by Pierre-Emile Martin, who melted together pig-iron, scrap, and iron ore in a Siemen's regenerative furnace. Martin's French patent was taken out on April 10, 1864. Two hundred years ago, Réaumur described the conversion of wrought iron into steel by fusing it with pig-iron, but his experiments never went beyond the laboratory stage. The open hearth process was introduced into America in 1868. In 1880 that country produced 1,074,000 tons of Bessemer steel, and 110,000 tons of open hearth steel. Forty years later these figures had increased to 8,883,000 tons of Bessemer steel, and 32,672,000 tons of open hearth steel, the total production being nearly equal to half a ton of steel per head of population.

April 11, 1709.—The most famous of all prizes for scientific work is the Copley Medal of the Royal Society. It was founded by Sir Godfrey Copley, Bart., who by his will dated Oct. 14, 1704, and proved April 11, 1709, bequeathed to Sir Hans Sloane and Abraham Hill "one hundred pounds in trust for the Royal Society of London for improving natural knowledge, to be laid out in experiments or otherwise for the benefit thereof as they shall direct and appoint." No award was made until 1731, when Stephen Gray, an inmate of the Charterhouse, received a prize for his electrical experiments. On Nov. 10, 1736, the Royal Society resolved to convert the bequest into a gold medal, Desaguliers receiving the first, and since then the medal has generally been awarded annually. Copley was a member of Parliament and held various public offices. In 1881 the then representative of the family, Sir Joseph Copley, transferred to the Royal Society a sum in Consols sufficient to provide in perpetuity an annual bonus of £50 to be given to the recipient of the medal (v. also Nature, Dec. 4, 1926, p. 823).

April 13, 1869.—The successful braking of trains was first solved by Westinghouse. A head-on collision between two trains directed his attention to the matter, and the chance reading of an account of the use of compressed air in boring the Mont Cenis Tunnel led to his experiments with an air brake. His first steam-air brake was patented on April 13, 1869. In 1872 he described the automatic brake, and the following year brought out his ingenious triple valve. In the famous trials on trains carried out by Sir Douglas Galton in 1878–9, the brake of Westinghouse proved its superiority, but it was afterwards much improved, Westinghouse alone taking out altogether 103 patents in connexion with it.

April 15, 1777.—A hundred and fifty years ago, in a letter dated April 15, 1777, Volta suggested to Prof. Barletti of Pavia the possibility of firing a pistol at Milan by the discharge of Leyden jars at Como, the two places being joined by an iron wire.

April 15, 1845.—Liebig is regarded as the virtual founder of agricultural chemistry. His famous work, "Die organische Chemie . . ." appeared in 1840, and it was on a barren plot of land outside Giessen that he made his experiments. His researches also led to the foundation of the artificial manure industry, and he himself, through James Muspratt, on April 15, 1845, took out an English patent, the object of his invention being "to restore to the land by means of a manure the mineral elements taken away by the crop which had been grown on and removed from the land."

April 15, 1893.—The finest pre-turbine British liner was the s.s. *Campania*, which on trial on April 15, 1893, developed 31,050 h.p. and attained a speed of 23·18 knots, her displacement being 18,000 tons. E. C. S.

Societies and Academies.

LONDON.

Royal Society, Mar. 31.—**Sir Robert Hadfield**: Alloys of iron and manganese of low carbon content. The range of alloys covers 0·06 per cent. to 38·90 per cent. manganese, also one additional alloy containing 83·50 per cent. manganese. With 4·00 per cent. to 10·00 per cent. manganese the alloys have a comparatively high Brinell hardness, in the region of 400, and are brittle; from 15·00 per cent. to 39·00 per cent. manganese, characteristics are observed similar to those of manganese steel, though only to a limited extent—that is, a comparatively low Brinell hardness, in the neighbourhood of 200, with considerable tenacity and ductility and fair capacity for work-hardening. The alloy containing 83·50 per cent. manganese is hard, brittle, and unforgeable. With 16·00 per cent. or more of manganese the alloys are non-magnetic, whereas in the presence of 1 per cent. of carbon not more than about 7 per cent. manganese is required to take away or suppress the magnetic qualities of the iron. The electrical resistance, while increasing with manganese percentage up to 87·2 microhms per cubic centimetre for the 38·90 per cent. alloy, does so in a fairly continuous manner and without any changes of a critical character such as those observed for the specific magnetism. In their corrodibility the alloys show under some conditions a somewhat improved resistance as compared with ordinary steel, but not such as to make them of any practical value in this connexion. In their micro-structure the alloys with increasing manganese percentage pass at 4 per cent. from a pearlitic structure to a martensitic, which at about 16 per cent., that is, the point where almost completely non-magnetic qualities appear, changes into the austenitic type.

E. Griffiths: The thermal and electrical conductivity of a single crystal of aluminium. A method is described for the determination of the thermal conductivity which does not necessitate any machining of the crystal. Tests were made at various temperatures, the value of the thermal conductivity at 100° C. being 0·55 C.G.S. units. The specific electrical resistivity is $2·89 \times 10^{-6}$ ohms per centimetre cube at 18° C.

W. L. Webster: The transverse magneto-resistance effect in single crystals of iron. The change of resistance of single crystals of iron produced by a transverse magnetic field has been investigated. Measurements were made with the current along a {100}, {110} or {111} crystal axis, and with the field in a series of positions in the plane normal to these directions. The phenomenon is of a double-nature. There is in all cases a gradual decrease in resistance approximately proportional to the field, and probably due to the action of the field on the conducting electrons. Superimposed on this effect there is a sudden change in resistance between 5000 gauss and 12,000 gauss, the sign depending on the direction of the current and the magnitude on the direction of the field. This second effect is probably caused by the change of orientation of the atoms accompanying magnetisation.

W. A. Bone, R. P. Fraser, and F. Witt: The initial stages of gaseous explosions. Part iii. The behaviour of an equimolecular methane-oxygen mixture when fired with sparks of varying intensities. Sparks of varying intensities were passed between electrodes fixed half-way along a horizontal glass tube (35-50 cm. long by 2-2·5 cm. diameter), both ends of which were *closed* in one series of experiments but *open* in another. The new evidence, which mainly lies in the photographs taken, shows (*a*) the occurrence, under ordinary sparking conditions, of what seems to be a definite 'induction period' as a preliminary to the actual combustion; (*b*) initial propagation through the medium of a 'ghost-like flame' condition involving only a very partial combination of the gases; and (*c*) the main combustion, following later as the result of the superposing of a compression wave, or the like, upon a system which during the phase (*b*) has already become highly sensitive to chemical changes.

F. T. Meehan: The expansion of charcoal on sorption of carbon dioxide. Wood charcoal expands when it sorbs carbon dioxide, and the process is reversible. The relations between expansion, pressure and temperature are similar to those connecting quantity of gas sorbed with pressure and temperature. Thus at constant temperature the expansion is related logarithmically to the gas pressure; at constant pressure the expansion is inversely proportional to the temperature. The same relations hold above and below the critical temperature of carbon dioxide. As the expansion is uniform in the three original grain directions, it appears that carbonisation destroys the structure of wood, leaving an isotropic product.

J. E. Lennard-Jones and **W. R. Cook**: The equation of state of a gaseous mixture. A theoretical formula is given for the equation of state of a gaseous mixture, and from it is deduced a generalisation of Dalton's partial pressure law. The forces between the unlike molecules of a mixture can be deduced.

Aristotelian Society, Feb. 21.—**A. Wolf**: Some aspects of the philosophy of Spinoza. The paper dealt with some common misinterpretations of Spinozism. The chief of these are (1) the quasi-Kantian interpretation of the Attributes as subjective ways of regarding Nature, instead of as objective characters of Nature; (2) the mistranslation of *infinite* attributes by *innumerable* attributes, instead of simply "all the Attributes," which may not exceed the two known to man, namely, extension and thought; and (3) the logico-mathematical, instead of the dynamic, interpretation of the attributes in relation to finite objects. The last was specially emphasised, as it obscures the relation of Spinoza to the science of his time and of ours. Reality for Spinoza was essentially activity, energy. Spinoza criticised Descartes' conception of matter as mere extension, saying that from such inert matter the world of physical phenomena could not be derived. For Spinoza matter was essentially energy occupying space. The inert idea of matter had eventually to be abandoned, and, in spite of Newton's protest, matter came to be regarded as kinetic of its own nature, so as not to need an external mover. Similarly with Spinoza's conception of thought; ideas, he insisted, are not dumb pictures on a tablet, but active assertions. While European psychology was for many generations obsessed with the conception of mind as a passive tablet on which sense stimuli make impressions, Spinoza already anticipated present-day dynamic conceptions in psychology, as he anticipated the general kinetic conceptions of physics.

Geological Society, Feb. 23.—**W. D. Lang** and **S. Smith**: A critical revision of the rugose corals described by W. Lonsdale in Murchison's "Silurian System." These forms include some of the earliest-described British Silurian forms. A detailed examination has been made of their external characters and the internal structure with the object of putting the nomenclature upon a sound footing.—**L. G. Anniss**: The geology of the Saltern Cove area (Torbay). The series here termed Red Shale Group (Upper Frasnian and Lower Fammenian) are overthrust on the north by the Staddon Grits and Shales (Upper Coblentzian), and on the south by the 'Massive Limestone' (probably Lower Frasnian). The 'Massive Limestone' forms the high ground on the south and also the summit of Sugar Loaf Hill, between which denudation has cut a deep valley exposing the Upper Devonian as a 'window.' The latter is a series of Red Shales, thin limestones, and tuffs. From these beds goniatites have been collected, which fix the fossiliferous horizon on Zone Iγ of Wedekind. Associated with the Upper Devonian is a decomposed albitedolerite; this rock has no connexion with the intrusions of the Torquay and Dartmouth areas, but is comparable with those of the Ashprington and Totnes areas.

Association of Economic Biologists, Feb. 25.—**F. Tattersfield** and **C. T. Gimingham**: During laboratory and field experiments on contact insecticides, an apparatus and technique have been devised for the quantitative study of the toxicity of contact insecticides, both to adult insects and to insect eggs, and some relationships between chemical constitution and toxicity in certain groups of synthetic organic compounds have been worked out. The results of the laboratory work have led to experiments in the field with certain compounds, highly toxic to insect eggs, which may prove to have practical value for winter spraying. The toxic properties of extracts of some tropical plants have also been studied.

Society of Public Analysts, Mar. 2.—**E. Richards Bolton** (Presidential address). The new preservatives regulations were welcomed. The adulteration of food is steadily decreasing, partly owing to the activity of the authorities, and partly to the efficiency of public analysts. Manufacturers should avail themselves of the services of a chemist to maintain the purity of their products and advise them in order to enable them to avoid any contravention of the law. The food of Great Britain was never in a purer state than it is at the present time.—**A. W. Knapp, J. E. Moss**, and **A. Melley**: Cacao butter substitutes and their detection. The most useful single test is the determination of the 'titre' of the fatty acids, and in the absence of certain other fats (*e.g.* coconut oil) this test enables the amount of Borneo tallow in admixture with cacao butter to be approximately determined after reference to a curve. A new method of determination has been based on the fact that the green colour of Borneo tallow is not bleached by ultra-violet light, whereas the yellow colour of cacao butter is readily bleached.—**H. W. Bywaters, F. T. Maggs**, and **C. J. Pool**: The determination of illipé butter in chocolate. Melted illipé butter becomes turbid at a much higher temperature than cacao butter, and the turbidity temperature determined under definite conditions is practically constant for different specimens of the two fats. If a third fat (*e.g.* milk fat) is also present, the percentage of illipé butter may still be found by reference to a curve, provided that the amount of the third fat can be ascertained.—**A. F. Lerrigo** and **A. L. Williams**: A study of the determination of saccharin, colorimetrically and by the ammonia process (work done under the Analytical Investigation Scheme). None of five colour reactions of saccharin studied under variable conditions gives quantitative results. The ammonia process (in which saccharin is converted into the ammonium salt of sulphobenzoic acid, the ammonia in which is determined by distillation) has been adapted to the determination of small quantities of saccharin.

Linnean Society, Mar. 3.—**A. J. Wilmott**: The Irish Spiranthes called *S. Romanzoffiana* Cham. Specimens from County Cork and Lough Neagh are distinct; the southern one is *S. gemmipara* Lindl., and the northern one *S. stricta* Rydberg.—**J. Davidson**: On the occurrence of intermediates in *Amphis rumicis* L. and their relation to the alate and apterous viviparous females. In *Aphis rumicis* L. (Hemiptera, fam. Aphididæ) both alate and apterous viviparous females (virginoparæ) develop in the parthenogenetic generations. The alate forms tend to produce apterous forms, and the apterous virginoparæ produce only apterous forms or a mixed progeny of apterous and a variable percentage of alate forms. From time to time intermediate individuals develop. Compared with their immediate alate and apterous relations in the same generation, these intermediate forms behaved as apterous forms.

EDINBURGH.

Royal Physical Society, Feb. 21.—**Isobel Deans**: The genus Hicksonia: an account of a new species. A new species, *Hicksonia köllikai*, is described. Attention is directed to the occurrence of telestid-like spicules which suggest the derivation of telestids from clavularids.—**D. Chalmers**: Worm parasites of common marine fishes. The results of an examination of specimens of sixteen species of North Sea fishes. Thirty-one species of parasitic worms are described, including three new, or hitherto unrecorded in the present host.—**C. Cumming**: Re-investigation of the eye of the mole. Embryonic development and histological structure of the eye of the mole are described. The whole of the eye shows a simplification. The lens is degenerate, the retina partly so; normal image perception is impossible.

PARIS.

Academy of Sciences, Feb. 28.—**S. Winogradsky**: Researches on the degradation of cellulose in the soil. Hutchinson and Clayton, in 1919, isolated the first typical representative of the group of aerobic bacteria attacking cellulose, and the author has followed the same general method. A dozen forms have been isolated falling in two groups, Cytophaga, the type discovered by Hutchinson and Clayton, and vibrions. In the latter group, the fibrolytic action is much less marked than with the Cytophaga, but they spread over paper with great rapidity.—**A. Weinstein**: A problem at the limit in an indefinite band.—**Paul Lévy**: The iteration of the exponential function.—**G. Pólya**: The singularities of the lacunar series.—**D. V. Jonesco**: A class of functional equations.—**C. Cerf**: The integration of systems in involution of partial differential equations.—**Mandelbrojt**: A complement to the theorem of M. Fatou.—**G. Sugot**: The integration of the differential equations of the gyroscopic movement of a projectile.—**Kolossoff**: A transformation of the equations of elasticity.—**J. Vorobeitchik**: The horizontal flight of an aeroplane with great radius of action.—**J. Thovert**: The propagation of aerial waves in large subterranean cylindrical mains. The proved lack of uniformity of temperature in large underground mains will tend to give low values for the velocity of sound in such tubes. It would appear to be impossible to apply a suitable correction.—**Belin** and **Holweck**: Television. First results in the transmission of moving images.—**J. Cabannes** and **P. Daure**: The absolute measurement of the intensity of the light diffused by benzene in the liquid state. On the basis of measurements on the light diffused by benzene and other liquids, the authors conclude that it is not at present possible to deduce the Avogadro number from measurements of the diffusion of light by liquids.—**Pierre Jolibois, Henri Lefebvre**, and **Pierre Montagne**: The chemical yield in the decomposition of carbon dioxide under small pressure by the condensed spark. The experimental results cited agree with the theoretical conclusions deduced from the study of the thermal dissociation of carbon dioxide. The energy of the electrical discharge is only partially utilised in the form of chemical energy, and the figures expressing the yield are notably lower than those calculated on the supposition that the spark produces in the gas uniquely a heat development absorbed quantitatively by the gas.—**Albert Kirrmann**: A method of synthesis of α-bromoaldehydes. The general method proposed is the action of phosphorus chlorobromide, PCl_3Br_2 on the acetals $R.CH_2.CH(OR)_2$. This reaction gives the α-bromaldehyde $R.CHBr.CHO$ together with RBr, HBr, phosphorus trichloride and oxychloride. The method is practicable starting from C_4, and gives good yields above C_5. The physical properties of five bromoaldehydes prepared by this method are given.—**Paul Gaubert**: The formation in the insoluble state of two hydrates of magnesium platinocyanide.—**Ch. Gorceix**: The variation of longitudes can be attributed to another cause than the drift of the continents.—**C. E. Brazier**: The periodicity of the magnetic disturbances observed at Parc Saint-Maur and at Val-Joyeux. The results of a statistical analysis of 36 years' observations tend to show that the days on which there are magnetic disturbances succeed each other at intervals of which the approximate duration will be equal to one of the numbers obtained by multiplying the period of synodic rotation of the sunspots by a simple fractional factor, between 0·5 and 3.—**R. Combes**: The nitrogen in a ligneous plant in the course of a year's growth.—**Volmar** and **Samdahl**: The constitution of α-kirondrine. Owing to the small quantity available for study the constitution of α-kirondrine could not be completely determined. It is a bitter toxic principle which is neither an alkaloid nor a glucoside but a lactone containing one or more aldehyde groups.—**A. Demolon** and **G. Barbier**: Study of the mechanism of the exchanges of ions in the clay-lime complex.—**A. Rochon-Duvigneaud** and **M. L. Verrier**: The existence of serous pockets in the orbit and in the eye of the teleosteans.—**Béhague**, **Garsaux**, and **Charles Richet**, jun.: The rhythm and respiratory frequency of animals submitted to a barometric depression.—**Pierre Lesne**: The subfossil Gyrinus of Belle-Isle-en-Mer.—**Armand Dehorne**: The annual reproductive cycle of *Dodecaceria concharum* at Le Portel.—**Louis Bounoure**: The primary gonocytes in the embryos of toads from eggs submitted to uterine super-maturation.—**A. Fernbach**, **M. Schoen**, and **Motohichi Mori**: Some observations on the so-called elective fermentation. It has been held that the differences in the velocity of disappearance of various sugars in a mixture was due to differences in the resistance that the cell-wall of the living yeast offered to the passage of the various sugars. It is now shown that these differences do not depend on the presence of the living yeast, but are also shown by zymines prepared according to the technique of Albert, Buchner, and Rapp. The causes of this selection still remain obscure.—**A. Marxer**: The proteolytic ferment of *Bacillus subtilis*.—**Maurice Letulle** and **Louis Vinay**: Experimental cancer of the lung.

Vienna.

Academy of Sciences, Jan. 27.—**F. Holzl**: The alkylisation of ferrocyanic acid.—**R. Frisch**: The action of slow cathode rays on rock-salt.—**H. Küpper**: Elucidation of morphogenesis and tectonics at the edge of the Vienna basin.—**A. Smekal**: The coloration of rock-salt crystals by radium radiation.

The Development of Natural History Museums.

AT the present time there are scores of natural history museums, national, municipal, and semi-private, scattered throughout the British Isles, all attempting to serve science by presenting to the people the crude material of scientific study and, less generally, the results of certain kinds of scientific research. Their condition causes uneasiness to the onlooker who realises how potent an instrument museums might be in instilling scientific knowledge and creating that staunch popular backing which is necessary to bring science to its own in the life of the nation.

The story of many, perhaps the majority, of provincial museums is the same. They begin in a burst of enthusiasm, the white heat wanes, the care of the collection falls upon a dwindling number of voluntary workers, there is no proper provision for upkeep, and the end is disrepair, mouldy collections, dust-laden shelves—the 'museum' of the comic papers. These museums need encouragement, help, and money. The Carnegie United Kingdom Trustees have decided upon a work of national importance in undertaking, with the help of Sir Henry Miers, an inquiry into the conditions of these "imperfectly organised and to a large extent unappreciated" institutions. The national museums and the museums of the larger municipalities stand in a different category. They are for the most part well tended and well cared for, their exhibited collections are kept up-to-date, in so far as up-to-dateness is satisfied by the replacement of poor specimens, the occasional filling in of blanks and a little more. But have even these museums realised the need of marching with the advance in knowledge?

The purpose of a great natural history museum is twofold, as Sir Ray Lankester has pointed out in a recent letter to NATURE (Feb. 26, p. 314). It is a storehouse for the safeguarding of objects of natural history which are of historic interest, and of the vast collections of specimens gathered from every quarter of the globe and from the world's seas. On these are founded to a large extent our knowledge of the basic natural history of geographical regions, and they afford the raw material for further researches, geographical, morphological, and phylogenetic. Much more importantly, so far as the living generation is concerned, they give the ordered facts on which alone can be based the war against disease, and the search for Nature's wealth, which together determine the economic fate of the human race; but this is an aspect which demands description by specialists. For all these ends the storing of such material, if it is to be at all valuable for reference, demands a minuteness of classification in proportion to the extent of the collections, and therefore a prime duty of a museum staff must be that of the systematic classifier.

The other great purpose of the large museum (and almost the sole purpose of the small museum) is exhibitory and educative, for the instruction not only of the unlearned but inquiring public, but also of all grades of receptive mind even to the professional expert, since there is no book-knowledge but may be bettered by reference to the facts themselves, and these could often be displayed from the great stores of museum properties. The growing recognition that an essential duty of museums supported by the public purse is educative, is shown in the placing of the newer State museums under the departments identified with public education, the Victoria and Albert Museum under the Board of Education, the Royal Scottish Museum under the Scottish Education Department. It is a kind of linkage that might well be extended to other public museums, provided the State department concerned is prepared to recognise and develop the enormous teaching potentiality of museums instead of permitting them to adhere as excrescences on the educational body.

Have the natural history museums in Britain played up to their educational function? They have not. Take the Natural History Museum at South Kensington, not because it is worse than the others, but because its size emphasises the defects. Its galleries are for the great part filled with thousands of specimens arranged 'systematically.' The principle underlying systematic natural history is phylogeny, that is to say, systematic collections must be looked upon as illustrating natural relationships and ultimately the evolution of life upon the globe. Since no one can claim that these great collections with their multiplicity of genera and species *visibly demonstrate* throughout the series natural relationships or the lineage of animal life, their primary purpose fails, and they must be regarded mainly as groupings convenient for showing a conspectus of the animal world and for the identification of specimens.

How do the collections meet these needs? It is impossible as a matter of quantity to exhibit every species; it would be useless from a qualitative point of view to do so, for the discrimination of the modern expert seizes upon differences invisible even to the observant eye. But this impossibility makes accurate identification from the exhibited collections a hazardous matter for the non-expert. The collections meet neither the phylogenetic nor the identification point of view. The indication is that their future development must be along the lines of drastic reduction, so that the series shall contain only readily distinguishable forms selected because of their historical, phylogenetic, or morphological interest, or because of a special attractiveness in themselves.

The implication of such a reduction is important. It means that, more and more, not only the specialist but also the general inquirer after detailed knowledge must be encouraged to supplement his observations in the galleries by appeal to the cabinet collections. This demands the presence of facilities not at present available in the museum, of easily accessible store collections, of well-lit, well-equipped, reasonably comfortable rooms available for the outside inquirer. Much more it implies such facilities for the museum staff which spends a lifetime organising and sorting the collections in gallery and in cabinet. Hitherto, in this technical aspect of reference collections containing specimens authoritatively named, the British Museum has been the central museum of the world. This position depends largely on the proportion of original specimens, 'type-specimens,' deposited by the naturalists who have named them; and obviously, the museum which has already the widest collection is the museum in which a new type-specimen can be most usefully deposited. It is to examine these type-specimens that naturalists visit England from all over the world. The hidden cabinets form the 'British Museum' which is the premier natural history museum in the world; it remains to be seen whether it can retain this position in face of the intelligent expenditure of America and Germany.

Sir Ray Lankester suggests that the exhibition space saved (and he contemplates reduction by one-half) might be used for the purpose of bringing up-to-date this hidden British Museum of research. With this view we disagree. There is a better purpose for the exhibition space, for the Natural History Museum has scarcely touched the fringe of real education, which must become part of the duty of a State museum. The greater American museums have spent much ingenuity and vast sums of money on the creation of realistic Nature groups, which transport the spectator into new realms. The main hall of the Natural History Museum at South Kensington, with its dark alcoves, is admirably adapted for such groups, and might well be given over to this purpose. But while such groups are instructive, their main interest is spectacular, and the public demands more than a pageant: it thirsts for a deeper knowledge.

Nearly seventy years ago, Charles Darwin, an Englishman, with a new view-point revolutionised the thought of the world. What has the Natural History Museum of his own country done to make Darwin's world-moving discoveries current amongst his own people? What has it done to convert the 'fundamentalists,' of whom Great Britain as well as America has its share? Nothing! Except for a few isolated exhibits, shown almost in holes and corners as if with an apology lest they should intrude upon the systematic collections. Yet Darwin's mind was detailed and material; his theories are not as it were in the air; they rest upon accumulated facts and examples of a kind eminently suitable for exhibition in a museum. Some years ago the late Dr. Benjamin Peach in arranging the collections of Hugh Miller in the Royal Scottish Museum, Edinburgh, placed together a few of the actual specimens which had led the Cromarty stone-mason to certain of his conclusions. This practice might be extended. There is a vast body of general biological truths of vital importance in scientific thought, which could be illustrated, not by one or two examples, but by such a multiplicity of examples, culled from a wide range in the realms of zoology and botany, as would compel belief. Sir Ray Lankester thinks that such subjects—evolution, heredity, variation, natural selection, geographical distribution and variation, sex dimorphism, and hosts of others—should be the subject of museum lectures, and with this view we are in entire agreement; but how much more ought they to fill the galleries of a public museum for the constant reference and edification of the people?

Such collections to reach their highest efficiency must be planned and wrought out with a breadth of knowledge, and with a museum gift which is comparable to the creation of a striking and artistic poster; to them each specialist must make his contribution; they must be symposia rather than individual efforts. The hard-pressed specialists on the museum staff, overladen with identification and classification and the sorting of new collections, cannot spare the time and consideration demanded by such biological exhibits. The ideal exhibitor is by nature a creative artist; the British Museum authority, to consult whom a zoologist comes from Japan or a tropical pathologist from Uganda, should be by training a field-naturalist, must be by nature a methodist and a scholiast. The reorganisation of the exhibited collections on the lines of the advancement of modern natural history demands the reorganisation of the staff.

On this, as well as on the grounds summarised by Sir Ray Lankester, an inquiry by Royal Commission into the "status, purposes, and organisation of the British Museum (Natural History) and other related institutions" is urgently needed. There are many aspects of museum activities, relationships, and influences which might be bettered by inquiry and definition: the aims of the museum itself; the overlapping and duplication of collections in London; the relation of the State museum as an educator, to the recognised educational and particularly the teaching institutes; its relation to other natural history museums supported by State funds, and to the public museums of Great Britain in general; and not least, when the Dominions, Crown Colonies and dependencies are equipping staffs of researchers into the Nature which surrounds them and the death which encompasses them, who risk their lives to fight disease and to bear the torch of scientific knowledge to the ends of the earth, let the Government of our Empire consider the imperial relationships of the British Museum.

Ethnology of Tuareg Tribes.

People of the Veil: being an Account of the Habits, Organisation and History of the Wandering Tuareg Tribes which inhabit the Mountains of Air or Asben in the Central Sahara. By Francis Rennell Rodd. Pp. xvi + 504 + 51 plates. (London: Macmillan and Co., Ltd., 1926.) 30*s*. net.

By the "People of the Veil" are meant the Tuareg, whose country extends from the eastern edge of the central Sahara to the far edge of the western deserts of North Africa before the Atlantic zone begins, and from southern Algeria in the north to the Niger and the equatorial belt between the river and Lake Chad in the south. The name 'Tuareg' is not used by the people themselves; it is really a term of opprobrium originally applied to them by their enemies. They became known to the Arabs as the 'Veiled People,' because their men after reaching a certain age were, as they still are, in the habit of wearing a strip of thin cloth wound around their heads in such a manner as to form a hood over the eyes and a covering over the mouth and nostrils. only a narrow slit being left open for the eyes; and, in default of a national name, they themselves use the same locution in their own tongue to describe the whole society of different castes which compose their community. They are usually included among the Berbers of North Africa; but Mr. Francis Rennell Rodd, the author of the latest book dealing with them, prefers to use the geographical term Libyans, and even doubts whether the Tuareg are Berbers at all, like the other people so called in Algeria and Morocco. There are to-day four principal divisions of them. One of these groups consists of the people inhabiting Air, which is a mountainous oasis situated on a great caravan road from the Mediterranean to central Africa; and it is chiefly with this people and their country that Mr. Rodd's book deals in detail, as a result of a nine months' journey in the Tuareg country.

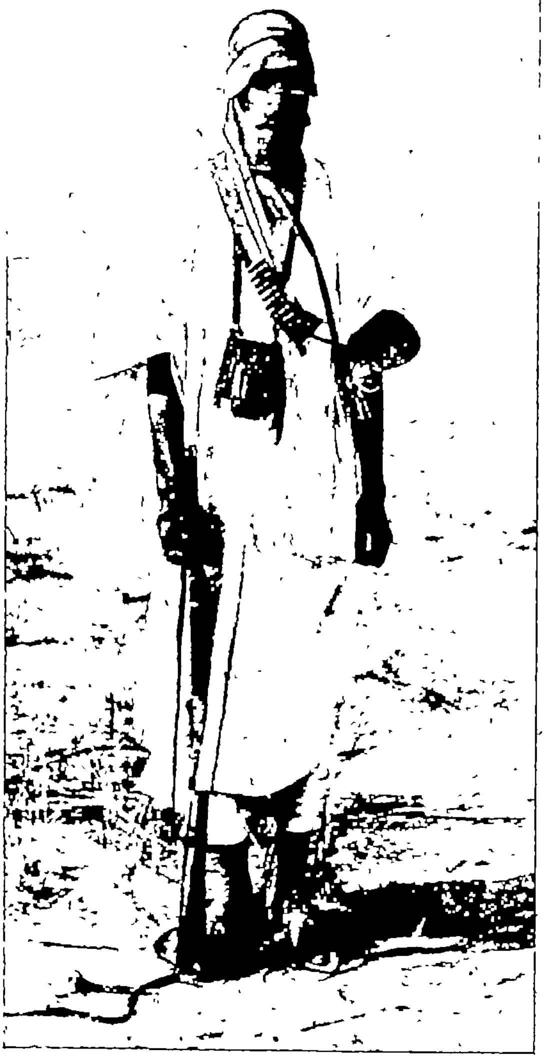

Fig. 1.—Tuareg camel-driver. From "People of the Veil."

The people of Air have for several centuries had a king, residing in the city of Agades, but he seems never to have enjoyed much authority, unless backed by the more important chiefs. His office is not hereditary, but he is elected by the representatives of certain tribes; and his tenure of office has always been very precarious. The reigning king is of slave descent, and the same has been the case with all his predecessors. The legal practice of slavery has of course been abolished in Air since the advent of the French in the beginning of the present century, but master and slave continue to regard each other by mutual consent in the light of their former relationship. Slavery among the Tuareg never involved great hardship; it was in slave-trading and not in slave-owning that they sinned against the ethical standards which are usually accepted in Europe. There are further the so-called *imghad*, or serfs, who are clearly the descendants of groups or individuals captured in war and afterwards released from bondage to form a caste enjoying a certain amount of freedom; they are in no sense considered to be the property of the noble tribe which originally possessed them, but the relationship is closer than that of suzerain and vassal. In the first stage the noble tribe represents the original pure Tuareg race, while the oldest *imghad* are the first extraneous people whom they conquered, "in some cases perhaps as early as in the Neolithic ages."

In addition to the social distinction between nobles and serfs, the Tuareg attach great importance to tribal classification. Among the inhabitants of the Air mountains a tribe is either of the category called the "People of the King" or of the Kel Owi, and this distinction means all that the difference between an ancient landed nobility and a parvenu commercial aristocracy denotes. Many of the older men of the "People of the King" say that there are no nobles among the Kel Owi at all.

In Air, as elsewhere among the Tuareg, a man's or woman's social status is determined by that of the mother; a woman, they say, carries her children before they are born, and so they belong to her and not to the father. If she marries a man of another tribe the children become members not of his but of her tribe; and Mr. Rodd states that "should inter-tribal hostilities break out they must leave their father and fight for their mother's tribe, even against their own parent if need so be." Similar statements have been made with reference to a few matrilineal peoples in other parts of the world, but they are quite exceptional and even of doubtful accuracy; hence it would have been well if the author had confirmed his assertion by actual cases in which Tuareg have been at war with their fathers on account of their method of tracing descent through the mother. He maintains that the frequency of monogamy is connected with the 'matriarchate.' But his statement relating to the Tuareg of Air, that in practice "monogamy is more frequent than polygamy," is true of all Muhammadan nations and of nearly all other peoples who allow polygamy, and nobody has ever been able to show that patrilineal peoples are more addicted to it than matrilineal ones; indeed, the prevalence of mother-right has, on the contrary, been partly traced to the practice of polygamy. Monogamy may certainly be a result of the regard in which women are held; but the supposition that their position in general is influenced by the system of reckoning kinship is not past all doubt.

Mr. Rodd observes that the Tuareg women are respected by their men in a manner which has no parallel in his experience, and that their unveiled countenances are in keeping with the perfect freedom they enjoy—though, wisely enough, he does not attribute the veil worn by the men to female supremacy. There can be little doubt that the veiling of women found in many parts of the Muhammadan world is not merely due to masculine jealousy but serves the object of protecting them from the evil eye, and in early Arabia very handsome men for the same reason veiled their faces, particularly at feasts and fairs; but though the belief in the evil eye is known to exist among the Tuareg, it does not seem to have anything to do with the veiling of their men. The author criticises some theories as to the origin of this peculiar custom, and is of opinion that up to the present no reasonable theory has been advanced. I think, however, that he has made a little too light of the suggestion that the veil was assumed by raiders who wanted to conceal their faces in order to escape recognition; he argues that the veil would be of little use as a means of concealment. I have heard Moors who have come in contact with Tuareg express a very different opinion, and among the mountaineers of northern Morocco robbers blacken their faces so as not to be found out. The veil is not worn until some years have elapsed after the youth begins to carry a sword.

While Mr. Rodd gives us much minute and valuable information about the organisation, the social conditions, the mode of life, the trade and occupations, the architecture and art, and the history of the Tuareg of Air, he has much less to tell of their rites and beliefs. Only a few lines are devoted to their customs connected with childbirth, marriage, and death, which may not be so uninteresting as he assumes; and he modestly says that he was not sufficiently fluent in their language to learn much of their superstitions. "Such information," he rightly remarks, "can only be obtained after prolonged residence among a people." He believes that the frequent use of the cross in Tuareg ornamentation is due to early Christian influence. It may be so; but the cross is much older than Christianity, and cruciform devices occur among the tattoo-marks seen on Libyans represented on old Egyptian monuments.

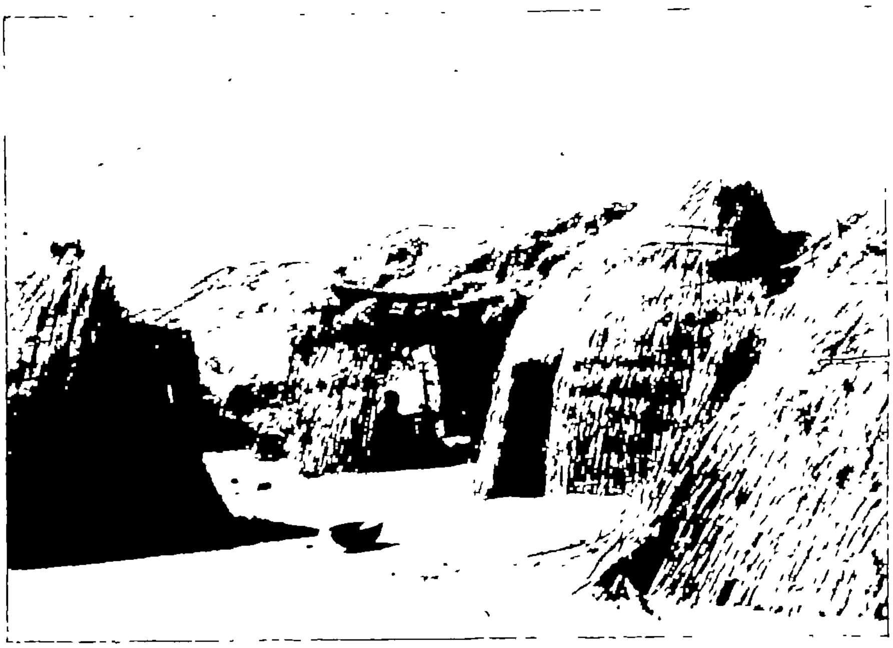

Fig. 1.—Tuareg huts at Auderas. From "People of the Veil."

It should be added that Mr. Rodd's book is an important contribution not only to our knowledge of the Tuareg, but also to the study of certain problems relating to the history and ethnology of the Sahara and North Africa in general. The illustrations are excellent. Edward Westermarck.

Q 1

Atomic Physics.

The Structure of the Atom. By Prof. E. N. da C. Andrade. Third edition, revised and enlarged. Pp. xviii + 750. (London: G. Bell and Sons, Ltd., 1927.) 30*s*. net.

PROF. ANDRADE'S well-known introduction to atomic physics has been very largely re-written for this (the third) edition, and the size of the work has been approximately doubled. Some of the discussions of the earlier editions have been amplified, but in the main the increase in size represents the introduction of new subject matter. As before, the book is divided into two parts, of which the first is nominally devoted to the nucleus. A great deal of extranuclear matter is, however, disposed of in this section, in order to clear the ground for the later discussion of the outlying portions of the atom.

After a brief historical introduction, pride of place is appropriately given to an admirable account of the passage of swift electrified particles through matter—the problem which primarily led to the enthronement of the nuclear theory of the atom. Rutherford's α-particle scattering is naturally dealt with in some detail, together with an outline of the rather less definite evidence obtained from β-particle scattering. There is also a (much too brief) reference to the fundamentally important observations of Ramsauer and others on the behaviour of inert gases towards slow cathode rays—observations now extended, with refined methods, to the more 'aggressive' gases.

Part I. is also distinguished by an excellent account of the remarkable work conducted by Rutherford and his school during the last eight years, on the effects of extremely close collisions between swift α-particles and the nuclei of light atoms—the 'artificial' disintegration of matter and the estimation of the 'size' of the nucleus. Other topics which are concisely but adequately presented are: positive rays (including Aston's work on isotopes), the evidence for 'energy levels' within the nucleus, the interpretation of β- and γ-ray spectra and the deduction therefrom of details of the process of radioactive disintegration. Separate chapters are devoted respectively to more speculative hypotheses on the structure of the nucleus, and to an excellent account of 'classical' X-ray work—including Moseley's establishment of the importance of the concept of atomic number, Barkla's application of the scattering formula to the determination of the number of extranuclear electrons, and W. L. Bragg's work on the average time-spatial distribution of these electrons. The necessary 'Digression' on optical spectra, which has been modified and enlarged, brings Part I. to a close.

Part II., which now occupies about three-fourths of the whole book, deals exclusively with the behaviour of the extranuclear electrons, and almost exclusively with the quantum explanations of this behaviour. A great deal of space is therefore allotted to the discussion of spectral series. This part of the discussion, which has been profoundly modified in the new edition, begins, inevitably, with the classical Bohr theory of the spectra of hydrogen and of ionised helium. This is followed by simplified expositions of Ehrenfest's adiabatic principle and Bohr's correspondence principle. The argument is then carried on to the case of 'hydrogen-like' atoms, in which two quantum conditions are required for the specification of the orbits, and to the problems of 'relativistic' fine structure, normal Zeeman- and first-order Stark effects. Examples are given of Sommerfeld's classical applications of the 'Sommerfeld–Wilson' quantising rules and of Bohr's use of the method of perturbations. After a preliminary attack on the spectrum of the general atom, with the evocation of selection rules and adoption of a third and fourth quantum number, the discussion of the spectroscopic evidence culminates in a remarkable chapter on multiplet theory and anomalous Zeeman effect. This chapter (xv.), which has been partially revised by Mr. R. H. Fowler, summarises some of the most eminent successes, and at the same time emphasises some of the most significant difficulties and inadequacies of the older quantum theory of line spectra.

Among other new chapters which enhance the value of the book, special reference must be made to an excellent summary of work on critical potentials. There is a particularly welcome account of Saha's theory—which is not always, even in astrophysical text-books, given the place it merits—and the extensions of Fowler and Milne. Klein and Rosseland's superelastic collisions, and resonance radiation (including quenching and 'sensitised fluorescence'), are briefly discussed.

The account of the evidence from X-ray spectra has been very considerably expanded, and now occupies a separate chapter. This chapter gives a useful account of measurements in 'soft' X-ray regions and of the transition from optical to X-ray spectra, and a brief discussion of the interesting dilemma of the 'relativity' doublets raised by the recent 'hot spark' work of Millikan and others.

The relation of the dynamical atom-model to the periodic system of the elements is much more fully discussed than in the earlier editions. An account is given of the Stoner–Main Smith modification of Bohr's original scheme, and McLennan's new table of basic spectral terms is added in an appendix (v.).

The chief addition to the chapter on magnetism is the extended account of the beautiful experiments of Gerlach and Stern, which is supplemented by a particularly fine reproduction of some of the original photographs. There is, however, no discussion of Glaser's work on diamagnetic gases at low pressures.

The relative positions of wave theory and classical quantum theory are summarised in a new chapter, which deals with dispersion, the Bohr–Kramers–Slater discussion of radiation fields, and the Compton effect.

The book closes with a brief but suggestive statement of the present position, and an account of the salient features of the newer quantum theory —or what seems doomed to be known for the present as the 'Born–Jordan–Heisenberg–Pauli–Dirac–Schrödinger . . .' mechanics.

The above—necessarily imperfect—analysis of the subject matter is intended to indicate the scope of the work, which is in many respects complementary to that of Sommerfeld's well-known treatise. It should be obvious that the book is primarily addressed to the traditional 'serious student' of physics. The treatment is, however, so ordered that much of the text is accessible to readers who have a general rather than a professional interest in modern speculations on the structure of matter.

The general plan has been to give a lucid account of the essential features of each problem, and to supplement this by a judicious selection of references to original sources. Space is economised here and there by omitting details for which English readers would naturally turn to such standard treatises as those of the Braggs, Aston, or Siegbahn. The result of this plan has been the production of a book which is specially adapted to serve as a general guide for senior students of physics and for those who are preparing to embark upon independent work. There are also, unfortunately, many older experimenters whose employment leaves them little time to keep in touch with new work which does not bear obviously and directly upon the subjects of their own special studies: to these, too, Andrade's book will make a special appeal.

The appeal in many cases will be none the weaker because the treatment is throughout physical rather than mathematical; and although the greater part of the book is necessarily allocated to the theoretical superstructure, unusual attention and respect are paid to the experimental methods and observational data at the foundations. The information has not always been brought completely up-to-date—it is many months since X-ray spectroscopy stopped short at such puny wave-lengths as 14 Å.U., and it is no longer held to be established that the absorption edges of an element depend upon the allotropic form, though it has been shown that the effect of valency can be exhibited even in the X-ray emission spectra of compounds—but oversights of this nature are inevitable in so comprehensive a survey. Certain omissions—as that of any discussion of band spectra—were also inevitable, as is pointed out in the author's preface; perhaps one of the most regrettable is the absence of any detailed discussion of the outstanding problem of X-ray absorption. As the problem by its nature is rebellious to direct treatment by the correspondence principle, which is the key to so great a part of the book, this omission is not unnatural.

Even if, as the author forecasts, much of the book will need to be rewritten in terms of the new mechanics and the spinning electron, the work in its present form stands as a very valuable exposition of the existing state of our knowledge of atomic structure, and one which is not likely to be superseded in the near future. The advances made even as the book was passing through the press are sufficient to demonstrate the futility of any immediate attempt to assemble, in a work of this kind, more than the barest outlines of the new methods of attack. It is to be hoped, however, that in the next edition it will be possible to include an account of the newer physics which, as yet, is but dimly to be discerned, stirring lightly in the matrices of the new dynamics.

The book is well produced, and the new plates are worthy companions to the beautiful reproductions in the earlier editions. The price has been increased—one serious defect in a book which is in all other respects so well adapted to the needs of the experimental physicist—but no one appreciating the amount of new work incorporated in this edition, or familiar with the cost of production of scientific books, will maintain that the increase is unwarranted. There is an excellent index, of the type (combined author and subject) which ought to be made compulsory in all books on physics.

H. R.

Cell Division.

Das Problem der Zellteilung physiologisch betrachtet. Von Prof. Alexander Gurwitsch. (Monographien aus dem Gesamtgebiet der Physiologie der Pflanzen und der Tiere, Band 11.) Pp. vii+221. (Berlin: Julius Springer, 1926.) 16·50 gold marks.

In this monograph the professor of histology at the University of Moscow puts together the results of a series of researches, carried out in his laboratory, which are so novel in outlook and method of experimental approach that some time must elapse before biologists in general can be prepared to express an opinion upon them. In introductory chapters the problem of cell division is approached in a somewhat artificial semi-philosophical manner, leading up to the general conclusion that the process of cell division is very largely determined as the result of influences received at the surface of the cell.

As possible influences leading to cell division upon reception at the cell surface two are considered: (1) Haberlandt's necro-hormone, a generalised suggestion arising out of experiments which led Haberlandt to think that the meristem divisions giving rise to wound cork were initiated in part as the result of substance diffusing from the wounded cells; (2) the 'mitogenetic' radiations, upon which much work has been done in Gurwitsch's laboratory. The regular cell divisions in the apical meristem of the onion root suggest an influence, inducing cell division, centred within, and radiating from, the apical meristem itself.

Gurwistch then proceeds to test the influence of this 'mitogenetic' radiation, emanating from the root apex, in inducing cell division in the still meristematic region of another root, when the apex of the first root is pointed, at close range, toward the flank of the second root. Normally, in the region behind the apex, when a root is examined, the number of cells found in division on either side of a median line through a longitudinal section is approximately the same. But when, on one side of this median line, the cells have been exposed to this 'mitogenetic' influence of another root apex, many more cells are found in stages of division on this side of the root.

In the main, this general line of experimental evidence is the chief evidence brought forward in support of this very new idea of a mitogenetic radiation. Modifications of the experiment lead to the conclusions that the rays are reflected from a plane glass surface, penetrate quartz, and are probably ultra-violet rays of wave-length between 1900 Å.U. and 2000 Å.U.

A few experiments with root extracts are given as evidence that these rays are released as the result of the interaction of a substance, 'mitotin,' with an enzyme 'mitotase,' on analogy with the phosphorescence of 'luciferin' under enzyme action. The experimental basis given for this conclusion is not, however, very complete. These views of Gurwitsch are given general application to the phenomena of cell division in both animal and plant; it remains to be seen how they will stand the test of time.

Our Bookshelf.

From Tribe to Empire: Social Organisation among Primitives and in the Ancient East. By Prof. A. Moret and G. Davy. Translated by V. Gordon Childe. (The History of Civilisation Series.) Pp. xxx+371. (London: Kegan Paul and Co., Ltd.; New York: Alfred A. Knopf, 1926.) 16*s*. net.

In his foreword, Mr. Henri Berr emphasises the importance of the social factor in history, and points out that in the early volumes of this series, which deals with the evolution of humanity, it has been necessary repeatedly to refer to the problem to which it gives rise. This volume thus marks a critical point in the general scheme of the series. For here we 'come to grips' with the problem. The aim of the book is to introduce the social as such into historical explanation. We find, therefore, that it falls into two parts. In the first part, six chapters introduce the reader to what is known of primitive social development, the material being arranged in a progressive framework. After a statement of the problem, it starts with the totemic organisation in which the individual is lost in the totemic group, or, perhaps it might almost be put, the individual is a function of the totem. It then traces the gradual development of individualised power. This is in effect the centralisation of the magic of the totem, of the land and the community, in one individual, the king. In Part 2 the transition of the clan to the kingdom is considered. This is traced in the early civilisation of Egypt and Mesopotamia. Finally, the working out of the social factor is studied in the first empires of the Orient, and the reader is carried down to the Egypto-Hittite *entente* and the invasion of Egypt by the peoples of the sea in the Nineteenth Dynasty.

The application of primitive sociological data to the elucidation of archæological and historical problems is of course not new, but here it is conceived on a grand scale, and worked out in detail with much ingenuity. A word of caution may not be out of place. In this field much is uncertain, at any rate of early days. It is impossible, for example, to say how great was the extent of the subordination of the individual to the whole. The large generalisations based upon the application of the prevalent analysis to what is often the merest outline, give rise to an uneasy feeling that the interpretation of the more obscure facts has had to square with theory rather than that it has evolved naturally from the facts themselves. In other words, the argument from analogy may have been unduly strained in its application to the internal conditions of Egypt and Mesopotamia.

The Indian Zoological Memoirs on Indian Animal Types. 1: *Pheretima (The Common Indian Earthworm).* By Prof. Karm Narayan Bahl. Pp. iv + 72. (Lucknow: The Methodist Publishing House, 1926.) 1.8 rupees.

A COMMITTEE of zoologists in India has arranged for the preparation of a series of memoirs on the lines of the well-known memoirs published by the Liverpool Marine Biological Committee. Hitherto students of zoology in India, while dissecting Indian types of the various phyla, have had chiefly to use descriptions based on British representatives of those phyla. The present is the first of the series of memoirs on Indian animal types; others are contemplated on a leech, a starfish, a centipede, a scorpion, an ascidian, a dogfish, a catfish, and a lizard.

Prof. Bahl's account of the common Indian earthworm *Pheretima posthuma* sets a worthy standard for the series. The chapters deal successively with the habits and habitat, external features, body wall, cœlom, the alimentary canal, the vascular, excretory, nervous, and reproductive systems, and the development. A concluding chapter contains concise directions for practical work. As would be expected from the author's published papers, the accounts of the vascular and excretory systems are particularly full and well done; perhaps a little less detail in parts of the vascular system would have sufficed. In addition to the examination of the worm by dissection, due attention is devoted to the microscopic study of excised organs and tissues and of transverse sections. The volume is adequately illustrated by two half-tone plates and 29 line drawings in the text.

The author is to be congratulated upon his suggestion that memoirs on common Indian animals should be prepared, and upon his own excellent contribution to the series.

A Book of South African Flowers. By D. Barclay, H. M. L. Bolus and E. J. Steer. Pp. xviii + 174 (57 plates). (Capetown and Johannesburg: The Specialty Press of South Africa, Ltd.; London: L. Reeve and Co., Ltd., 1925) 21*s*.

SINCE its discovery, visitors have been struck by the remarkable flora of Cape Colony, and especially of the particular region known to botanists as the "South-western Region." Here the landscape is often dominated by such unique types of plants as Protea, Leucadendron, Strelitzia, etc., which are found nowhere else in the world. In order to spread a wider knowledge of these interesting and beautiful plants "among those for whom the purely scientific botanical books have little or no meaning," the Wild Flower Protection Society has published a book with illustrations, accompanied by interesting biological notes suitable for the ordinary reader. Most of the plants described are those which were in danger of becoming extinct from various causes, mainly, however, the Capetown flower-seller, and are now protected by law from being destroyed. Thirty-two of these are illustrated by coloured plates, some of them good, some rather poor, and the remainder by photographs. The text has been written by Mrs. Bolus, the Curator of the Bolus Herbarium, Kirstenbosch, the drawings are by Miss Barclay, and the photographs by Mr. Steer. We feel sure not only that the authors' modest hope "that the book may prove useful in schools" will be fulfilled, but also that it will be just the thing for those interested in the Cape flora generally, and especially for the visitor with limited time who wishes to know something about the wild plants around him.

Practical Microscopy: an Introduction to Microscopical Methods. By Dr. F. Shillington Scales. Third edition. Pp. ix + 332. (London: Baillière, Tindall, and Cox, 1926.) 8*s*. 6*d*. net.

IN this third edition the author (whom death has recently claimed) has revised the text and introduced much new matter, particularly in the chapters dealing with the design of the microscope, choice of an instrument, objectives and accessories, and many of the newest models and pieces of apparatus are illustrated. The chapter on the practical optics of the microscope is exceedingly good, and gives all the essentials of the subject in simple form. A chapter on photo-micrography is included. The section on microscopical technique gives an excellent summary of the essentials of the subject—fixing, hardening, section cutting, staining and mounting—and the budding microscopist will find that it will carry him a long way in his work. Tables, formulæ, and a useful bibliography are included in an appendix. R. T. H.

The Goodness of Gods. By Prof. Edward Westermarck. (The Forum Series.) Pp. vi + 58. (London: Watts and Co., 1926.) 1*s*. net.

DR. WESTERMARCK's contribution to the "Forum Series" consists of four chapters in which he follows up the development of the idea of god from its earliest beginnings among primitive peoples in the belief in supernatural beings, to its fully developed form in the higher religions, the religion of the ancient Egyptians, Zoroastrianism, the Vedic religion, Christianity, and Mohammedanism. In the final chapter, "The Betterment of the Gods," the author deals specifically with the ethical side of his theory. The treatment in so small a compass is necessarily concise, and the reader is referred for the data upon which Dr. Westermarck's views are based to his "Origin and Development of the Moral Idea."

Letters to the Editor.

The Scattering of Electrons by a Single Crystal of Nickel.

In a series of experiments now in progress, we are directing a narrow beam of electrons normally against a target cut from a single crystal of nickel, and are measuring the intensity of scattering (number of electrons per unit solid angle with speeds near that of the bombarding electrons) in various directions in front of the target. The experimental arrangement is such that the intensity of scattering can be measured in any latitude from the equator (plane of the target) to within 20° of the pole (incident beam) and in any azimuth.

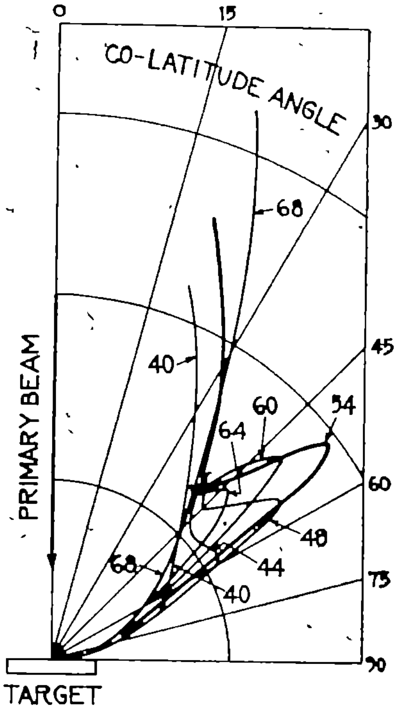

Fig. 1.—Intensity of electron scattering vs. co-latitude angle for various bombarding voltages—azimuth-{111}-330°

The face of the target is cut parallel to a set of {111}-planes of the crystal lattice, and etching by vaporisation has been employed to develop its surface into {111}-facets. The bombardment covers an area of about 2 mm.^{2} and is normal to these facets.

As viewed along the incident beam the arrangement of atoms in the crystal exhibits a threefold symmetry. Three {100}-normals equally spaced in azimuth emerge from the crystal in latitude 35°, and, midway in azimuth between these, three {111}-normals emerge in latitude 20°. It will be convenient to refer to the azimuth of any one of the {100}-normals as a {100}-azimuth, and to that of any one of the {111}-normals as a {111}-azimuth. A third set of azimuths must also be specified; this bisects the dihedral angle between adjacent {100}- and {111}-azimuths and includes a {110}-normal lying in the plane of the target. There are six such azimuths, and any one of these will be referred to as a {110}-azimuth. It follows from considerations of symmetry that if the intensity of scattering exhibits a dependence upon azimuth as we pass from a {100}-azimuth to the next adjacent {111}-azimuth (60°), the same dependence must be exhibited in the reverse order as we continue on through 60° to the next following {100}-azimuth. Dependence on azimuth must be an even function of period $2\pi/3$.

In general, if bombarding potential and azimuth are fixed and exploration is made in latitude, nothing very striking is observed. The intensity of scattering increases continuously and regularly from zero in the plane of the target to a highest value in co-latitude 20°, the limit of observations. If bombarding potential and co-latitude are fixed and exploration is made in azimuth, a variation in the intensity of scattering of the type to be expected is always observed, but in general this variation is slight, amounting in some cases to not more than a few per cent. of the average intensity. This is the nature of the scattering for bombarding potentials in the range from 15 volts to near 40 volts.

At 40 volts a slight hump appears near 60° in the co-latitude curve for azimuth-{111}. This hump develops rapidly with increasing voltage into a strong spur, at the same time moving slowly upward toward the incident beam. It attains a maximum intensity in co-latitude 50° for a bombarding potential of 54 volts, then decreases in intensity, and disappears in co-latitude 45° at about 66 volts. The growth and decay of this spur are traced in Fig. 1.

A section in azimuth through this spur at its maximum (Fig. 2—Azimuth-330°) shows that it is sharp in azimuth as well as in latitude, and that it forms one of a set of three such spurs, as was to be expected. The width of these spurs both in latitude and in azimuth is almost completely accounted for by the low resolving power of the measuring device. *The spurs are due to beams of scattered electrons which are nearly if not quite as well defined as the primary beam.* The minor peaks occurring in the {100}-azimuth are sections of a similar set of spurs that attains its maximum development in co-latitude 44° for a bombarding potential of 65 volts.

Thirteen sets of beams similar to the one just described have been discovered in an exploration in the principal azimuths covering a voltage range from 15 volts to 200 volts. The data for these are set down on the left in Table I. (columns 1-4). Small corrections have been applied to the observed co-latitude angles to allow for the variation with angle of the 'background scattering,' and for a small angular displacement of the normal to the facets from the incident beam.

If the incident electron beam were replaced by a beam of monochromatic X-rays of adjustable wave-length, very similar phenomena would, of course, be observed. At particular values of wave-length, sets of three or of six diffraction beams would emerge from the incident side of the target. On the right in Table I. (columns 5, 6 and 7) are set down data for the ten sets of X-ray beams of longest wave-length which would occur within the angular range of our observations. Each of these first ten occurs in one of our three principal azimuths.

Several points of correlation will be noted between the two sets of data. Two points of difference will also be noted; the co-latitude angles of the electron beams are not those of the X-ray beams, and the three electron beams listed at the end of the Table appear to have no X-ray analogues.

The first of these differences is systematic and may be summarised quantitatively in a simple manner. If the crystal were contracted in the direction of the incident beam by a factor 0·7, the X-ray beams would be shifted to the smaller co-latitude angles θ′ (column 8), and would then agree in position fairly well with the observed electron beams—the average difference being 1·7°. Associated in this way there is a set of electron beams for each of the first ten sets of X-ray beams occurring in the range of observations, the electron beams for 110 volts alone being unaccounted for.

These results are highly suggestive, of course, of the ideas underlying the theory of wave mechanics, and we naturally inquire if the wave-length of the X-ray beam which we thus associate with a beam of electrons is in fact the h/mv of L. de Broglie. The comparison may be made, as it happens, without assuming a particular correspondence between X-ray and electron beams, and without use of the contraction factor. Quite independently of this factor, the wave-lengths of all possible X-ray beams satisfy the optical grating formula $n\lambda = d \sin \theta$, where d is the distance between lines or rows of atoms in the surface of the crystal—these lines being normal to the azimuth plane of the beam considered. For azimuths {111} and {100}, $d = 2{\cdot}15 \times 10^{-8}$ cm. and for azimuth {110}, $d = 1{\cdot}24 \times 10^{-8}$ cm. We apply this formula to the electron beams without regard to the conditions which determine their distribution in co-latitude angle. The correlation obtained by this procedure, between wave-length and electron speed v is set down in the last three columns of Table I.

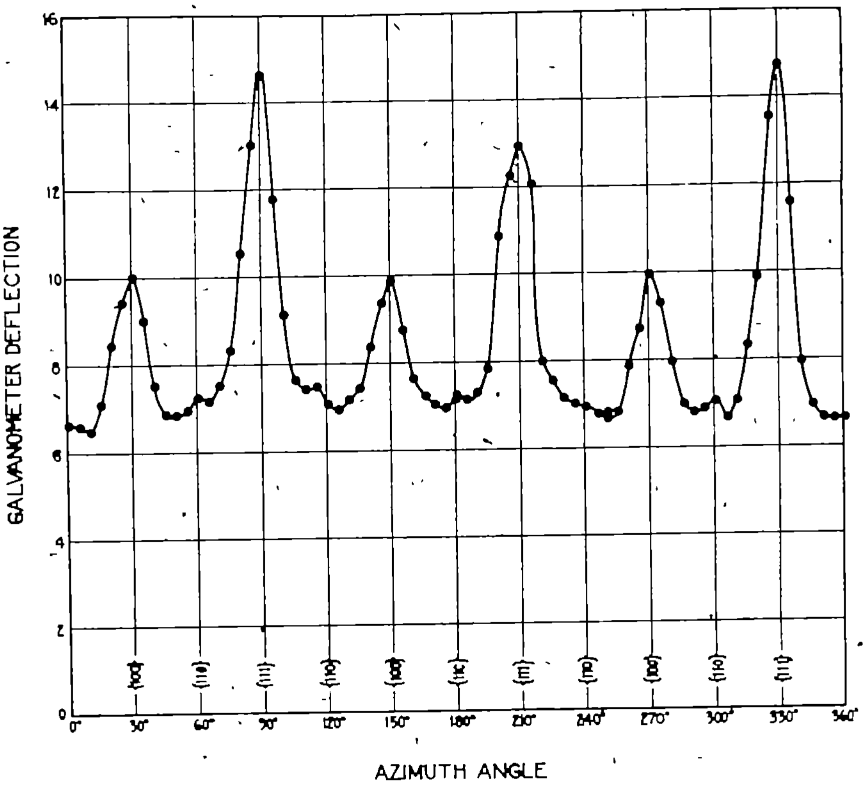

Fig. 2—Intensity of electron scattering vs. azimuth angle—54 volts, co-latitude 50°.

Table I.

	Bomb. Pot (volts)	Co-lat. θ.	Intensity.	Reflections.	λ × 10⁸ cm.	Co-lat θ.	Co-lat. θ′.	$v \times 10^{-8}$ cm./sec.	$n\lambda \times 10^8$ cm.	$n\left\{\frac{\lambda mv}{h}\right\}$.
{111}	54 100 174	50° 31 21	0·5 0·5 0·9	{220} {331} {442}	2·03 1·49 1·13	70·5 44·0 31·6	52·7 31·6 22·4	4·36 5·94 7·84	1·65 1·11 0·77	0·99 0·91 0·83
	174	55	0·15	{440}	1·01	70·5	52·7	7·84	1·76	2(0·95)
{100}	65 126 190	44 29 20	0·5 1·0 1·0	{311} {422} {533}	1·84 1·35 1·04	59·0 38·9 28·8	43·2 27·8 20·4	4·79 6·67 8·19	1·49 1·04 0·74	0·98 0·95 0·83
	159	61	0·4	{511}	1·05	77·9	59·0	7·49	1·88	2(0·97)
{110}	138 170	59 46	0·07 0·07	{420} {531}	1·22 1·04	78·5 57·1	59·5 41·7	6·98 7·75	1·06 0·89	1·02 0·95
{111} {100} {110}	110 110 110	58 58 58	0·15 0·15 0·25	. . . . . .	. . . . . .	. . . . . .	. . . . . .	6·23 6·23 6·23	1·82 1·82 1·05	1·56 1·56 0·90

In considering the computed values of $n(\lambda mv/h)$, listed in the last column, we should perhaps disregard those for the 110-volt beams at the bottom of the Table, as we have had reason already to regard these beams as in some way anomalous. The values for the other beams do, indeed, show a strong bias toward small integers, quite in agreement with the type of phenomenon suggested by the theory of wave mechanics. These integers, one and two, occur just as predicted upon the basis of the correlation between electron beams and X-ray beams obtained by use of the contraction factor. The systematic character of the departures from integers may be significant. We believe, however, that this results from imperfect alignment of the incident beam, or from other structural deficiencies in the apparatus. The greatest departures are for beams lying near the limit of our co-latitude range. The data for these are the least trustworthy.

The Brain of Laplace.

The bicentenary of the death of Newton (March 20, 1727) is within a fortnight of the centenary of the death of Laplace (March 5, 1827), and no one acquainted with the work of both can think of one or other except in association. It may, therefore, not be an unfitting occasion to refer to an historical point with regard to the great Frenchman, when we are celebrating the great Englishman.

The physiologist and anatomist Magendie propounded the theory that the intelligence of a human being was in the inverse ratio of the amount of cerebro-spinal fluid contained in the brain case. Writing in 1827, the year of Laplace's death, his "Mémoire physiologique sur le cerveau,"[1] he inserted the following words:

> "Je me suis trouvé dans la douloureuse nécessité d'examiner le cerveau d'un homme de génie mort dans un âge avancé, mais jouissant encore de la plénitude de ses facultés intellectuelles; la somme totale du liquide céphalo-spinal ne s'élevait pas à deux onces, et les cavités du cerveau en contenaient à peine un gros" [$=\frac{1}{8}$ once].

I have been unable so far to find any further reference in the writings of Magendie "to the brain of this man of genius who died at an advanced age" and in the fullness of his intellectual powers. Magendie appears to have given no further account of this brain; at least I have found none. Laplace died at the age of seventy-eight in the year Magendie wrote. I have also failed to discover any minute record of Laplace's death which would suggest that an autopsy was made or was a "douloureuse nécessité." I would venture, therefore, to ask those who may be better acquainted than I am with the circumstances of Laplace's death to let me know why his brain came into Magendie's possession and whether a full report on it was ever written. Magendie, indeed, mentions no name, and this might lead one to consider his investigation of the matter was confidential. However, I think the ascription is certain, for quite recently Miss Helen Hunter Baillie—a lady who combines the blood of other famous anatomists with that of a famous author,[2] placed in the hands of Miss Miriam Tildesley a letter of Joanna Baillie to her great niece Miss Sophy Milligan. This letter, dated Hampstead, Monday, 1834, contains the following important paragraph:

> "My dear Sophy. . . . Dr. Somerville told us not long ago a whimsical circumstance regarding the head of La Place, the famous French astronomer. Some Ladies and Gentlemen went one day to the house of Majendie (sic!), the great anatomist, to see the brains of this Philosopher which they conjectured must be of a very ample size, and seeing a preparation on the table answering their expectation they were quite delighted. 'Ah! see what a superb brain, what organs, what developments! This accounts completely for all the astonishing power of his intellect, etc.' Majendie, who was behind them and overheard all this, stepped quietly forward and said: 'Yes, that is indeed a large brain, but it belonged to a poor Idiot, who when alive scarcely knew his right hand from his left. This, Ladies and Gentlemen' (handing to them a preparation of a remarkably small brain), 'this is the brain of La Place.' Dr. Somerville was told this anecdote by Majendie himself. . . .
>
> Your affectionate Aunt, J. Baillie."

This Dr. Somerville can scarcely be other than the physician, fellow of the Royal Society, and husband of Mary Somerville, the learned lady who studied Newton's "Principia" in the original, was the correspondent of Laplace, and paraphrased his "Mécanique Céleste." There can thus be no doubt that Magendie was in possession of the brain of Laplace, and very little doubt that the passage in the "Mémoire physiologique sur le cerveau," written 1827, refers to that brain. The questions I would put to the French readers of Nature are these: What became of Magendie's preparations? Have they, and with them Laplace's brain, survived until to-day? If so; has any one reported on it, or does any account by Magendie other than that I have cited, written or printed, exist? So few brains of great thinkers have been available for examination, that it would be a real disaster if Laplace's should have had only four lines devoted to it.

The Microscopical Examination of Flint Surfaces.

During the course of my work in the experimental fracture of flint by (*a*) human blows delivered by a hammer-stone, (*b*) unguided percussion, (*c*) unguided pressure, and (*d*) the application of heat, it became, in my opinion, possible, by a close examination of an extensive series of each of the differing types of flaking produced by these various methods of fracture, to differentiate between the work of man, and that of Nature ("Pre-Palæolithic Man," W. E. Harrison, publisher, Ipswich). While engaged upon this research I was much interested to notice that not only the type of flaking of the different series served to distinguish them from each other, but also that this difference appeared to find support, though in a less obtrusive manner, *in the appearance of the surface of the flints* broken by the methods above enumerated.

Most of those who are familiar with fractured flints of prehistoric date will have probably noticed the marked differences, often observable to the naked eye, between, for example, specimens broken by thermal effects and others fractured by human blows. The surfaces of the flake-scars of the former exhibit, generally, a much duller, less bright, surface than those of the latter. It occurred to me that this difference was caused possibly by the fact that these surfaces differed in texture, and had thus offered a differing resistance to the natural force, or forces, responsible for the imposition of 'polish,' or 'gloss," upon the flake-scars of fractured flints. Further, it seemed highly probable that this difference in texture, if it existed, would have been most likely to have been produced by the two differing forms of fracture, and I compared, provisionally, the surfaces of a flint broken by thermal effects, to those of an apple which has been pulled in half with the hands and exhibits a rough surface, while I likened the surfaces of the flake-scars of the flint broken by human blows to the smooth surface of an apple cut in half by a knife.

---

[1] Published by Magendie in his own *Journal de Physiologie expérimentale et pathologique*, Tome 8, p. 228, 1828.

[2] The mother of Joanna Baillie was sister of William and John Hunter.

In order to make some test of this theory, I procured examples of good, sound flint from the detritus-bed at the base of the Red Crag of Suffolk, and having fractured some by means of a hammer-stone, and others by putting them into a fire, thus producing flake-scars by (*a*) human blows and (*b*) thermal effects, I had photo-micrographs taken of the two surfaces in order to see if they differed in appearance. A number of specimens were examined and photographed, and the surfaces here illustrated (Figs. 1 and 2) may, I think, be said with fairness to be typical. Fig. 1 shows the type of surface produced by human blows, while Fig. 2 illustrates the type of surface produced by thermal fracturing. An examination of these illustrations will show that the two surfaces differ from each other, and that this difference takes the form of the greater or lesser number, and prominence, of the white markings visible on the photographs.

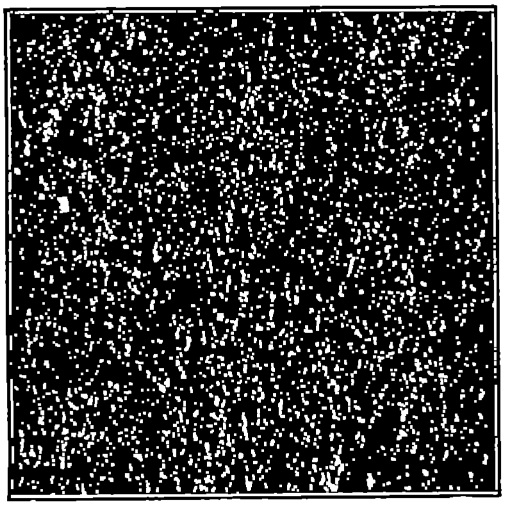

FIG. 1.—Photo-micrograph of surface of flint fractured by human blows. (×100)

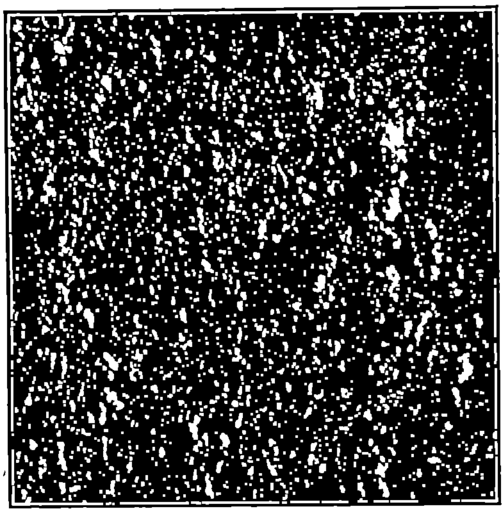

FIG. 2.—Photo-micrograph of surface of flint fractured by thermal agency. (×100.)

Though it is possible that these markings point to the 'thermal' surface being rougher than that produced by human blows, yet this is by no means certain. In fact, I am unable at present to say what these markings actually represent. But I believe that, though illustrating such a small area of the flint under examination, the photographs are representative of the two types of surface mentioned, and that the differences here indicated, plus the well-known other divergences between the flake-scars formed by human blows and thermal effects, now make it possible to differentiate, with confidence, between them.

I conceive that differences, though less easily observable, may exist between the surfaces of flints fractured by human blows and natural pressure, but so far I have not been able to establish this very important fact to my satisfaction. I believe, however, that this method of attempting to ascertain the manner in which a flint has been broken, though novel, has great possibilities before it, and will lead to very definite and valuable scientific results.

Haze.

WITH regard to the composition of the haze which often obstructs visibility in the summer, the following experiments may be of interest owing to the curious results and the make-shift methods which had to be used.

In August last, while staying on the coast of Norfolk, a well-marked haze appeared covering the whole country on Aug. 31 and Sept. 1. This had the characteristic bluish look often seen in summer haze. There was at the same time a strong wind blowing from the sea from north-west by north, which on Sept. 1 veered to nearly due north, the velocity being nearly 20 m.p.h. as measured by the flight of thistledown over a measured distance. The sea was rough, and the haze was such that the limit of visibility was about 5 miles.

Having no instruments with me with which to obtain samples of this haze, an instrument was improvised as shown on the sketch (Fig. 1). An empty peach tin 100 mm. diameter had a hole about 2 mm. diameter made in the centre of the bottom. The tin, A, was lashed to a piece of board with string, the bottom being brought up against a step, B, cut on the edge of the board; a microscope slide, C, was fixed opposite the hole in the bottom of the tin by means of a wedge, W, between it and the tin. This wedge also served the purpose of adjusting the distance between the slide and the hole to about 2 mm. The board carrying the tin was attached to a stake about 4 ft. 6 in. high, which was fixed in the ground with the mouth of the tin facing the wind.

A clean slide having been placed in position behind the tin, a definite patch became visible in 45 minutes on the glass opposite the hole, where the jet of air produced by the hole struck the slide. It was left in position for a little more than an hour, when the slide was removed and another put in its place which also received a patch visible to the naked eye. These patches, on examination under the microscope, were found to consist of a mixture of drops of liquid and crystals. The first consisted almost entirely of drops when examined, the relative humidity at the time being 82 per cent.

On warming gently all the drops dried, leaving crystals mostly of a skeletal form with branches at 90°, but some were cubical, while a few were thin rhomboidal plates, and these latter did not deliquesce as the others did when the slide cooled. The second slide was similar, except that there were in the drops larger numbers of rhomboidal crystals which showed no tendency to deliquesce, while on warming the slide numbers of cubical crystals appeared, with sides up to 24 μ, clearly of common salt; also a number of skeletal crystals with 90° arms (Fig. 2). It would appear, therefore, that this haze consisted almost entirely of crystalline salts, existing partly in the solid and partly in the deliquesced condition, and presumably mainly derived from sea spray, with crystals, probably sulphates, derived from the smoke of cities on the north-east coast. With such a dense supply of hygroscopic crystalline matter in the air it would seem certain that a liquid fog would result from the deliquescence of the crystals present long before saturation, indeed probably in the neighbourhood of 70 per cent. relative humidity. Fig. 2.

Hereditary Choice of Food Plants in the Lepidoptera and its Evolutionary Significance.

Mr. Edward Meyrick, in his comments (Nature, Mar. 12) upon my paper (*Proc. Roy. Soc.*, B, vol. 101, pp. 115-127) on the egg-laying instincts of *Pontania salicis*, so completely misses the point that it is difficult to deal with them seriously. The "new principle" to which he refers does not depend in the slightest upon the work he mentions, but is deduced from work described in an earlier paper (*Proc. Roy. Soc.*, B, vol. 99). It may be summed up in two sentences: (1) Chemical agencies acting through ingested food have been shown to act directly on the germ plasm so as to affect its potentialities; (2) Therefore any circumstance bringing about a change in the food ingested by an organism may affect its germ plasm so as to produce heritable variations.

Independently of this failure to appreciate the real foundation of the new principle, several other remarks of Mr. Meyrick require criticism. Amongst these is the statement that the only discrimination made by Salix-feeding Lepidoptera is in general between rough- and smooth-leaved species, and with this is coupled the remark that the influence determining the choice is touch rather than taste. Such views could not possibly emanate from one who has studied the matter in the field. I have recently been investigating the egg-laying habits of the moth *Ypsipetes ruberata*, which abounds here in a tangle of *Salix pentandra* and *S. aurita*. I can assure Mr. Meyrick that the females, when intent on egg-laying, never approach the *S. pentandra* to test the roughness of its foliage, but fly directly to the leaves of *S. aurita*. Moreover, I fail to see how their smoothness or the reverse can affect the choice of food-plant in the case of the lepidopterous *Xanthia flavago*, the coleopterous *Cryptorhynchus lapathi*, or the various Cecidomyids of the genus Rhabdophaga, which, with many other species, lepidopterous and otherwise, favour *S. aurita* in the same thicket but lay their eggs on the bark! The facts are, of course, that the two species of Salix support two very different faunas.

Further, Mr. Meyrick cannot really imagine that I think that the species employed as examples of allied pairs originated in Britain? I am quite well aware of their range outside our limits, but fail to grasp what this, or the exact locality in which they originated, has to do with the argument. Again, he seems to imply that I consider that a new species has been originated in three generations. No one ever claimed this; the experiments criticised dealt with only one point, that of egg-laying habits. Nevertheless, had Mr. Meyrick understood the principle, or the precise experiments upon which it was based, he would have realised, as is clearly stated in my paper but overlooked by him, that under its workings *Selenia bilunaria* diverged from the parent stock in wing colour and shape, length of larval life, and other features. These achievements may not, in Mr. Meyrick's eyes, go far to explain species-formation in the Lepidoptera, but still they do show how breaks from the original species arise which, in the end, may yield new species. One can expect little more in the lifetime of one worker!

Mr. Meyrick is correct in saying that entomologists have long noted that groups of related species feed on allied or associated plants and probably arose as phytophagous races. However, recognition of these facts is one thing, and an explanation on an experimental basis is another; this explanation I have endeavoured to supply.

As Mr. Meyrick speaks very definitely on the lack of variation, except in size, produced by food amongst the very variable, polyphagous British Caradrinidæ, he doubtless has access to experimental work bearing on the point. If so, these experiments are entirely unknown to me, and should be produced for the guidance of fellow-workers. The only pertinent researches on the Caradrinidæ with which I am acquainted are those of Hasebroek (*Zool. Jahrb., Abt. f. allg. Zool. u. Physiol.*, Bd. 37, 1919), and that investigator gives a very definite correlation between the food and certain phases of variation.

In conclusion, I plead for one thing, and that is the removal of the tendency to surround the results of researches in experimental evolution in a cloud of words; what is wanted is not words, but more experiments—and then still more!

Biological Fact and Theory.

IT seems to me that all the facts of genetics must be accepted so far as they are supported by evidence, but the antagonism of some biologists is, I think, chiefly due to the complacency with which geneticists assume and assert that their discoveries explain all the important phenomena of biology, including the evolution of adaptations. Prof. T. H. Morgan believes that change of structure has been due to mutation, and that organisms have adapted their habits accordingly. I know of no case of mutation which is in any way parallel to the metamorphosis of the flat-fish or the frog.

The most crucial test, however, of the claims of genetics is the relation of sex-limited characters to the gonadial hormones. Prof. Morgan's view is that "supposing the testis hormone were the cause of strength and activity in the male which would be preserved and developed by natural selection, their secondary influence over other parts of the body would call for no other explanation." Obviously there is no suggestion here of any reason why the hormone should have a secondary influence over other parts of the body, or what determines the special result of the influence. The antlers of a stag have no essential relation to sex or reproduction at all, any more than its legs. Both legs and antlers are part of its hereditary constitution, but the latter depend for their normal development on the testis hormone, the former do not. Female secondary sexual characters, like the milk glands of mammals, are influenced by ovarian hormones. The only connexion with sex which such organs have is an external one, through function and habits. The antlers are only sexual in the use that is made of them in fighting between rival males. The testis hormone is much the same in all mammals; it is certain that there is nothing in the stag's hormone which would produce antlers in a horse or in a man. Why, then, should organs which have functions related to sexual habits be connected physiologically with the gonads or other reproductive organs?

There is nothing in all the facts of genetics or in the refinements of genetical theory, and nothing known about mutations, which throws light upon the relation of sex-limited characters to the sexual habits on one hand and to the gonads on the other.

J. T. CUNNINGHAM.

35 Wavendon Avenue, W.4,
Mar. 10.

THE discussion in NATURE under the above heading appears to me to be based in large measure upon failure to realise the character of scientific knowledge. Such misunderstanding is to be deprecated as being contrary to the interests of further progress in biology. I beg leave, therefore, to reiterate that scientific hypotheses, otherwise known as laws of Nature, are created by the mind of man for purposes of prediction and generalisation. They do not represent absolute truth, and are always liable to be superseded by new hypotheses which are more widely embracing. The Mendelian laws are no exception. So long as these laws fulfil the function of helping men of science to generalise and to predict they may be held to reflect definite degrees of reality. If, however, they fail to serve this purpose they have no logical justification.

Genes or factors, like atoms and molecules, are concepts invented by the human mind, but if their invention leads to increased complexity of thought rather than to simplification, it is both useless and unwarranted. I am not a geneticist, and to what extent, if any, such a perversion of sound scientific method is being made, it is not for me to say. Nevertheless, I suspect that much of the misunderstanding which has found expression concerning this subject would be resolved by a proper appreciation of the descriptive character of natural science and the limits of its domain.

The Continuous Spectrum of β-Rays.

THE continuous spectrum of the β-rays arising from radio-active bodies is a matter of great importance in the study of their disintegration. Two opposite views have been held about the origin of this continuous spectrum. It has been suggested that, as in the α-ray case, the nucleus, at each disintegration, emits an electron having a fixed characteristic energy, and that this process is identical for different atoms of the same body. The continuous spectrum given by these disintegration electrons is then explained as being due to secondary effects, into the nature of which we need not enter here. The alternative theory supposes that the process of emission of the electron is not the same for different atoms, and that the continuous spectrum is a fundamental characteristic of the type of atom disintegrating. Discussion of these views has hitherto been concerned with the problem of whether or not certain specified secondary effects could produce the observed heterogenity, and although no satisfactory explanation has yet been given by the assumption of secondary effects, it was most important to clear up the problem by a direct method.

There is a ready means of distinguishing between the two views, since in one case a given quantity of energy would be emitted at each disintegration equal to or greater than the maximum energy observed in the electrons escaping from the atom, whereas in the second case the average energy per disintegration would be expected to equal the average energy of the particles emitted. If we were to measure the total energy given out by a known amount of material, as, for example, by enclosing it in a thick-walled calorimeter, then in the first case the heating effect should lead to an average energy per disintegration equal to or greater than the fastest electron emitted, no matter in what way this energy was afterwards split up by secondary effects. Since on the second hypothesis no secondary effects are presumed to be present, the heating effect should correspond simply to the average kinetic energy of the particles forming the continuous spectrum.

To avoid complications due to α-rays or to γ-rays from parent or successive atoms, we measured the heating effect in a thick-walled calorimeter of a known quantity of radium E. This measurement proved difficult because of the small rate of evolution of heat, but by taking special precautions it has been possible to show that the average energy emitted at each disintegration of radium E is 340,000±30,000 volts. This result is a striking confirmation of the hypothesis that the continuous spectrum is emitted as such from the nucleus, since the average energy of the particles as determined by ionisation measurements over the whole spectrum gives a value about 390,000 volts, whereas if the energy emitted per disintegration were equal to that of the fastest β-rays, the corresponding value of the heating would be three times as large—in fact, 1,050,000 volts.

Many interesting points are raised by the question of how a nucleus, otherwise quantised, can emit electrons with velocities varying over a wide range, but consideration of these will be deferred until the publication of the full results.

The Coefficient of Ionisation of a Fused Salt.

IT is now forty years since Arrhenius and Van't Hoff put forward two independent methods for calculating the 'coefficient of ionisation' of a dissolved salt. The general concordance of their results provided a firm foundation for Arrhenius's theory of electrolytic dissociation, whilst the smaller discordances have provided material for the development of the later theory of complete ionisation. Since neither of the above methods could be used to determine the coefficient of ionisation of a fused salt, it has been supposed that the problem of determining this coefficient was insoluble. All the data that are required for a formal solution are, however, available for silver chloride at 600°, namely, molecular weight $M = 143{\cdot}34$, density $\delta = 5{\cdot}267 - 0{\cdot}00092\,t = 4{\cdot}715$, specific conductivity $\kappa = 4{\cdot}48$, viscosity $\eta = 0{\cdot}01606$ (at 603°).

The normality of the fused salt is $4715 \div 143{\cdot}34 = 32{\cdot}9\,N$; and the equivalent conductivity $\Lambda = 4{\cdot}48 \div 0{\cdot}0329 = 136$. A value for the equivalent conductivity, Λ_∞, of the completely ionised salt, can be deduced from the value in aqueous solutions, for which $\Lambda_\infty^{18} = 54 + 65 = 119$, by making a proportional correction for the increase of viscosity from 0·01056 to 0·01606; the value thus deduced is 78. Since, however, aqueous solutions are often abnormal, more importance attaches to a value deduced from Walden's relation, $\Lambda_\infty \eta_\infty \sqrt{M} = 11{\cdot}15$, which has been verified for six salts in 29 non-aqueous solvents, as well as for two 'anhydrous' salts in aqueous solution. For silver chloride, $\Lambda_\alpha = 11{\cdot}15 \div 0{\cdot}01606 \div 12 = 58$. The formal values for $\alpha = \Lambda/\Lambda_\infty$ are then $136 \div 78 = 1{\cdot}74$ and $136 \div 58 = 2{\cdot}35$.

Results such as these, indicating an ionisation of about 200 per cent., have perhaps been deduced before, but have been thought to be too absurd to justify publication. They represent, however, an anomaly which merits consideration. The view that *the ions of the solvent* exhibit an exceptionally great mobility may be true of water, but is certainly not true of other solvents, and cannot therefore be used as a general explanation of the high conductivity which is characteristic of many fused salts. It is therefore more plausible to attribute this effect to the presence of multiply-charged ionic aggregates, resembling the 'ionic micelle' of a colloidal electrolyte, since these would increase both the viscosity and the conductivity of the liquid.

Larger Aspects of Natural Selection.

THE brilliant researches of Harrison and Garrett, wherein they succeeded in producing heritable modifications in geometrid moths by the use of lead nitrate and manganese sulphate, suggest some reflections on the relation of these phenomena to natural selection. In 1908 I wrote (*Popular Science Monthly*, Dec. 1908, p. 547): "Speaking philosophically, progressive or orthogenetic evolution—the existence of which no naturalist has any ground for doubting—must have a cause external to itself. All probability favours the idea that this did not operate once for all, but has continued in action throughout the ages. It may be found, perhaps, in the susceptibility of the hereditary mechanism to environmental influences of particular kinds, the nature of which remains for the present obscure. These reactions would fall under the operation of natural selection from the very beginning; thus a too susceptible organism would quickly be thrown out of gear and would perish; a too conservative one, unless adapted to practically unchanging types of life, would equally perish. There would be a certain optimum susceptibility, which would be preserved, and would differ for different groups. More than this, certain kinds of susceptibility would be favoured, and being once developed might, like bad habits, become harmful through the accumulation of results, resulting in extinction."

Suppose that we think of mutations as chemical changes induced by certain agents, there is apparently no reason why any of them should be adaptive, or, as we say, 'purposeful.' Yet if we think of millions of such changes, occurring during millions of years, it is evident that natural selection must operate to sort out those substances the reactions of which are more or less likely to be beneficial. This process would not go beyond a certain point, because from the viewpoint of natural selection, it is the race and not the individual that matters. If once in a hundred or a thousand times a favourable reaction occurred, that might suffice; but if it never occurred, the line would probably eventually die out. There is thus some reason for expecting a higher percentage of favourable variations than would be expected on purely chemical grounds.

The Control of the Beat of the Fan Segments in *Chætopterus variopedatus*.

WHILE studying regeneration in the tubiculous polychæt *Chætopterus variopedatus* (Renier), some observations were made of a different nature on the rhythmically beating fan segments.

In this worm there are three such segments which beat in a co-ordinated manner, producing a strong current through its tube. The most anterior seems to act as the pacemaker and half accomplishes its beat before the middle fan starts, and this in turn is similarly in advance of the posterior fan. This sequence persists even when the three segments are together isolated from the rest of the worm, but when isolated from each other they beat independently.

In each segment the ganglion is bilobed and the system of muscles, radial and circular, is bilaterally arranged. The intersegmental tissue is greatly constricted and the segments may readily be isolated with little injury, while the ganglion may be extirpated with a needle entirely or on one side only. When destroyed on both sides the contractions cease, but if on one side, the contractions of that side only are stopped, the other side continuing to beat in a relatively normal manner.

The anatomy of these structures has been described in detail by Joyeux-Laffuie (*Arch. Zool. exp. et gén.*, 8, p. 244; 1890). Thus each half of a fan segment acts as a single nerve muscle system under the control of the corresponding half of the ganglion, the action of which, however, is synchronised with that of the other, while the whole is subordinated, in the case of two out of three, to the influence of the segment immediately in front of it.

A further point of interest is that such isolated fan segments may readily be kept alive and beating in a stream of well-aerated sea water for four or five weeks, and so form promising material for further experimental work.

Numerical Solution of Algebraic Equations.

In his account of Newton's work in pure mathematics (Nature, Mar. 26, Suppt. p. 42), Prof. Mordell directs attention to the method of solving the cubic equation introduced by him. This method is in principle precisely that usually attributed to Horner; but the form quoted by Prof. Mordell is much more convenient in application than that given in most modern works on algebra. In the original form of the method, when we want to reduce the equation by 2, we replace y by $p+2$, and rearrange in powers of p. In the usual form we divide three times by $y-2$; thus in finding the coefficient of the second term we add 2 to the original coefficient three times instead of simply adding 6. The introduction of division resulted in a great increase in labour instead of a reduction. If there is any doubt, try it both ways and see!

The device of multiplying the roots by 10 is also, I think, undesirable, but less so. I have found it easier to dispense with it, noticing when the highest term has become too small to affect the answer. The whole equation should be multiplied by a power of 10 at intervals, so as to keep the coefficient of the *first* power of the unknown between 1 and 10.

Last year I had occasion to mark a number of solutions of a cubic equation produced in an examination. They included, to my surprise, a number by Tartaglia's method, which were almost as short as those obtained by the Newton-Horner method at its best. Tartaglia's method, of course, replaces the problem of solving the cubic by that of finding two cube roots, and in the absence of tables the extraction of one cube root is as difficult as the solution of the original equation. But tables of logarithms avoid this difficulty. For numerical work the disadvantages of Tartaglia's method, using tables, are first, that it does not work in the "irreducible case," and second, that it is not a particular case of a general method applicable to equations of all degrees.

Harold Jeffreys.

St. John's College, Cambridge.

Behind the Divining Rod.

I do not quite understand why Dr. Mill should assume (Nature, Mar. 26, p. 458) that the dowsers of my acquaintance are 'ignorant charlatans,' and they certainly have never 'impudently challenged' my studies, scientific or not. For my own part I regard these honest folk simply as self-deluded enthusiasts, and trust that no one will see in this a euphemistic equivalent; I am quite sure that at least one of my scientific friends would feel hurt if the term 'ignorant charlatan' were applied to his pet dowser.

It is fortunate that Dr. Mill knows an honest man of whose powers he is convinced. Here there is good material for serious investigation. Experiments might be devised to determine whether the subject responded to the influence of flowing water, but fortunately stationary metals, such as gold or silver, could be substituted for flowing water. This would simplify the procedure. I would suggest that a handful of similar coins, say French francs, which resemble gold, and English sovereigns, should be shuffled and then distributed into wooden boxes, all of the same size and outward appearance. The whole operation to be so conducted that the investigator himself should be ignorant of the location of the genuine noble metal and its simulacrum. This would exclude any telepathic influence. Should the dowser by 'spotting' the sovereigns emerge successfully from this test, there would then be good grounds for extended inquiry.

I may add that I am familiar with the one-sided presentation of the question which we owe to the advocacy of the late Sir William Barrett, and am unable to regard its evidence as convincing.

W. J. Sollas.

University Museum, Oxford,
Mar. 27.

Prof. Carl Runge.

Many of those who attended the meeting of Section A of the British Association at Oxford last August, distinguished as it was by the presence of so many spectroscopists and atomic theorists from various countries, will remember the peculiar pleasure, and one might say affection, roused by a really beautiful speech from that veteran mathematical spectroscopist, Prof. Runge; in which he expressed gratification at the brilliant results which were pouring forth on all sides as the outcome of earlier work in which he and some German colleagues had taken a leading part. In the peroration of that speech he pronounced on himself a touching *Nunc Dimittis*, which, alas, only five months later has been justified, though, as we learn from the obituary notice in Nature of April 9, p. 533, he had attained only seventy-one years of age.

Surely Runge felt the welcome which we gave him; and I will only quote, without comment, the concluding words of that obituary notice: "His son was killed early in the War."

Oliver Lodge.

April 9.

The Behaviour of Cultures of *Leishmania* sp. in *Phlebotomus papatasii*.

We must apologise for two errors in the note on the behaviour of cultures of Leishmania in *P. papatasii* (Nature, Jan. 8, p. 48). Sandfly No. 172 was not laboratory bred but was caught in Jerusalem, but as the infection rate in sandflies in Jerusalem is either nil or so small as to be negligible (not a single example of an infection was found during two years' dissection), this makes no difference to the conclusions deduced from the experiment. The inoculation was performed on Sept. 20, and not Sept. 26.

Philosophical Foundations of Quantum Theory.[1]

By Dr. P. Jordan, University of Göttingen.

The development of physics in the last decades has repeatedly raised epistemological questions of fundamental importance. Thus in the theory of relativity the problem of space and time received at least a temporary clarification. New questions have arisen in connexion with the quantum theory, and particularly the question of the existence of causal laws in elementary physical processes. Is the condition of an atomic system completely determined, or are there gaps in its determination?

Physicists no longer doubt that this question of the existence of a complete causal determination can only be settled by experience, and that causality is not an *a priori* necessity of thought. Certainly some degree of determinism is an essential condition for the possibility of physical science, as it is for any ordered and intelligible existence; and fortunately we have, if we confine ourselves to macroscopic phenomena, an apparently universal and trustworthy determinism. But for atomic phenomena this implies only a statistical determinism. The question of the causal necessity of the laws of an individual atom thus remains.

Before we attack this point it will be useful to give the notion of determinism a more precise consideration. The physicist cannot be satisfied with the approximate idea that we have of the meaning of this word. Nor is he interested in the metaphysical significance that some philosophers give it. For the physicist the definition of causality or determinism means the specification of conditions by which its existence may be experimentally established. This shows that the physical definition must continually change in accordance with the basis of our theories and facts and experimental methods. Let us consider first the rôle of causality in the classical physics of the field.

The contention of this classical physics is that the physical world may be described—and we use the word describe in a more or less purely geographical sense—by the specification of certain measurable quantities—fields, potentials, etc.—for every point of a four-dimensional region of space-time; and then the causal determinism consists in this. Let us consider a bounded volume of the space—say a parallelepiped. We shall not consider what modifications would be introduced into these considerations by taking complete account of the relativistic relations of space and time; but this would, of course, raise no difficulty. At a certain time—for example, at eleven o'clock—let the physical conditions inside the box be completely known and measured. Further, let the physical conditions of the entire surface of the box be specified from eleven until twelve o'clock. The physical phenomena in the whole box will then be uniquely determined from eleven to twelve o'clock. Thus, if we at any other time and place repeated the experiment, with the same initial conditions and the same course for the surface conditions, all of the phenomena inside the box would automatically be reproduced. Within a certain period of time—of the order of magnitude of the dimensions of the box divided by the velocity of light—the phenomena inside the box are independent of those on the surface.

These assertions are susceptible of experimental proof. Of course, we have to suppose at the beginning that the initial state within the box is not so complicated that its complete physical investigation would be entirely impossible. Thus we should have to exclude the case that there is a living organism in the box; for the notion that one could measure exactly the physical conditions is in this case not in accord with the experimental practicability. Thus the notion of determinism must be formulated differently for biology and for physics.

Let us therefore confine ourselves to a consideration of physical determinism. We may remark that this determinism is of an extraordinary kind; it is not at all equivalent to the mere existence of physical laws—the existence of mathematical relations between physical quantities. Moreover, we have here a peculiar asymmetry between the special and temporal co-ordinates; by this principle of determinism two temporally separate regions may influence each other physically; two spatially separated regions cannot.

The theoretical justification of this determinism arises from two circumstances. We shall mention these here without entering upon a mathematical proof that they really furnish this justification. In the first place, the physical laws—that is, the mathematical relations between the components of the field—are differential equations, and, in fact, to a first approximation, principally linear partial differential equations of the second order. In the second place, for the simplest four-dimensional geometry, in which the Pythagorean theorem remains valid, one must use, not the time itself, but the imaginary time, as fourth co-ordinate. If, instead of this, the four-dimensional manifold had four real dimensions, and the differential equation of physics remained unchanged, then we should have a much more complete determinism: one would then be able to deduce the state of any region of space-time from an accurate knowledge of any other specific region. If, on the other hand, the world had two real and two imaginary dimensions, there would be no determinism left. For in this case it would be possible for new motions suddenly to arise inside a box, even though there were no cause for them either within the box or at the boundary. This, then, is the significance of determinism for the physics of the field. It is not itself a natural law; the natural laws are the differential equations that lie at the basis of the physical field. It is a mathematical conclusion from these natural laws, a theorem from the mathematical theory of hyperbolic differential equations which has been applied to the laws of physics.

---

[1] *Habilitationsvortrag* at the University of Gottingen. Translated by Mr. Robert Oppenheimer. The author is very much obliged to Mr. Oppenheimer for his careful translation.

It is on this account that one must be prepared to lose this determinism in the transition from classical physics to the quantum theory. For just those physical assumptions are here discarded which we have noted as theoretical support for the existence of determinism. Even the *description* of 'physical reality' cannot, as we now know, be given in terms taken from classical physics. Physical quantities are *not* continuously propagated through space; physical motions are not invariably continuous; there are elementary discontinuities, there are *quantum jumps*. What remains of determinism is not necessarily more than statistical. If we work with a great many similar atoms, or repeat very often experiments with a few, then we always get a result in agreement with the principle of determinism. We have seen before that physical determinism and physical laws were not co-extensive. We must, therefore, remark that in this case what we have said for determinism holds also for all physical laws. All we know at present are laws that are essentially statistical.

In recent times important advances have been made in the discovery of these laws. One can now, for example, compute (in principle) the spectrum connected with the motion of electrons in an atom with the same assurance as, on classical dynamics, one could calculate the motions of the planets. But in spite of the analogy between the calculations, there is an important difference in the interpretation of their results. The classical calculation gives us information about our specific system of planets. The quantum theoretical calculation does not, in general, tell us anything about a single atom, but only about the mean properties of an assembly of similar atoms. One can, it is true, calculate the energy of a single atom in a certain state on the quantum theory. But that is only because the energy is the same for all atoms in this state, and the individual energy coincides with the mean. But if we consider the behaviour of the atom under external influences—*e.g.* incident light or electronic collision—we get a result that cannot be interpreted as showing that, for specific values of the phases, specific phenomena occur. We can only interpret the results of the calculation as follows: there is an assignable probability that the atom will do one thing, and an assignable probability that it will do any other.

We have a similar situation in optics. Classical optical theory yields, it is true, all interference phenomena in perfect accord with experiment. But the calculated intensity of light at a given point does not represent the actual intensity. The classical wave-field clearly only gives the probability that a quantum will reach the point. Moreover, one can find waves accompanying a material corpuscular beam which in some respects bear the same relation to the corpuscles as the light waves to the quanta. Here again we see the purely statistical nature of the present quantum theoretical laws.

We shall therefore direct our attention, not to the discrete, discontinuous details, but to the corresponding probabilities. The introduction of these probabilities brings us formally back to continuous variables, and thus, in a very important respect, to classical terms. We are therefore led to suppose that there is a principle of determinism for these continuous probabilities which is not very different from the classical principle. This is, in fact, the case, but in a somewhat more abstract way than in the classical theory.

It is known that Schrödinger, independently and by methods of his own, was able to give a formulation of the quantum theory which turned out to be mathematically equivalent to the matrix theory based on Heisenberg's ideas. He thus discovered mathematical relationships in the quantum theory, which had not before been explicitly developed. These were, it is true, implicitly involved in the matrix theory; but their formulation represents an important addition to quantum mechanics.

In connexion with these formulæ, Schrodinger also tried to develop a new physical basis for the quantum theory. His interpretation differs fundamentally from that of Planck, Bohr, and Einstein, from the classical quantum theory based on stationary states and quantum jumps. In it he tried to return to quasi-classical conceptions, in which there were no longer any discontinuities, and in which, therefore, the classical principle of determinism was still valid. All other scientific workers, however, who had taken part in the development of quantum mechanics, were unable to accept these speculations of Schrödinger. They were sure that the new conceptions would have to be interpreted physically in close analogy with the older notions of stationary states and quantum jumps, and with Heisenberg's theory; and that Schrödinger's relations would, like those of the matrix theory, have to be interpreted statistically. A particularly clear and satisfactory formulation of the statistical interpretation of Schrödinger's theory has been given by Born, and in what follows I shall base my argument on this.

The essential purport of Schrödinger's theory is this: that quantum mechanical laws, which were given in the matrix theory as a system of infinitely many equations with infinitely many unknowns, can instead be expressed by quite ordinary differential equations. Formally, this takes us back very close to the classical theory. Born's answer to the question as to how it is possible to represent anything in the discontinuous confusion of quantised atomic processes by differential equations, is that the function which is to satisfy the differential equation is a probability.

We shall now consider more closely this probability function, and try to make clear the analogy with the classical situation. Consider a mechanical system of two particles and six degrees of freedom; let the continuous co-ordinates of the particles be x_1, x_2 to z_1, z_2. We now construct a space more or less like the classical phase space, but with only half as many dimensions: a configuration space. In our example it is a six-dimensional space with the co-ordinates x_1 to z_2. We can represent the state of the system when it has specified co-ordinates and arbitrary momenta by a point in this space, which we shall call the system-point. Classically the system-point would describe a certain trajectory. But we cannot know beforehand, if we observe it at a given time at a given place in the space, how it will move, for the system-point only tells us the co-ordinates, not the momenta, of the two particles. All one can determine is the probability that the point will move in a given direction.

In the classical theory we can translate this statistical prediction into an exact one, since we can observe not merely the position but also the velocity of the system-point. But, according to Pauli, this is just the point where quantum and classical theory differ. If we can observe the co-ordinates of a quantum mechanical system—and here we use *co-ordinate* in a generalised sense, so as to include, say, the energy or the quantum numbers—then the momenta conjugate to these co-ordinates are intrinsically not observable. All we can do, therefore, is to take over the statistical problem from classical mechanics, and probably derive the solution from Schrödinger's differential equation. I say *probably*, because considerations which follow out these speculations are not yet completed.

The following question, however, which is closely connected with the one we have been considering, *can* be regarded as solved by the work of Born and Pauli. Suppose we know the energy and quantum numbers of our system—or, more generally, suppose we know the probability that the system is in any of the stationary states; what is the probability that the system-point is at a given place in the configuration space? We can answer this question at once if we know the Schrödinger wave function.

This Schrödinger function—a function of the six variables x_1 to z_2 and the time—satisfies Schrödinger's fundamental differential equation. For this probability function we can again formulate a principle of determinism. For this, of course, we have to take a box, not in ordinary space, but in the six-dimensional configuration space. Then the principle is precisely the same as in the classical theory, except that in place of the measurement of the field inside and on the boundary of the box we must now write the measurement of the Schrödinger probability function.

To recapitulate: classical physics described the world in terms of quantities continuously propagated in space and time. The quantum theory describes the world in terms of an abstract, many-dimensional configuration space, and the number of dimensions is proportional to the total number of particles in the world. In this abstract space we have again the propagation of continuous quantities; but these no longer tell us directly about the single atomic phenomenon, but rather about the probabilities of quantum processes. Determinism—not as a metaphysical distinction from chance, but in the physical sense explained above—has the same formal validity in both theories.

Of course, one can transform the quantum theoretical laws back to ordinary space, but their form is then very complicated, for the abstract space leads to the most suitable formulation of the problem. But one can still say that the complicated 3-dimensional predictions justify, roughly, what I said before—that in the mean the old 3-dimensional determinism still holds.

We have seen how it is possible, by the use of averages and probabilities, to eliminate the elementary discontinuities in physical processes, and to find relations which can be formulated mathematically by the customary methods of classical physics, methods adapted to the study of intrinsically continuous quantities. In this respect quantum mechanics constitutes a more precise version of Bohr's correspondence principle. Bohr always (it will be remembered), even in the zenith of our belief in integers, insisted that we try to establish a formal analogy with classical theory by a consideration of mean values.

Now, however, we shall return to the problem of the discontinuous elementary phenomena; we shall consider the question of how much we can say about these phenomena, granted that we can find the solution of any problem in averages, whatever their formulation. The answer to this question is not nearly so simple as one might expect; and I should be guilty of a very superficial treatment of my subject if I were not at least to point out some of the difficulties that occur in connexion with it.

Let us first of all examine the matter from the empirical point of view. One might suppose that experiments would in no case give us anything but average values. An interesting lecture given by Prof. Zernicke last summer on the Brownian movement, and in particular on the researches of Ising in Sweden, showed clearly the impassable limits to an improvement of the technique of physical measurement. It is impossible to increase the accuracy of a galvanometer, for example, beyond a certain assignable limit; it is impossible because of the Brownian movement in all parts of the apparatus. The needle, the fibres, the housing, the surrounding air, all consist of atoms in irregular thermal agitation; and the current that passes through the galvanometer consists of electrons, and therefore shows irregular variations of intensities, which can only be statistically computed and limit the efficiency of the instrument in an analogous way. When we remember that this is the case with all our apparatus, and that it all 'rattles about' in this way, we may be tempted to think that the experimentalist is quite as incapable of observing elementary processes as the quantum theorist is of predicting them. But there is a drastic method of avoiding Brownian movement. The theorist gives the simple recipe: make the experiments at the absolute zero. Luckily, experimentalists have discovered an equivalent but less uncomfortable way. By working with particles which have a vast store of energy, *e.g.* a fast α-particle, they make the thermal agitation of the atoms negligible. And we can, in fact, largely because of the work of C. T. R. Wilson, actually observe the fate of a single α-particle, follow its trajectory, and determine the moment when the trajectory ends in a quantum jump.

The time of a single quantum jump is thus under certain conditions a measurable quantity. What predictions can our theory make on this point? The most obvious answer is that the theory only gives averages, and can tell us, on the average, how many quantum jumps will occur in any interval of time. Thus, we must conclude, the theory gives the probability that a jump will occur at a given moment; and thus, so we might be led to conclude, the exact moment is indeterminate, and all we have is a probability for the jump. But this last conclusion does not necessarily follow from the preceding one; it is an additional hypothesis. It is this hypothesis which Bohr, Kramers, and Slater tried to carry out in their theory of radiation. They realised quite clearly that this hypothesis must leave the conservation of energy as only a statistical theorem. This conclusion, of course, was disproved by the beautiful experiments of Geiger and Bothe and of Compton. We can now assert that if an atom emits light, and that if this light is propagated, unhindered by interference, to another atom, where it is absorbed, then the quantum jump of the absorbing atom occurs after a time which corresponds exactly to the distance between the atoms. Thus we see that, in some cases at least, the time of a quantum jump is determined.

One might be tempted to say: the time is determined in so far as its determination is required for conservation of energy—and no further. But this two-sided explanation is too indefinite to be of any use in complicated cases, *e.g.* where interference occurs. Another method of overcoming this difficulty was tried some time ago by Wentzel: since in our example the absorption is fully determined by the preceding emission, we could regard the two processes together as a single quantum process, and then hope that such processes would be statistically independent of each other. But this way, too, does not seem to lead to any simple formulation.

It is thus very significant that in Pauli's above-mentioned formulation nothing is said about the probability of a transition—for we saw that this could not lead to independent probabilities. What the theory does specify is the probability that the system-point be at a given place in the configuration space. One might therefore hope that these considerations would lead us to independent elementary physical probabilities.

Although we can in principle compute all probabilities on the quantum theory, a very serious problem still remains unsolved. For definiteness let us take a simple example. Let us throw two dice; and let us observe empirically that a 1 and a 3 occur together just as often as a 4 and a 5, and twice as often as two 2's, and so on. Now if we had a theory which made it possible to compute these probabilities in some very complicated and abstract way, we might be satisfied. But we are really only satisfied when we can reduce the theory to this form; for each die each of the six faces is equally probable; and the dice are statistically independent. Only when we see this do we feel that we really understand the matter.

Now, for the dice we clearly should never think of using any other theory than the one just given. But in the quantum theory the matter is different: we can at present compute all probabilities; but we cannot understand any of them. We could only say that we understood them if we had translated the calculations in configuration space into the following terms: In some cases there is no condition on what happens; either this or that can happen; they are equally likely, and what happens in one case has nothing to do with what happens in others.

In other words, we must reduce the quantum theoretical probabilities to independent elementary probabilities. Only then can we say that we really understand the laws; and only then can we tell under what conditions the time of a transition is determined. Only then can we know exactly what is causally determined, and what is left to chance.

In conclusion, let me try to bring out one more point. We have just been taking for granted that the future analysis of quantum theoretical probabilities would lead to the result that certain elementary processes were not determinate, and could happen equally probably in a variety of ways. But in fact that is not at all self-evident. The circumstance that quantum laws are laws of averages, and can only be applied statistically to specific elementary processes, is not a conclusive proof that the elementary laws themselves can only be put in terms of probability.
